Mr. Russell has kindly supplied descriptions and illustrations of four cases of femoral hernia for my consideration. One is a particularly remarkable case; its sac was continuous with the peritoneum, yet it was not lined by peritoneum; how that sac was formed and how it became continuous with the abdominal cavity—unless it had been formed out of a "congenital" abscess cavity—I really cannot tell. My difficulty in accepting Mr. Russell's explanation—namely, that all four are of congenital origin—is that (1) we have no evidence in the thousands of bodies that have been dissected that there ever exists an empty congenital diverticulum of the peritoneum in the positions occupied by these sacs; and (2) no embryologist or anatomist has seen a trace of them in embryo or fetus. But my chief reason for refusing Mr. Russell's explanation is that such sacs can be produced experimentally in the dead body under the influence of agencies and conditions which we know are to be found in the living body. It would occupy too much space and time to detail these experiments now, but at some future time I hope space may be accorded me for the purpose in this journal. Meantime, I would recommend the supporters of the saccular theory to make observations on the following points if they wish to reach the truth about hernia: (1) The degree of intra-abdominal pressure which occurs in lifting heavy weights or in vigorous body movements; (2) the resistance power of the loosely fixed peritoneum in the regions where hernia occurs; (3) the resistance power of the femoral sheath—the sole structure which prevents the formation of a femoral hernia; (4) the functional meaning of the femoral canal.

There is one matter concerning which I would thankfully receive information. Is it true, as Mr. Russell asserts, that there is no relationship between the incidence of hernia and the occupation of those who suffer? I cannot lay my hand on exact data, but I have the impression, given me, I think, by Mr. W. McAdam Eccles, that bakers suffer in an undue proportion, and I believe the condition is also very frequent among labourers in brickfields.

I am, Sirs, yours faithfully,

ARTHUR KEITH.

March 18th, 1907.

* * Mr. Hamilton Russell has asked us to say that he feels that he cannot engage on equal terms in a newspaper controversy because of the time which must elapse before his communications can reach us, a point which we are sure those interested in this matter will recognise.—ED. L.

THE LATE PROFESSOR BUDIN'S METHOD OF REARING INFANTS.

To the Editors of *THE LANCET*.

SIRS,—In your review of my translation of Professor Budin's work, "The Nursing," the following statement is made: "The author excludes from his statistics all infants who have not attended at his clinic for at least one month. Would it be uncharitable to suggest that the newly-born infant who can survive a month's ordeal of undiluted sterilised milk might survive anything?"

As systematic supervision throughout infancy was the essence of Professor Budin's method of rearing children his statistics had to exclude all cases of less than a certain minimum duration. One month represented three to five attendances at the clinic, and no reliable conclusions could have been made as to the value of medical supervision if observation over shorter periods had been included. A mother needs to be educated to the fact that the fortnightly weighing and inspection of her healthy infant is worth the trouble it entails on her; the cases eliminated were almost without exception thriving infants whose mothers ceased to attend

after the clinic had lost its novelty. No infant was ever compelled to conform to any dietetic dogma by Professor Budin. He studied the feeding of each new patient as a fresh problem. I can confidently assert that none "were wrecked before the end of thirty days" from exposure to "an ordeal of undiluted sterilised milk," and if your reviewer wishes I shall gladly obtain for him the details of every case which attended Professor Budin's consultations for less than one month.

Thanking you for this opportunity to correct a false impression for which, perhaps, I am somewhat to blame, I am, Sirs, yours faithfully,

W. J. MALONEY, M.B. Edin.
Brook-street, Grosvenor-square, W., March 12th, 1907.

AN OPEN-AIR SCHOOL.

To the Editors of THE LANCET.

SIRS,—In the article by Mr. C. H. Garland and Dr. T. D. Lister on a National School for Consumptives we are told of the necessity for education in hygiene.¹ The education is to be confined, however, to the working class and to those suffering from tuberculosis. Should not a National School of Hygiene take into consideration a method of living which would prevent the commencement of disease? and is not the well-to-do class equally in need of instruction as to the duty and methods of healthy living? It is with the idea of forwarding such an education that I am erecting in Garden City the building which I am calling an open air school. It is an attempt to demonstrate the possibility of truly healthy conditions of living, not for invalids but for perfectly healthy persons, the result aimed at being to teach the possibility of preventing the first awakening of the germs of consumption.

This life is not to be (as was suggested in the article) "soft" more than any other life lived in the world. Open-air sleeping, eating, and bathing are to be combined with absolutely normal activities. It is proposed by rational feeding and reasonable intellectual and artistic development to produce a finer type of physique and a higher degree of mental and moral capacity than is at present known. I should gladly welcome any inquiry or any visit, though the building will not be complete for several months.

I am, Sirs, yours faithfully,

March 12th, 1907, A. J. LAWRENCE.

GRADUATED LABOUR IN SANATORIUMS.

To the Editors of THE LANCET.

SIRS,—Your readers may be interested to know that the system of graduated labour advocated by Mr. C. H. Garland and Dr. T. D. Lister in your issue of March 9th for patients in sanatoriums has been in force for two years in this institution with satisfactory results. I have had the pleasure of demonstrating this system both to Mr. Garland and Dr. Lister, and am glad to find they now advocate its general adoption. Again, the suggestion of these gentlemen that patients should be taught to take an intelligent interest in their treatment, and that the cause of the disease and methods of its prevention and arrest should be explained fully to each individual has been adopted here since the institution was opened. We have found, however, that "talks in the recreation room," when combined with close supervision of individual patients and continuous co-operation between doctors and patients, yield far more satisfactory results than any pamphlets or other literature, and in my experience amongst the working classes short individual conversations will do more good in a day than teaching by pamphlet will do in a month.

There is one paragraph in the article which appears to me to be original. I refer to the statement that "it is generally humiliating to a man to perform domestic duties..... like bed-making, floor-scrubbing, washing-up, and similar duties." An ounce of practice is worth a ton of theory. In our experience here we have never met this feeling of humiliation. Our male patients, when well enough to do so, make their own beds and keep their wards and crockery clean. They do this work cheerfully and well. The men of our navy, army, and mercantile marine, and men in other occupations daily perform such work as "bed-making,

floor-scrubbing, and washing-up." Are all these men suffering from a sense of humiliation?

I am, Sirs, yours faithfully,

M. S. PATERSON,
Brompton Hospital Sanatorium, Frimley, March 11th, 1907.

TREATMENT OF DISTENSION OF THE INTESTINES.

To the Editors of THE LANCET.

SIRS,—The treatment of distension of the intestines, whether following operation or otherwise, is always a matter of difficulty. There has been a considerable amount of correspondence upon the subject in your columns from time to time showing that the question is of importance. My object in writing is to protest against the treatment by puncture. I imagined that such a procedure was relegated to the past and that a student who suggested it at his examination would be sent down for six months. To my surprise I find that this is not so and I have just read in a clinical lecture by a physician at one of the leading London hospitals: "The prognosis of acute, gastric dilatation is, however, much better than that of tympanites, for while it is easy to evacuate a distended stomach by the tube it is very difficult to deal mechanically with distension of the intestines. The distended coils of intestine may, it is true, be punctured 'with impunity' (Italics are mine!) by a trocar and cannula, but the escape of gas by the cannula is barely sufficient to give permanent relief."

If this is the teaching which students receive it is not surprising that they should act in accordance with it. That they do is supported by the fact that I was recently called upon to operate on a case of septic peritonitis due to this cause. This, I think, is sufficient evidence to justify me in drawing attention to the subject.

I am, Sirs, yours faithfully,

J. LIONEL STRETTON,
Senior Surgeon, Kidderminster Infirmary and Children's Hospital.
March 15th, 1907.

ON THE CONDITION OF THE BLOOD-VESSELS DURING SHOCK.

To the Editors of THE LANCET.

SIRS,—Though firmly persuaded of the truth of Mark Pattison's saying that "of all the ways of wasting time controversy is the most unprofitable," I feel that I must beg space to reply to Mr. J. D. Malcolm's letter on this subject which appears in your issue of March 16th.

In any sphere of thought it is rare; in medicine it is conspicuously rare, for a theory to be found which will as once embrace all the facts. In the present state of our knowledge we have often to decide between two explanations which are diametrically opposed to one another, and in making our selection between them we have nothing to aid us except the weight of available evidence. Even where the preponderance of that evidence is overwhelmingly on one side, there are not infrequently irritating little facts which, for a time at any rate, decline to be included in the fold. It is facts of this nature upon which, in his tilt against the accepted explanation of the phenomena of shock, Mr. Malcolm has seemed to me unduly to dwell, to the exclusion of those matters of real import upon which the accepted explanation is based. If he wishes to persuade us not only that this explanation is wrong, but that it represents the exact opposite of the true one instead, of insisting upon differences in detail between two observers who are in complete consonance on the main question, Mr. Malcolm ought surely to begin by showing that there are fallacies in the arguments by which the present view is supported. Of these arguments I select one for his demolition. It is possibly not the most cogent of the many which might be adduced; it has, at any rate, the merit of simplicity. It is this. The sphygmomanometer shows that the blood pressure in shock is invariably subnormal.¹ The state of the blood pressure depends upon (a) the heart, and (b) the arteries. Mr. Malcolm has expressed himself satisfied² that the heart is not affected in shock. There remain therefore the arteries, including, of course, the arterioles. When these

¹ The Clinical Study of Blood Pressure, T. C. Janeway, 1904, p. 273.
² THE LANCET, March 16th, 1907, p. 762.

vessels contract the blood pressure rises, when they dilate the blood pressure falls.³ The only possible deduction from these elementary facts is that the general state of the blood-vessels in shock is that of dilatation. When Mr. Malcolm has exposed the fallacy in this argument and in others which might be presented in a similar form it will be time enough to consider his excursions into such by-paths as the effects of treatment of which his paper was composed.

Concerning the effects of treatment, it seems pertinent to inquire whether Mr. Malcolm's belief in his view of the contracted state of the blood-vessels in shock has ever induced him to exhibit full doses of nitrite of amyl in that condition. So prompt and reliable a vaso-dilator could hardly fail to produce a very impressive result.

I am, Sirs, yours faithfully,

London, W., March 16th, 1907.

LEONARD WILLIAMS.

FIRE AT THE ROYAL FREE HOSPITAL.

To the Editors of THE LANCET.

SIRS,—In order to allay anxiety on the part of friends of patients and others interested in the Royal Free Hospital which may result from the reports published in some of the newspapers respecting a small fire which occurred in one of the wards early on the morning of March 14th, I venture to ask you kindly to grant space for the following statement. The fire was caused by the joists under one of the fireplaces in the "Annie Zunt" Ward having become ignited. Owing, however, to the prompt action of the hospital staff and the fire brigade the fire was very quickly extinguished and none of the patients were seriously alarmed. I am glad to be able to state that the medical staff report that all the patients are entirely free from any ill-effects from what might have proved a very serious calamity. I may state that the hospital is fully equipped with fire-extinguishing appliances and all the porters and nursing staff are regularly drilled and instructed by an expert fireman in the use of the fire appliances.

I am, Sirs, yours faithfully,

C. W. THIES, Secretary.

Royal Free Hospital, London, W.C., March 15th, 1907.

THE POWERS OF MEDICAL OFFICERS OF HEALTH.

To the Editors of THE LANCET.

SIRS,—I take it the reason for the existence of the medical officer of health is that he may assist to the utmost of his power in stamping out, or, at least, scotching the inroad of, infectious diseases. But the medical officer of health has not the legal peremptory power to exercise this necessary function. He has to consider who it is that makes the complaint, whom the complaint is lodged against, and whether it will pay him to take up the case at all. He is not a free agent, with all his knowledge of sanitation; with all his convictions of the existence and dissemination of the death-dealing microbe, he must wait for it to assert itself, and he cannot, in many cases, forestall it by precautionary measures. I know of a case where a medical officer of health was appointed by a town council and the terms of his appointment were such as empowered it to "kick its own nigger." This was the actual expression used. The council did kick its own nigger and kicked him out of his office. There seems to me greatly to need an extension of the Act of Parliament giving to the medical officer of health absolute power of control for the repression to the extent of his ability of notifiable diseases. Of course, he would be still liable for damages in case of malicious interference. The public well-being demands it, even if the mayor or the town clerk kept pigs in a proscribed area.

To bring this closer home by an illustration of fact, I have lately been elected on to the committee of a mechanics' institution of over 4000 members. It is shockingly badly ventilated. I have applied to the medical officer of health. He cannot help me. It is a private institution. I have applied to him for a copy of the list of notified cases to hand over to the librarian to prevent the re-issue of books returned from an infectious case—for what is more natural than that a convalescent should seek readable books? He dares not give it to me. I have written the town clerk to strengthen his hand. He agrees that the consequences might be serious if the

medical officer of health did. I have written to the President of the Local Government Board two or three times. We have spotted fever near us and around; we are likely soon to have it. I have at last a letter this morning from the Assistant Secretary stating that the Board has no jurisdiction and cannot undertake to intervene in the matter of ventilation. With reference to the library, the Board is not aware of any statutory provisions requiring the medical officer of health to inform the committee of a library of the cases of infectious disease notified to him as the medical officer of health.

I believe I have heard that medical officers of health are themselves trying to get an increase of powers and a security of tenure of office in this independent direction. This seems to be a case that is recent and important enough to help them. An amendment to their Act seems necessary if anyone will undertake to get a Member of Parliament not to consent to wait until the mare is gone before to lock the stable door. I have myself retired from practice as a dental surgeon, and having no axe to grind shall be happy to place my facts and any assistance I can give at the disposal of anyone in thorough earnest on these matters of public health.

I am, Sirs, yours faithfully,

HENRY BLANDY, L.D.S. Edin., Irel., & Glasg.,

late Dental Surgeon to Nottingham General Hospital, Eye Infirmary, and Lenton and Euxton Orphanages.

112, Gregory Boulevard, Nottingham, March 17th, 1907.

YELLOW FEVER IN CUBA AND ITS MEANS OF PROPAGATION.

To the Editors of THE LANCET.

SIRS,—In reviewing my article on "Yellow Fever again in Cuba" in your editorial comment published in THE LANCET of Feb. 23rd, 1907, you have placed me in a wrong light and consequently made me suffer an injustice which, I am sure, was unintentionally done. The concluding words of your elucidation of my writing are the following: "His article is not without interest but will hardly modify the opinions of those who concluded with the several commissions that yellow fever is propagated by mosquitoes." These words give the wrong impression that I do not believe yellow fever is propagated by mosquitoes, and there is where you inadvertently have placed me in a false light. I have never denied that yellow fever is transmitted by mosquitoes. What I have always contended from the very first moment it was brought to public notice in Havana is the conclusion of the American Yellow Fever Commission in Cuba in 1900, that "the female mosquito of the species *Stegomyia fasciata* is the only and exclusive etiological cause, and the only and exclusive means of propagation of yellow fever." Which certainly is a very different thing from what you, unconsciously, accuse me of believing. I am of opinion that although mosquitoes, no doubt, transmit yellow fever under certain and well-defined conditions, yet there are besides other means of propagation of yellow fever—as, for instance, biting flies, bed-bugs, lice, chiggers, fleas, sand ticks, and other kinds of ticks. And it is very strange that no controlling experiments had been made with these domestic insects.

Another error in your kind review of my article is that the grand total of 89 cases of yellow fever, with 37 deaths (a death-rate of 41.57 per cent.) does not cover the whole year 1906, but only goes as far as July 1st; that is, to the end of the first six months of that year. During the second semester of 1906 a great many more cases of yellow fever occurred in Cuba.

I am, Sirs, yours faithfully,

A. M. FERNANDEZ DE YBARRA, A.B., M.D.

New York City, March 16th, 1907.

THE ELECTIONS OF GUARDIANS.

To the Editors of THE LANCET.

SIRS,—I think it a pity that Mr. J. Theodore Dodd, a guardian and councillor of the city of Oxford, should attempt to drag the vexed question of out-door relief into the columns of a medical journal. His axiom that infectious diseases, such as measles, whooping-cough, fevers of various descriptions, and phthisis, may be checked by being brought to the notice of a medical man at an early stage goes, of course, without saying, but when he launches out into the general question of "out-relief" I venture to submit that this is a very different

³ R. H. Starling: Elements of Human Physiology.

matter, and to suggest to the already heavily rated medical man that in view of the terrible abuses of this system which have been brought to light in a recent Local Government Board inquiry he will do well to pause before voting for guardians who are pledged to extend the facilities for this form of relief, thereby further pauperising the recipients and placing an extra burden on his own shoulders.

I am, Sirs, yours faithfully,

E. G. YOUNGER, M.D. BRUX., M.R.C.P. Lond., D.P.H.
Mecklenburgh-square, W.C., March 18th, 1907.

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

The General Hospital.

THE annual report of the board of management of the General Hospital shows a very satisfactory condition of affairs. The total expenditure for the year was £25,849 and the total income was £27,435, the latter being a little more than £1000 greater than the income of the previous year. On the other hand, it must be noted that the income derived from subscriptions, extra tickets, ordinary donations, and special congregational collections showed a slight, though distinct, falling off. During the year the daily average of in-patients was 304, the total number being 5204, and the cost per patient was £3 6s. 10d. Amongst the in-patients were included 1155 children under 12 years of age and of these 185 were less than two years old. The out-patients numbered 65,427, and each cost, exclusive of teeth extractions, 2s. The number of operations continues to increase; last year 3344 were performed, and as many are of a serious character they form a constantly increasing source of expense. The number of the out-patients is becoming so great that it constitutes a severe strain on the staff. Many of the cases are of quite a simple character, but their examination and treatment take time which might with advantage be devoted to more serious cases. This fact has been recognised for some time and steps are being taken to form a plan for the treatment of the more simple cases as dispensary or club patients. In the last annual report attention was drawn to a new plan for dealing with cases waiting for admission and the success of this is now recorded; it has worked so well that it is only at times of great pressure that any case has to wait a month before admission. It is stated in the report that many expressions of gratitude are received from patients and their friends but only a small minority of these are accompanied by contributions to the funds of the hospital.

The Walsall and District Hospital.

Considerable advances have been made at the hospital during the past year. Two additional wards have been built, and an additional operating theatre, a surgery for casualty cases, a new steam laundry, a disinfecting chamber, a new dispensary, and a more commodious x ray room have been provided. The income for the year exceeded the expenditure by £43, but it will have to be considerably increased next year if it is to cover the increased expenditure which will be necessary for the proper upkeep of the new departments, and the executive committee is wise in appealing at once for increased support.

The Care of the Feeble-minded.

At the annual meeting of the supporters of the Laundry and Homes of Industry, which attempt, amongst other things, to deal in a practical manner with the care of feeble-minded young women, Mrs. Hume Pinsent made an eloquent and forcible appeal for State interference. She pointed out that their society had proved that feeble-minded girls could be made useful and happy, but it was only possible to deal with a limited number. For this there were two reasons—want of means and absence of any power of legal restraint. Mrs. Pinsent emphasised the fact that the money extracted from ratepayers for the education of mentally defective children is practically thrown away, for when the school period is over there is practically no safe place to which the girls can go, and none to which they can be made to go, the result being that both they and their children have eventually to be kept at the public expense. Voluntary subscriptions have hitherto proved utterly inadequate to meet the necessities and with the regularly increasing burden of rates and taxes out of all proportion to the general increase of incomes, it

is not likely that voluntary subscriptions will increase to any great extent. It is perhaps not to be wished that they should, for if there is any chance of staving off the consideration of a difficult subject Governments are not likely to interfere where no votes are to be gained, and it is important that this should become a prominent question, for the feeble-minded and the insane are two great dangers which threaten the best interests of the State, and at present no adequate provision is made for dealing properly with either the one or the other, while both might be practically eradicated in a comparatively short time if they were dealt with in a firm and efficient manner.

Measles and Diphtheria.

We are suffering at present from a very definite epidemic of measles and it has been found necessary to close many schools. During the past week there were 19 deaths from this disease, and there do not seem to be any signs of diminution. Diphtheria also continues to be very prevalent but fortunately it is still of a very mild type. Scarlet fever has diminished but typhoid fever shows signs of increased activity.

March 19th.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

Ladies Charity and Lying-in Hospital.

THE annual meeting of the supporters of this charity was held last week at the town hall under the presidency of the Lord Mayor. The board of management reported that, owing to the improved condition of the working classes of the city, the number of patients attended to in the outdoor department was only 1645, as against 1847 in the previous year. The number of in-patients was 295, as against 322 in the year 1905. In the school of midwifery 57 pupils were trained during the year; these attended the examination of the Central Midwives Board in accordance with the new Act, of whom 54 qualified. Professor A. M. Paterson, in moving a vote of thanks to the board of management and the medical staff, emphasised the fact that the charity was doing a great work, not merely for the relief of the poor but also in an educational sense, and this had been brought about through the harmonious feeling that existed between the charity and the University of Liverpool. Mr. J. B. Fortune had provided an operating table for the hospital. Lady Hampson had raised among her friends £564 to provide necessities for the patients without trenching on the honorary treasurer's funds. The out-door department is now fully utilised by the medical students at the University for the purposes of practical midwifery under the supervision of Professor Henry Briggs.

The Proposed New Dental Hospital.

The committee of the Liverpool Dental Hospital has decided to make a public appeal for the erection of a new hospital. The present building—which is a converted dwelling-house in Mount Pleasant and has been used as a hospital for nearly 30 years—is now totally inadequate for the needs of the charity. It has been altered and enlarged from time to time until now all the available space is occupied. In every respect the accommodation is insufficient. The space available for operating-rooms and laboratories is also far too limited. The sanitary condition of the hospital is unsatisfactory. This hospital is the only dental hospital in Liverpool and is largely used by the poor of the city. During the year 1906, 23,982 patients were treated. Over 30,000 operations were performed and of these about 11,000 were operations not for the extraction but for the preservation of the teeth. With more adequate appliances and accommodation the number of operations in this category would be greatly increased. The Dental Hospital is affiliated to the University of Liverpool through the school of dental surgery, the dean of which has a seat at the medical faculty. By this means of two important ends are gained. Without the assistance of the students the greater portion of the work accomplished could not be undertaken by the staff of the hospital, and without the practice of the hospital the school of dental surgery could not exist. It is estimated that the cost of a new hospital will be about £10,000, including equipment. Promises of support already received amount to over £5676,

towards which the hospital staff and school fund have contributed £1000.

The Liverpool Stanley Hospital.

The annual meeting of the subscribers to the Liverpool Stanley Hospital was held at the town hall on March 9th, under the chairmanship of the Lord Mayor. One of the features of the report was the recent creation of a gynaecological department, to which Miss M. H. F. Ivens, M.B., M.S. Lond., was appointed the gynaecologist. A special ward to contain six beds was being built in connexion with this department, but the committee had decided that the total number of beds in use at the hospital should not be increased till the existing debt was removed. The cost of the new ward had been defrayed by, and was dedicated to the memory of, Mrs. J. H. Thom. It was the wish of the donor that the post should be filled by a lady practitioner.

Cerebro-spinal Meningitis and Notification.

At a meeting of the city council held on March 6th, the following motion was carried:—

That the council, as the urban sanitary authority of the city of Liverpool, do order that the provisions of the Infectious Disease (Notification) Act, 1853, shall apply in their district for six months to cerebro-spinal meningitis, and that such order shall come into operation immediately after the expiration of one week after the publication of first advertisement of the order as approved by the Local Government Board.

Notice has been given that the above order was approved by the Local Government Board on March 12th, 1907.

Sir Rubert Boyce's Illness.

Professor Sir Rubert Boyce has written to the chairman of the Liverpool School of Tropical Medicine (Sir Alfred Jones) under date of Feb. 27th from Grand Canary, saying that his health is daily improving.

The University of Liverpool and Physical Anthropology.

It is proposed to establish a lectureship in physical anthropology at the University. With the material available in the University and in the city museum the establishment of such a lectureship would do much to stimulate interest in the subject in its many branches.

March 15th.

WALES AND WESTERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENTS.)

Infantile Mortality in Cardiff.

At a meeting of the Cardiff corporation held in December, 1906, some members appear to have been unduly alarmed at what they described as the high rate of infant mortality in Cardiff during the third quarter of the year, and Dr. E. Walford, the medical officer of health, was instructed to inquire more fully into the causes of this high rate. In the special report on the subject, which has recently been issued by Dr. Walford, he points out that although the infantile mortality-rate in Cardiff during the third quarter of 1906 was 154 per 1000 births it must be kept in mind that the rate in the 78 large towns during the same period was 209 per 1000 and that for the whole of the year the Cardiff rate was only 134 per 1000. He points out that one third of the total number of deaths of young children was due to diarrhoeal diseases and the recommendations which he makes are chiefly concerned with lessening the incidence of these diseases. He very prudently refuses to attribute the presence of diarrhoea among children to one specific cause, the removal of which will remove the disease. While admitting that a most important direct cause is improper feeding, he refers to the fact that the highest rate of infantile mortality occurs in the central districts of the town in which the density of the population is the highest and in which the housing accommodation and general sanitation compare unfavourably with the newer districts, where the streets and buildings have been laid out in accordance with modern ideas. He also lays stress upon the importance of the special cleansing of streets and the flushing of street gullies in hot weather, as well as on the importance of reducing the amount of dust caused by tramcars, motor-cars, and other vehicles. Among his specific recommendations are the appointment of additional women inspectors (there is at present only one in Cardiff), the control and supervision of milk supplied to infants artificially fed, and the provision of more complete statutory control over the milk-supply.

Cardiff Infirmary.

The committee of management of the Cardiff Infirmary has issued a strong appeal for £30,000 to be employed in making several much-needed additions to the institution. It is proposed to erect a new pavilion to contain 64 beds, a new gynaecological operating-room, a clinical laboratory, a museum, and a new post-mortem room.

Public Health in Aberystwyth.

Dr. Abraham Thomas in his annual report to the town council of Aberystwyth stated that the number of births was 172, compared with an average of 173 for the decade, and that there were 143 deaths, compared with an average of 140 for the decade. Infantile mortality was equivalent to the very high rate of 183 deaths per 1000 births registered. It was remarkable that in a health resort like Aberystwyth, with all its natural and hygienic advantages, the infant mortality should be higher than in the large industrial centres of England. Proper care and attention to the feeding of infants would result in a large saving of infant life and rapidly lower the death-rate. The total number of deaths from zymotic diseases at Aberystwyth during the past ten years was 92, which was equivalent to an annual zymotic death-rate of 1.14 per 1000. Some of the infectious diseases were imported by visitors and the absence of an isolation hospital entailed loss and hardship on lodging-house keepers. In the interests of the town as a watering-place and educational centre the provision of hospital accommodation for infectious cases was absolutely imperative. The drainage system was satisfactory and the quality of the water-supply was above suspicion. The meteorological records showed the remarkable evenness of temperature which prevailed at Aberystwyth and practically extended throughout the whole year, so much so that the winter temperature approaches that of the south coast health resorts. The climate, despite its mildness, was bracing and suitable for convalescents to recruit their health and strength.

The Adulteration of Cider.

The increased consumption of cider outside the counties in which the cider apples are grown is no doubt responsible to a great extent for the amount of adulteration which this beverage is said to undergo. During the past two years the National Fruit and Cider Institute has been making investigations as to the purity of the cider which is being sold. As a result it has been found that salicylic acid is being widely used as a preservative, while in some samples of cider no apple juice has been present at all. Although cider is commonly supposed to be pure apple juice it appears that difficulties have arisen in preventing the addition of other substances through the absence of any precise definition. A representation has recently been made by cider makers in the western counties to the President of the Local Government Board and the President of the Board of Agriculture and Fisheries asking that pure cider should be defined and that steps should be taken to prevent its adulteration.

Reform of the Poor Laws.

In making suggestions to the Poor-law Commission for the reform of the Poor laws the Bristol board of guardians has very properly distinguished between habitual vagrants and *bona-fide* workmen in search of work. In the opinion of the board the former should be detained in State labour colonies long enough to secure some reformation of character, while the latter only should be lodged in the workhouses and passed on with way tickets entitling them to food and lodging in neighbouring workhouses. A further suggestion of the Bristol board is that the provision made for the destitute should be restricted to necessities and should be less agreeable than the lot of the self-maintaining labourer, although the sick, the imbeciles, and the children, who are not responsible for their position, should be well cared for.

Sanitary Matters in the Tavistock Rural District.

At the meeting of the Tavistock (Devon) rural district council held on March 15th a letter was read from the Local Government Board stating that it cannot regard as satisfactory the reply of the council to the report of Dr. R. Deane Sweeting. The Board specifies several urgently needed sanitary improvements mentioned in Dr. Sweeting's report and asks what steps the council is taking to carry Dr. Sweeting's recommendations into effect. The Local Government Board adds that after a full consideration of Mr. O. O. Brodick's reply to the criticisms on the performance of his duties as medical officer of health the Board cannot regard

At an Inquest held in Belfast on March 12th in reference to the death of an infant, four months old, in Longford-court, was not seen by any medical man, it came out in evidence that in the same place the mother had lost another child who suffered from the same symptoms. After

this occurrence the house was fumigated by the health authorities. The police sergeant said that the yard of the house in which this family lived was in a perfectly filthy state and the place generally was unfit for human habitation, adding that it had been closed some time ago, but had since been reopened. The coroner said that the place appeared to be greatly overcrowded and recommended the jury to advise the sanitary authorities to look into the matter. He ascribed the high death-rate of the city of Belfast to poverty more than anything else..

Lisburn Water-supply.

At the monthly meeting of the Lisburn rural council it was reported by the council's analyst that the water taken from the Killullagh river was dangerous and quite unfit for cattle. It appears that this condition is due to the washings of the filter beds of the Stoneford water area being discharged into the river in an unpurified condition. The council threatens to institute legal proceedings against the Belfast Water Commissioners unless they abate the nuisance.

Queen Alexandra Sanatorium at Davos.

On March 15th, in the City Hall, Belfast, the Lord Mayor (Lord Shaftesbury) presiding, Lord Balfour of Burleigh brought the claims of the new sanatorium at Davos before a large Belfast audience and asked for support. Professor J. A. Lindsay having referred to the climate, other speakers followed and a considerable sum of money was promised for this deserving object.

Queen's College, Belfast.

The fifth annual dinner of past and present students of Queen's College, Belfast, was held on the eve of St. Patrick's Day, March 16th, in the examination hall of the College, Sir John W. Byers presiding, when there was a very large attendance of professors, graduates, and students. Sir John Byers gave some interesting reminiscences of the College, contrasting its present condition with what it was when he first entered as an arts student. He referred to some of his fellow-students who had shed lustre on the College, such as Dr. Joseph Larmor, Lucasian Professor of Mathematics at Cambridge; Dr. Leslie Porter, Commissioner in the Lucknow United Provinces; and Sir John N. Jordan, K.O.M.G., Minister at Pekin. Other speakers were Dr. J. W. Browne, the President of Queen's College, Professor W. St. Clair Symmers, Professor Johnson Symington, Professor G. Wilson, Professor J. A. Lindsay, and Sir Otto Jaffa. The dinner, which was well attended, was a great success.

The Belfast Ophthalmic Institution.

At the annual meeting of the supporters of this hospital held on March 18th the report submitted showed that 1492 extern eye and 754 ear, nose, and throat patients were treated during the year and 174 cases were received into the wards. The improvement and refitting of the extern department are urged by the staff at an expense of about £250, and of this Dr. J. Walton Browne (senior surgeon) announced that a friend had promised £50. Financially, the amount due to the bank has been reduced to a little over £100, and as to yearly expenditure there was a shortage of £60 3s. 11d. Several speakers referred to the admirable work done at the hospital.

Cerebro-spinal Fever.

Up to to-day (March 19th) 186 cases have been notified with 105 deaths.

Ulster Hospital for Women and Children.

At the annual meeting of the supporters of this hospital held on March 11th it was reported that there had been of intern patients 247 children and 81 women. There had been in the out-patient department 2584 children (of whom 837 were eye cases) and 609 women. There were six intern and 260 extern maternity cases. The rebuilding of the hospital was urged. The only change in the medical staff is that Mr. H. H. B. Cunningham replaces Dr. O. E. Shaw as ophthalmic surgeon. Financially, the total income for the past year was £1217 9s. 8d. and the expenditure was £1163 8s. 9d., leaving a balance in hand of £84 3s. 4d. Mr. G. W. Wolff, M.P., has promised £1000 on condition that all the money (£10,000) is secured for erecting the new hospital before commencing work.

March 19th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Radiotherapy and Spasmodic Spinal Paralysis.

M. Babiniski recently published an account of a case in which he had obtained a successful result from radiotherapy. The case was that of a child, aged 15 years, who, after a motor-car accident, suffered from general spastic contractions of the neck, the trunk, and all four limbs. A spinal hæmorrhage or pachymeningitis was suspected. At the meeting of the Hospital Medical Society, held on March 1st, M. Babiniski brought forward a somewhat similar case. The patient, a woman, aged 24 years, suffered from contractions of the legs, with paralysis and involuntary spastic movements. The tendon reflexes were exaggerated, there was spinal epilepsy, and the great toe sign was obtainable. 12 sittings for radiotherapy brought about considerable improvement. Except in the cases of Pott's disease or of syphilitic spinal paralysis no other kind of spasmodic paralysis has run a similar course. M. Babiniski considered that the woman had either a patch of spinal sclerosis or else a sarcoma compressing the spinal cord.

Stripping off the Pulmonary Pleura.

On March 5th M. Delorme read before the Academy of Medicine a paper dealing with the case of a patient, under the care of M. Picqué, who had an empyema due to a knife stab. For this he was operated upon three times but the wound did not heal. M. Picqué thereupon cut down on to the contracted lung and stripped off the thickened and inelastic pleura which prevented expansion of the lung, with the result that very soon the patient was perfectly well. M. Delorme discussed the indications for this procedure which he was the first to advocate. Stripping off the pleura should be employed only in cases of diffuse empyema where the two surfaces, visceral and thoracic, of the pleura are separated to an extent of at least six centimetres. Moreover, the operation should not be done unless respiratory gymnastics, begun a few days after the operation for empyema, have failed to make the lung expand. Empyemata starting from simple outside infection seem to give better results than those which are consecutive to pleuro-pulmonary infections.

The Radiotherapy of Chronic and Gonorrhœal Rheumatism.

M. Dominici and M. Gy have been making researches into this subject and the results thereof were presented to the Academy of Medicine on March 5th in a paper read by M. Albert Robin. M. Dominici and M. Gy made use of metal screens or squares of cloth to which the radio active substances were fixed by means of varnish. They came to the conclusion that radium exercises a remarkable influence for good in either form of rheumatism treated. The oedema, the pain, and the reflex contractions all disappeared. The joints rapidly regained their proper functions and as a consequence the muscular dystrophy gradually disappeared also.

The Antitoxic Role played by Calcium Chloride in Bright's Disease.

At the meeting of the Biological Society held on Feb. 23rd M. Iscovesco read a paper on the above subject. He stated that he had found that patients suffering from Bright's disease of the non-polyuric form but who passed from three to 15 grammes of albumin per litre showed a very considerably diminished globular resistance and their serum was very hæmolytic. If, however, calcium salts were added to the serum of these patients the hæmolytic power was diminished or even suppressed altogether. He therefore gave a number of patients coming into the above category chloride of calcium by the mouth in doses of from 20 to 75 centigrammes per diem. In all the cases the amount of albumin excreted was diminished; in one case at the end of a month it had fallen from 8 grammes per litre to 1.50 grammes. In another the amount fell from 12 grammes per litre to 1.50 grammes. The general condition of the patients also improved and the hæmolytic power of the serum diminished. M. Iscovesco could not find any case in which the albuminuria disappeared altogether. In his opinion albuminuria depends upon two factors, the one renal, on which calcium chloride exerts no influence, and the other has to do with the blood. It is upon this last that calcium chloride acts so well. Milk has long been recommended as a

most suitable food for albuminurics and it may be that its suitability is due to the calcium salts which it contains.

Le Certificat d'Études Médicales Supérieures.

IN THE LANCET of Nov. 24th, 1906, p. 1477, I gave your readers some account of the various protests made by the French medical profession against the decree creating the *certificat d'études médicales supérieures* which dated from July 25th, 1906. The great objection was to the title which it was thought would make the public believe, though wrongly, that the holders of this certificate possessed superior medical knowledge to that of those who did not possess it. The opponents of the decree have now gained the day, for the President of the Republic has just issued another decree making the certificate in question null and void. The Minister of Public Instruction has, for his part, appointed an extra-Parliamentary Commission of 73 members to inquire into the question of what modification can be imported into the organisation of medical studies as at present existing.

March 18th.

SWITZERLAND.

(FROM OUR OWN CORRESPONDENT.)

New University Buildings in Zürich.

VERY important enlargements of the premises occupied by the University of Zürich and its scientific and clinical annexes are being planned at a cost of about £300,000. The first series of buildings proposed by a scientific committee headed by the professor of zoology, Mr. Lang, will be commenced as soon as the necessary credit has been granted by public vote to the cantonal and town authorities. This series consists of a new university building which is to occupy a prominent position near the Federal Polytechnic School; it will be an imposing structure and is to cost £150,000. Next to it the Zoological Institute is to be erected at a cost of £57,000 and last, but not least, a new building for hygiene and bacteriology costing £28,000. There is some anxiety in university circles as to whether the inhabitants of the canton of Zürich, already burdened by heavy direct taxation, will grant these considerable sums of money, because later a further grant of some £80,000 will be required for new isolation wards and for the enlargement of the surgical wards and the Institute for Physical Therapeutics. The inhabitants of Zürich regard with no very favourable eye the increase of foreign students, especially Russians, which increase is partly responsible for these new structures. The University of Zürich has at present 1339 regular students and 336 "Auditoren" who only attend a few lectures. Of the 1339 regular students only 578 are Swiss, the remaining 763, who, of course, form the majority, being foreigners. The Russian students are quite to the front, with 455 male and female students, just numbering one-third of all the students. The question is being raised whether this number should not be reduced by new legislative steps.

Therapeutics of Scarlet Fever.

At a meeting of the Society of Zürich Practitioners, held on March 7th, Dr. Theodore Zangger read a paper on the Pathology and Therapeutics of Scarlet Fever. He gave some interesting details about the mortality of this disease in Zürich. In the years 1904 and 1905 the endemic prevalence of scarlet fever, from which some 300 patients suffer every year (the population of Zürich is 170,000), took an epidemic form, 1321 and 1468 cases being announced to the sanitary authorities. No doubt several hundred cases in these years escaped notification through being treated at home without medical aid or by quacks. The majority of cases were treated at the Cantonal Hospital under Professor Eichhorst. In 1904 there were 15 deaths and in 1905 there were 23 deaths. For 2789 cases this gives a mortality of scarcely 1.5 per cent., a very low average when compared with other statistics. Dr. Zangger proposed more active treatment for all cases of scarlet fever in the form of a spray of a 2 or 3 per cent. solution of peroxide of hydrogen applied to the nostrils and throat twice a day so long as abnormal secretion and inflammation continued. Wet packs and baths also form part of this treatment which gave good results as regards complications.

March 11th.

Obituary.

ARTHUR ERNEST SANSOM, M.D. LOND., F.R.C.P. LOND.,
CONSULTING PHYSICIAN TO THE LONDON HOSPITAL.

THE announcement of the death of Dr. A. E. Sansom will be received by his many friends with very deep regret. He had been in failing health for some years and retired from active practice about two and a half years before his death, residing first at Hampstead and subsequently at Bournemouth, where he died on March 10th.

Arthur Ernest Sansom was born at Corsham, Wiltshire, on May 13th, 1838. His father was a gentleman farmer; his mother a lineal descendant of the celebrated divine, Dr. Isaac Barrow. He was educated at Queenwood College, Stockbridge, Hants, where he had the advantage of studying under Professor Tyndall. On leaving school he was under the care of a private tutor at Chippenham in order to prepare for the University of London. He entered King's College, London, at the age of 16 years, at which institution he became Warneford scholar, in addition to gaining many other prizes and successes. He afterwards acted as clinical clerk to the late Dr. Todd. After filling the usual out-patient and in-patient appointments, and being then too young to obtain his diplomas, he proceeded to Paris in order to study at the Hôpital St. Louis, and was a devoted disciple of Poirry. He became a Fellow of King's College. He took the diplomas of M.R.C.S. Eng. and L.S.A. in 1859. In the same year he obtained the degree of Bachelor of Medicine of the University of London and that of Doctor of Medicine in 1866. He was elected a Fellow of the Royal College of Physicians of London in 1878.

Dr. Sansom held the post of assistant physician and subsequently that of physician to the London Hospital and to the North-Eastern Hospital for Children and at the time of his death he was consulting physician to both these institutions. He had also held the appointment of physician to the Royal Albert Orphan Asylum and physician to the Royal Hospital for Diseases of the Chest, City-road. His earlier works were: *Chloroform: its Action and Administration*, published in 1865; and *Anæsthetics in Obstetric Practice*, published in 1869, in which he advocated the more general use of a mixture of chloroform and of absolute alcohol. He was the first member of the medical profession in this country to bring before his colleagues the important deductions from Pasteur's researches in fermentation, but his papers read before the Medical Society of London were not received with the favour which they deserved and their embodiment in book form entitled "The Antiseptic System" met with no encouragement. His insight into a subject which was in the future to cause a revolution in surgical practice was, however, remarkable, and the correctness of his views was subsequently confirmed by the researches of Mr. (now Lord) Lister. His best known work was entitled "The Diagnosis of Diseases of the Heart and Thoracic Aorta," published in 1892, and is recognised as one of the standard works on the subject. His valuable researches and observations on diseases of the heart were further recorded in the Lettsomian lectures on the Treatment of Some of the Forms of Valvular Disease of the Heart and also in his articles in Keating's *Cyclopædia of Diseases of Children*, Quain's "Dictionary of Medicine," the "Twentieth Century of Practice of Medicine," and Allbutt's "System of Medicine." These publications proved him to be one of the leading authorities on diseases of the heart.

In all his writings Dr. Sansom's earnest desire was to inculcate precision—precision of observation and precision of record. He was accustomed to lay particular stress on practical points in diagnosis and treatment. He took infinite pains to procure accurate records of tracings obtained by the sphygmograph and cardiograph. His published works afford ample proof of his labours in this direction. Another feature of his book on "The Diagnosis of Diseases of the Heart" is the numerous reproductions of outlines of the heart and positions of the physical signs as obtained from superficial tracings taken from the actual chest wall in cases of heart disease. His former house physicians or those students who accompanied him in his visits to the wards of the London Hospital will remember the enthusiasm and perseverance with which he obtained such tracings and the pains which he took to explain to those around him the significance and importance which

ARTHUR ERNEST SANSON, M.D. LOND., F.R.C.P. LOND.,
CONSULTING PHYSICIAN TO THE LONDON HOSPITAL.

he attached to them. Dr. Sansom was a keen supporter of the various medical societies. He was constant in his attendance at many of them and frequently took part in the discussions. He was a past President of the Medical Society. He was also a corresponding member of several foreign societies.

Dr. Sansom was possessed of a most charming personality. His kindness and geniality made him beloved by all who knew him. No one can forget the warmth of his greeting and his true friendliness towards those who were privileged to have a close acquaintance with him. He was a staunch Churchman and in a quiet unostentatious manner performed countless acts of charity and was willing to lend a helping hand to those who required assistance by money, time, and advice. When he retired from practice he caused a gap which was difficult to fill and he left Harley-street amidst the sincere sympathy and regret of his numerous friends. Dr. Sansom was an ardent Freemason and his services to the craft obtained for him the well-deserved honour of Senior Grand Deacon in the Grand Lodge of England in 1902. He took a deep interest in many charitable institutions, especially in the work connected with Epsom College. Dr. Sansom married Miss Weaver, daughter of Mr. Henry Weaver, of Devizes, county surveyor of Wiltshire, who survives him. He leaves six children, his eldest son and his son-in-law being members of the medical profession and his second son practising as a dentist.

The funeral took place on March 14th. The first part of the service was conducted at St. Luke's Church, Hampstead, and many old friends attended to attest their sorrow for the loss of one so largely beloved and respected. The interment followed at Finchley Cemetery.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr. Clemente J. dos Santos Pinto, professor of operative medicine in the Oporto School of Medicine.—Dr. Paul Krabler, extraordinary professor of children's diseases and of internal medicine in the University of Greifswald.—Dr. Warenhorst Pasha, senior medical officer of the Deaconesses' Hospital, Alexandria.—Dr. Mathias Duval, professor of histology in the University of Paris and member of the Academy of Medicine.—Dr. F. J. Herrgott, formerly professor of clinical midwifery in Nancy.—Dr. Georg Friedrich Louis Thomas, professor of pharmacology and director of the University Medical Policlinic, Freiburg, at the age of 68 years. In the earlier days of his professional life he was assistant to Dr. Strempel, professor of surgery in Rostock, and afterwards to Wunderlich, the celebrated Leipzig professor of medicine. He was the author of many articles in Ziemssen's "Handbuch" of Special Pathology and Therapeutics.—Dr. Adalbert Tilkowsky, director of the Lower Austrian Lunatic Asylum, Vienna, aged 67 years.

VIENNA.

(FROM OUR OWN CORRESPONDENT.)

Anthrax in Vienna.

AN epidemic of anthrax, which was quickly extinguished by the energetic measures of the sanitary board, occurred not long ago in this city. The source of infection was found to be hair imported from Russia and the first patient was a carpenter who in his spare time used to make brushes. His wife also contracted the disease from the same source, and four other persons who had all been associated with the two first patients were afterwards attacked. Among these six patients, who were all admitted to hospital, there were four deaths. Before the infected hair—horsehair used for upholstery and brushes—was identified, a careful examination of the cattle in the slaughter-houses of Vienna was made and one case of anthrax was found. Disinfection on a large scale was employed. The difficulty of checking the spread of the disease lay in the fact that many people work at the business at home, especially girls and children, who earn pocket-money by tying the hair in small bundles for sale. The authorities, however, succeeded in tracing all the hair coming from the suspected parcel and seven days have now elapsed since the last case was reported.

New Regulations for the Disinfection of Books and Garments.

A series of new regulations, according to the *Journal of the Sanitary Board*, has been issued with regard to the disinfection of books from circulating libraries and of theatrical costumes if they are worn by different persons. Experiments have shown that there is no absolutely certain method of disinfecting books, but an exposure of two or three hours' duration to the vapour evolved from formalin will not damage the book, whilst it will lessen the virulence of bacteria. The present epidemic of influenza may supply an opportunity of testing the efficacy of the method, because it is well known that many of the adult patients have been in the habit of reading books obtained from lending libraries. Although a clause of the regulations requires notification to the proprietor of any case of illness among the readers, there is no means of insuring that this precaution is observed, and it is therefore now directed that every book returned to the library must be placed standing open in a receptacle or room, where an atmosphere of the vapour given off by formalin is allowed to act on it. Theatrical garments and costumes must be disinfected in a similar way before being handed to a second person for wearing. An action for damages which was recently heard before the High Court of Justice was brought by an actress who alleged that she contracted scabies by wearing an article of dress in which she had to appear on the stage. The action was unsuccessful but the calling of public attention to the matter resulted in the renewal of the old regulation.

Left-handedness and Epilepsy.

In a paper read at a recent meeting of the Medical Society Dr. Redlich discussed the condition known as left-handedness. His observations showed that about 2 per cent. of all men were left-handed, whilst the percentage for the female sex was slightly higher. Among neurotic and mentally unsound persons the proportion of left-handedness was much higher—namely, 8 per cent.—whilst among 125 juvenile epileptics there were 22 left-handed, or a proportion of 17 per cent., and both sexes were equally affected. In ten cases the patients themselves were right-handed, but in their families left-handedness was present. It was possible to distinguish between left-handedness affecting families and that which was of solitary occurrence. Whilst in the majority of cases the aberration from the rule of right-handedness was of a family type, the epileptics showed solitary occurrences in 15 per cent. of the cases and only this form was to be regarded as pathological. The pathological importance of this abnormality in epileptics was proved by the concurring symptoms of unilateral degeneration and of asymmetric development of the face and skull with predominance of the right side of the brain. Left-handedness in epileptics might therefore be explained as an extremely slight degree of paralysis of the right side of the body. Another type of left-handedness, which might be called the secondary type, was due to injury of the cerebral tissue controlling the right upper extremity, such injury having occurred either during foetal life or in very early infancy, so that an actual paralysis was never observed. Lesions of this kind might be produced by congenital syphilis, by infectious diseases, by meningitis, and by traumatic incidents during labour. Such primary lesions in the brain might prove a centre for the irritation which later in life produced epileptic seizures, so that the frequency of combination of left-handedness and epilepsy was more easily understood. Left-handedness was more often anatomical than functional. In the measurements of the muscles and bones of the upper extremities there was a difference of a centimetre or one and a half centimetres in favour of the left side, and the condition was often masked by the fact that numerous handicrafts and most machines were so arranged as to be worked by the right hand only, and in this way the right hand was made to appear the more useful of the two. But an examination of other organs, such as the eye and the ear, and of the general sensibility, would show that they were better developed on the left side if the individual were left-handed.

Congenital Dilatation of the Colon in a Child.

A case of this rare congenital abnormality was shown at a recent meeting of the Wiener Gesellschaft der Aerzte by Dr. Weiss who had had the patient, now a boy three years of age, under observation from the time of his birth. During the first week of his life he suffered from constipation, incessant vomiting, and a remarkable dilatation of the abdomen. In the second month, however, the alarming

symptoms subsided and the child had a period of six months of good progress, during which his weight reached 7 kilogrammes (15 pounds). Then suddenly the old symptoms re-appeared, the abdomen becoming tympanitic and so tense that the skin was shiny. After repeated irrigations enormous quantities of fecal matter and faecal concretions were expelled. The weight of the child fell to 6 kilogrammes and up to his twentieth month he never gained any ground and his weight remained constantly at the same level. In the third year the parents had finally consented to an operation, which would be performed at an early date. Meanwhile the boy was shown with all the symptoms of the disease present. Examination per rectum revealed an enormously dilated rectum and sigmoid flexure without any associated stenosis, and the flaccid abdominal wall allowed the dimensions of the colon to be measured approximately, the estimated circumference being 20 centimetres (eight inches). The operation to be performed would consist in resection of the permanently dilated part of the colon.

March 18th.

CONSTANTINOPLE.

(FROM OUR OWN CORRESPONDENT.)

A Gratuitous Dispensary for Tuberculous Patients.

THERE exists in Constantinople a league which has been constituted with the purpose of fighting against the pest of tuberculosis. The council of administration of this league decided at one of its last meetings to establish a dispensary where people of any creed and nationality suffering from tuberculosis could receive medical treatment free of charge. It is intended to erect the charitable establishment with as little delay as possible and in a central position of the metropolis. It will be worked in the same manner and on the same principles as similar institutions existing in the western parts of Europe. The medical men belonging to the league will alternately attend the dispensary at certain fixed hours of the day. Treatment will also be accorded to patients suffering from any malady affecting the respiratory organs.

Medical Supervision of Servants.

The local newspapers announce that all domestics and servants will be submitted henceforward to a professional tax and to a medical examination. In case they prove to be free from any taint and satisfactory with regard to their family history they will receive a licence permitting them to enter in service. It is also stated that the municipal authorities have received the necessary injunctions to put into execution this new measure of safeguarding public interests.

Typhoid Fever.

Typhoid fever is raging in several suburbs of the metropolis. In Haskuyu alone, on the left bank of the Golden Horn, more than 90 cases have been reported in a comparatively short period of time. The number of deaths has not been stated definitely but it is supposed to be proportionately high. The sanitary authorities are naturally alarmed at this state of things and are taking the necessary measures of prevention. Rêshid Pasha, the prefect of Constantinople, has ordered that all the drains and fountains should be properly examined and the necessary repairs made.

Opium Smoking.

It has been found that the business quarter of Galata superabounds in localities where the habit of opium smoking is indulged in by many people in a rather alarming manner. These localities remain open the whole night and frequently serve as gathering places of all sorts of obscure and dangerous individuals. The police authorities have received strict commands to shut up these places and to prosecute their proprietors.

The Maternity Section of the Italian Hospital.

The Italian Hospital of Constantinople has opened a maternity section for the poorer classes of the population, under the charge of Dr. Scavridis. On Tuesday, Wednesday, and Friday mornings there will be a gratuitous out-patient consultation when pregnant women will be examined by midwives and the medical man in charge. Each of these pregnant women, if desiring to enter the maternity clinique at the approaching term of pregnancy, will have to write

down her name in the register kept at the hospital for that purpose and to occupy the bed assigned to her. If a woman wishes to be delivered in her own home she will be furnished with information and assistance. The rooms of the section are equipped with every requirement of modern hygiene and antiseptics and the departure should prove a veritable boon to indigent mothers.

March 8th.

Medical News.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—At a meeting of the Council of the above College held on March 14th the diploma of Fellow was conferred upon the following gentlemen who have previously passed the requisite examinations and have now complied with the by-laws of the College:—

Lionel Edward Close Norbury, M.B., B.S. Lond., M.R.C.S., L.R.C.P., St. Thomas's Hospital; and Gerald Charles Frederick Robinson, M.R.C.S., L.R.C.P., Guy's Hospital.

The diploma of Member was granted to—

Henry Orton Howitt, M.D., O.M. McGill University, McGill University and London Hospital.

A licence to practise Dental Surgery was issued to—

Thornton John Barnett, Charing Cross and Royal Dental Hospitals.

UNIVERSITY OF OXFORD.—Election of Chancellor: In a convocation held on March 14th the Right Hon. George Nathaniel, Lord Curzon of Kedleston, M.A., Hon. D.C.L., All Souls' College, was elected Chancellor of the University.—Degree of D.M.:—In a congregation held on March 14th the following degree in medicine was conferred: Doctor of Medicine, J. Freeman, University College. A scholarship in Natural Science is announced for competition on July 2nd at Brasenose College. Degree days:—The degree days for next term are the following: Thursday, May 2nd, at 10 A.M.; Saturday, May 25th, at 2.30 P.M.; Thursday, June 20th, at 10 A.M.; Thursday, June 27th, at 10 A.M.; and Saturday, July 6th, at 10 A.M.—Official Fellowship in Natural Science at Jesus College: The Principal and Fellows will shortly proceed to elect to an official Fellowship, to be held in conjunction with an assistant tutorship in natural science. The Fellow so appointed will be expected to teach one of the larger subjects recognised in the honour school of natural science, to undertake the entire direction of the science tuition of the college and generally to superintend the college laboratory now in course of erection; this, when completed, will be adapted for the teaching of chemistry and physics. He must be a graduate of some university within the United Kingdom and must be unmarried. His duties will commence at the beginning of the October term. He will be required to reside in college during full term. The emoluments will be those of an official fellowship, together with such a sum from the tuition fund as the college may from time to time determine, the whole stipend being not less than £450 per annum, together with the free use of rooms in college, and the usual allowances. Application of rooms in college, and the usual allowances. Application, together with a statement of the candidate's qualifications and experience, and such testimonials as he may desire to submit, should be sent, not later than May 1st next, by letter, to the Principal, Jesus College, from whom further details, including the conditions of tenure of an official fellowship, may be obtained. All letters addressed to the Principal on this subject should bear the words "Science Fellowship" upon the envelope.—On Thursday, March 14th, Dr. Charles Theodore Williams lectured before the Oxford Medical School on Laennec and the Discovery of Auscultation. He showed a remarkable series of stethoscopes; among the most interesting was one of the original forms devised by Laennec, and, indeed, made by Laennec himself, which was given to the lecturer's father, Dr. C. J. B. Williams. A large collection of the different forms of single stethoscopes were shown and a double stethoscope made by Dr. C. J. B. Williams in 1829 probably represents the first attempt of this kind. The ear-piece consisted of flexible metal. The advantages of the double stethoscope were discussed and a large number of different patterns were shown, including the demonstration stethoscope with which ten or 12 men can listen at once to a patient's heart or lungs. An interesting sketch was given of the life of Laennec and the various French and English editions of his work were exhibited.—Dr. C. Theodore

Williams has founded a scholarship in medicine of the value of £100 at his old college, Pembroke.

COLONIAL MEDICAL OFFICERS.—Mr. G. B. Mason, medical officer of Nevis, West Indies, has been promoted medical officer and magistrate of the Windward district of the Island of Dominica. Dr. F. G. Hopkins, senior medical officer of Southern Nigeria, has been promoted deputy-principal medical officer, and Mr. E. H. Read, medical officer, has become senior medical officer.

THE MEDICAL GOLFING SOCIETY.—The Medical Golf Tournament will take place on Thursday, May 30th, and application has been made to the Barnham Beeches Golf Club for permission to play off the event on its links. To secure the continuity from year to year of this popular fixture and to promote the interest of golf among medical practitioners there has been founded the Medical Golfing Society, with an annual subscription of 4s., the payment of this sum including entrance to the tournament. Any person on the Medical or Dental Registers can join by sending 4s. to the honorary treasurer, Medical Golfing Society, 1, New Cavendish Mansions, New Cavendish-street, London, W., and there seems no reason why the new society should not be as much of a success as the similar institutions supported by the Bar and the Stock Exchange.

The old-established medical publisher Mr. H. K. Lewis has just completed an important extension of premises at 126, Gower-street by the inclusion of 24, Gower-place adjoining. The two shops have been made into one, the older portion being utilised chiefly as the second-hand department. The library is entered from the end of the shop. Subscribers will be able to examine the books on the shelves when making exchanges, and convenience for writing or making extracts will be provided, the idea being to make this department a reading room for subscribers. The telephone in this room is free for subscribers' use. Lavatory accommodation is also provided. The premises are, as is well known, within a minute's walk of the Metropolitan station, and the new Tube station at the junction of Tottenham Court-road, Euston-road, and Hampstead-road is quite near.

DONATIONS AND BEQUESTS.—By the will of the late Surgeon-General Richard Chapman Lofthouse the balance of his property, if not exceeding £3000, is to be divided equally between the Harrogate Bath Hospital, the Harrogate Convalescent Home, the Harrogate Cottage Hospital, and the Yorkshire Home for Incurables. If it shall amount to £4000, then £1000 are to go to the pension fund of Epsom College. (Should certain schemes mentioned in the will be not carried out he left £1500 to the pension fund of Epsom College and the balance (over £40,000) equally between the four Harrogate charities above named.—£250 have just been received by the special appeal committee of the Royal Waterloo Hospital, S.E., from Mr. Otto Beit, executor of his brother's (the late Mr. Alfred Beit) estate. Also a seventh donation of £100 from "A. B." and smaller sums from the following City Companies—viz., the Leathersellers, Carpenters, Armourers, and Braziers.

THE OXFORD EYE HOSPITAL.—The twentieth annual report of this institution for the year 1906 has just been issued and we are glad to see that the notes about the hospital staff and the record of the committee's thanks to the honorary surgeons are the second item in the report and are not relegated to three lines at the end as a sort of after-thought after the expression of the thanks of the committee to the people who send eggs, old clothes, picture postcards, and other gifts, for this, we regret to say, is the custom of many hospital and dispensary committees. The medical work of the hospital during the year 1906 was made all the more difficult by the serious illness of Mr. R. W. Doyne, and in the absence of Mr. F. Menteith Ogilvie the work of the hospital was carried on by Mr. P. E. H. Adams, the assistant surgeon, and by Mr. Donald Gunn, formerly surgeon to the Westminster Ophthalmic Hospital, who gave valuable help on out-patient days while the emergency lasted. The medical report shows that various alterations in the out-patient department have been carried out, so that it is possible to do more work, and that better than before. The total number of attendances during the past year was 8483. The number of operations performed has slightly increased, but the number of eyes which have had to be excised is less than usual. Mr. Adams attributes this improvement chiefly to the fact that

people are abandoning home treatment and attend the hospital before the eye is irretrievably damaged. Certain research work has been done at the hospital and the annual post-graduate course, which is held in July, was well attended by medical men. Altogether the institution, which is the only fully-equipped hospital devoted to the treatment of injuries and diseases of the eye between London on one side and Birmingham on the other, seems to be doing excellent work; tickets of admission are not necessary, the sole passport being inability to pay for private treatment. The member of the committee acting as a visitor for the week makes the inquiries necessary for ascertaining the eligibility of applicants for admission into the hospital or for treatment as out-patients.

THE LATE DR. ADAM JAMESON.—Dr. A. Jameson, who recently was killed, at the age of 46 years, in a railway accident to the Delagoa Bay train while on his way home after retiring from the post of Commissioner of Lands in the Transvaal, was educated at Edinburgh and took the M.B. and C.M. degrees of the University of that city in 1883. The subject of his thesis for the M.D. degree, which he obtained in 1897, was "Malarial Fever." Later he went to Australia, where he practised for a few years and afterwards entered the Legislative Council of the colony and became Minister for Lands and the official leader of the Council. Subsequently he went to South Africa and in 1903 was appointed Commissioner of Lands in the Transvaal. He was a member of the Executive and Legislative Council at Pretoria.

RUSSIAN FACTORIES AND MEDICAL AID.—Under the heading of "Medical Aid to Workpeople in the Factories of the Mining and Metallurgical Industries" the *Finansk* *Finanss* observes that according to statistics published by the Mining Department there were in the year 1904 in European Russia and the Caucasus 3833 mining concerns, with a total of 426,334 workpeople. In these factories there were 214 hospitals with 4244 beds and 355 apartments. The cost of installing the hospitals, the apartments, and the ambulances was 5,482,972 roubles, and the annual expenditure on medical aid was 2,868,275 roubles, or an average of 6.72 roubles per head. In Asiatic Russia in the same year there were 650 mining works with a total of 54,744 workpeople. In these factories there were 127 hospitals with 1025 beds and 171 apartments. These cost (hospitals, apartments, and ambulances) 412,566 roubles, and the annual expenditure on medical aid was 445,337 roubles, or 8.13 roubles per head of the workpeople.

SOCIETY OF MEMBERS OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.—On March 14th a deputation from this society was received by the Lord President of the Council in reference to a memorial recently submitted to the Prime Minister, asking that some voice in the management of the College and its property might be given to the Members of the College. The deputation was introduced by Dr. V. H. Rutherford, M.P. Mr. Joseph Smith gave a short account of the history of the College, drawing attention to the fact that Members had made this claim from time to time ever since the first Charter was granted in 1800. He pointed out that the undoubted corporate rights of the Members as such did not carry with them as they should do any vote in the election of the Council or governing body. He referred to the fact of there being some 17,000 Members thus excluded, as against 1300 Fellows who alone have a vote at present. He also showed that a very large proportion of the income of the College is derived from the Members' fees. The Lord President inquired whether, apart from their general claim for representation, the deputation made any specific charges against the present governing body. Dr. W. G. Dickinson stated that no accusation of gross mismanagement was made against the Council, though they naturally considered that the management could be improved in various ways. The Lord President, in reply, said that he had listened with interest to the statements which had been made respecting the position of the Members, and he thought that the deputation had stated their case, on the whole, with great moderation. He agreed that it was anomalous that the representation in the College should be so limited. He would give the matter his closest attention and would endeavour, so far as possible, to act as a mediator in smoothing over the differences which had arisen between the Council and the Members. The deputation would not expect him to say more than this at present and he would probably have to ascertain the views of the

Council of the College in greater fulness. The deputation then thanked his lordship and withdrew.

At the first meeting of the new Pembroke-shire county council held on March 15th Mr. George Griffith, J.P., M.R.O.P. Edin., M.R.O.S. Eng., was unanimously elected chairman.

LONGEVITY.—The *Times* of March 18th states that on the previous day Mrs. Wenham, of Stramshall, the Park, Highgate, in North London, celebrated the 102nd anniversary of her birth. Mrs. Wenham enjoys good health and frequently takes a carriage drive.

ROYAL SEA-BATHING HOSPITAL, MARGATE.—The Earl of Derby presided at the annual court of governors of the Royal Sea-Bathing Hospital on March 13th and in moving the adoption of the report remarked that it contained in a condensed form a great deal of useful matter and showed that the institution was making steady progress. The necessity of early treatment of surgical tuberculosis in suitable surroundings did not yet appear to be realised sufficiently by the public and doubtless many cripples could have been prevented from becoming so had they applied for treatment at the Royal Sea-Bathing Hospital when they were first attacked by the disease. With regard to the proposed building of four new wards over the Wilson Wing, his lordship remarked that until this was done the hospital could not be said to meet modern requirements; the construction of these wards would set free certain old wards for accessory purposes not formerly contemplated, but which were now positively necessary in a modern up-to-date hospital. Lord Biddulph, treasurer, and Sir Henry Lennard, Bart., chairman of the committee of management, spoke of the need for better day rooms, a better dispensary, and a larger electrical department. Mr. Stuart Sankey, L.C.O., seconded the adoption of the report and referred to the fact that £3478 were received as patients' payments and trusted that this sum might be provided by increased public support and the patients treated free.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

Nurses' Registration Bill.

Mr. MUNRO FERGUSON has presented a Bill to regulate the qualifications of trained nurses and to provide for their registration. It has been read a first time and receives support from Members amongst all parties in the House of Commons. Its backers include Sir JOHN DICKSON-POYNTER, Mr. ROSE, Mr. RALPH, Mr. EYE, Mr. FELL, Mr. CROOKS, Sir GEORGE ROBERTSON, Dr. V. H. RUTHERFORD, Mr. JOWETT, and Mr. McKILLIP. The Nurses' Registration Bill provides for the appointment of a council to regulate the admission to the register of persons trained as nurses. During the two years following the passing of the Bill into law, any person who claims to be certified as a trained nurse shall be so certified provided such person is at least 21 years of age and (1) holds a three years' certificate of training from a general hospital or Poor-law infirmary approved by the council, and is of good character; or (2) produces evidence of training satisfactory to the same authorities and has in addition been for at least three years in *bond fide* practice as a nurse and is of good character. At the expiration of two years after the passing of the Bill any nurse claiming to be certified under it shall have completed a three years' term of training in the wards of a hospital or Poor-law infirmary approved of by the council and shall verify his or her qualifications for being so certified by such means as the council may prescribe.

Afflicted Children in Ireland.

A Bill has been presented in the House of Commons by Mr. CHARLES CRAIG to provide for the better education of afflicted children in Ireland. It was read a first time.

The Relief of Discharged Invalid Prisoners.

A Bill designed to make better provision as to the relief of persons released from detention in prisons, reformatory and industrial schools, and inebriate reformatories has been presented in the House of Commons by Mr. HERBERT SAMUEL, the Under Secretary for the Home Department, and the measure is backed by Mr. GLADSTONE. At present an administrative difficulty frequently arises when a person who is due for discharge from a prison is destitute and in such an infirm state of health as to require immediate Poor-law relief. It is the duty of the governor of the prison to see that the invalid shall receive proper care on his discharge. Where the place of settlement can be ascertained an order for the admission of the discharged prisoner to the workhouse of the union can be applied for. However, in practice it

has been found that frequently the place of settlement cannot be ascertained or that it is disputed. The only course in this case at present is to take the discharged prisoner to the workhouse of the union in which the prison is situated, but this, in the case of a large prison, imposes an appreciable liability on the ratepayers of the district in which it is situated. The Bill, which is officially entitled the Released Persons (Poor-law Relief) Bill, proposes to remedy the evil by following the precedent of the Criminal Lunatic Act, 1824. It throws the *prima facie* liability for the relief of an invalid prisoner whose place of settlement is unknown on the union in which he ordinarily resided at the time he committed the offence for which he was sent to prison, or, if that cannot be ascertained, on the union where the offence was committed. The guardians of the union to which he is sent in the first instance will be able afterwards, if they see fit, to take steps for his removal to his place of settlement. The same difficulty has been experienced in dealing with invalid persons discharged from reformatory and industrial schools and inebriate reformatories. The Bill proposes to follow the same procedure in dealing with these persons as with discharged prisoners.

Dental Companies (Restrictions of Practice) Bill.

LORD HYLTON has introduced into the House of Lords a Bill to prohibit joint-stock companies from carrying on practice as dentists or dental surgeons except by means of duly qualified persons. The Bill has been read a first time. Lord HYLTON explains the provisions of the existing law and the alterations which he proposes to make in it, in the course of a memorandum attached to his Bill. The memorandum sets forth that in many cases companies under the existing law have been formed by persons who have no qualifications entitling them under the Dentists Act, 1878, to practise dentistry and dental surgery, and these companies are carrying on dental practice by means of unqualified persons or assistants. The provisions of the Dentists Act, 1878, for the protection of the public against unqualified and ignorant practitioners, are thus systematically evaded. The effect of the Bill is to declare it unlawful for a company to practise dentistry or dental surgery, except by means of managers, assistants, or other persons, each of whom is duly qualified to practise dentistry and dental surgery by registration under the Dentists Act, 1878. The Bill further declares that whatever would be an offence under the Dentists Act when committed by an individual person shall also be an offence when committed by a number of persons formed and incorporated into a company. The Bill applies only to the carrying on by limited companies (including joint-stock companies and companies limited by guarantee) of the professional practice of dentistry and dental surgery. It does not apply to the carrying on of the purely mechanical business of the manufacture, sale, and repair of dental appliances. The Bill has the support of the General Medical Council. Enactments to the same effect have already become law in various parts of the British dominions.

Prohibition of Medical Practice by Companies Bill.

A Bill entitled the Prohibition of Medical Practice by Companies Bill has been introduced into the House of Lords by Lord HYLTON. Its object is to prohibit persons who are not by examination and registration legally qualified to practise medicine and surgery from carrying on business as medical practitioners by means of companies formed under the Joint Stock Companies Acts, under shelter of which they are able to evade liabilities attaching to them as individuals. By the Medical Acts penalties are imposed on an unqualified person who falsely assumes the designation of a legally qualified medical practitioner. Lord HYLTON, in an explanatory memorandum to his Bill, states that it has been ascertained that for some time past unqualified persons have had recourse to the machinery established by the Companies Acts, to enable them to carry on medical practice by forming companies for that purpose, and that companies so formed have been, and are, carrying on medical practice on a very large scale, especially among the poorer classes. The provisions of the existing law have been found insufficient to put a stop to such practices. It has even been possible under the existing law for a medical practitioner, whose name has by direction of the General Medical Council been erased from the Medical Register for crime or misconduct, to evade the consequences of the Council's judgment by forming a company under cover of which the practitioner may continue to practise as if he were still duly qualified. The Bill accordingly declares that whatever would be an offence under the Medical Acts when committed by an individual person shall also be an offence when committed by a number of persons formed and incorporated into a company.

LORD HYLTON further states in his memorandum that the effect of the Bill is to make it unlawful for a company formed under the Companies Acts (which includes a joint stock company or a company limited by guarantee) to practise as, or to carry on the business or profession of, a physician, surgeon, or medical practitioner. The Bill applies to existing companies but does not apply to companies formed to carry on business as manufacturers or sellers of medical, surgical, or dental appliances or preparations, pharmaceutical chemists, or chemists and druggists. Nothing in the Bill will prevent a limited liability company from carrying on convalescent homes, hydropathic establishments, and other institutions, of which the primary object is not the actual conduct of medical practice by unqualified persons; or will interfere with friendly

and other societies established for affording mutual relief in sickness and old age, or for assisting their members to obtain the services of duly qualified medical practitioners. The Bill has the support of the General Medical Council. enactments to the same effect have already become law in various parts of the British Dominions.

The Education Acts (Amendment) Bill.

The Education Acts (Amendment) Bill, which contains provisions as to the medical inspection of elementary school children, has passed through its committee stage, and been reported to the House of Commons.

HOUSE OF COMMONS.

WEDNESDAY, MARCH 13TH.

Municipal Milk Depots.

SIR FREDERICK BAYBURN asked the President of the Local Government Board whether he proposed to introduce legislation dealing with municipal milk depots.—MR. JOHN BRYS replied (in a written answer): Yes, I propose to do so.

THURSDAY, MARCH 14TH.

The Standardisation of Disinfectants.

MR. REES asked the President of the Local Government Board whether, in view of the prevalence of the sale of disinfectants which did not disinfect, he proposed to take any steps towards the standardisation of disinfectants.—MR. BRYS answered: I am not empowered to fix standards of disinfectants and it does not appear to me that I could usefully take action in the matter.

The Feeble-minded and Illegitimacy.

MR. WEDGWOOD asked the President of the Local Government Board whether he would cause registers to be kept by the medical officers of all workhouses and inmates of feeble-minded females who were delivered therein of illegitimate children, and whether he would lay upon the table, or otherwise publish, an annual summary of such registers.—MR. BRYS answered: I will take note of the suggestion of my honourable friend, but I think it will be desirable to defer any action in the matter pending the report of the Royal Commission on the Feeble-minded. I understand that the Commissioners are now engaged on their report.

What is Whisky?

MR. H. C. LEE asked the President of the Local Government Board what steps had been taken by his department to appoint a committee to inquire into and settle the question of what was whisky, having in view the postponement of the appeal against Mr. Fortham's decision.—MR. BRYS said, in reply: It appeared to me to be desirable that before I determined to take action of the kind referred to in the question the decision of the court of quarter sessions on a re-hearing of the appeal should be given, and I expressed an opinion to this effect. Further representations have, however, recently been made to me on the subject and these are now receiving my consideration. I may add that any committee appointed by me could only inquire into the matter. It would have no power to settle it.

Insanitary Conditions in St. Pancras.

MR. LEE asked the President of the Local Government Board whether he had yet received a report from the medical officer of health of the borough of St. Pancras on the insanitary condition of Little Clarendon-street, Somers Town, which report he stated that he had called for; also, what action, if any, had been taken by the borough council to deal with this insanitary property under the Housing of the Working Classes Act, 1890 to 1903, and if no action had been taken either by the borough council referred to or the Local Government Board, whether he would explain the cause of the delay.—MR. BRYS replied: I have received the report referred to. It shows that the houses in question are in fair structural condition and that no fault is to be found with the supply of light and air. Overcrowding, however, exists in the street, and a large number of notices for its abatement are served from time to time. The case appears to be one for action under the Public Health (London) Act, 1891, rather than under the Housing of the Working Classes Act, and I gather that the borough council is exercising its powers under the former Act.

Workmen's Compensation Act.

In reply to MR. BRACE, MR. GLADSTONE said: All cases where the accident happens after July 1st, 1907, will be under the new Workmen's Compensation Act. All cases where the accident happens before July 1st, 1907, will be under the old Act, except with respect to references to medical referees as to which the new provisions will apply.

Lunacy in Egypt.

DR. V. H. RUTHERFORD addressed a series of questions to the Secretary of State for Foreign Affairs regarding the allegation in the report of the director-general of the Egyptian lunatic asylum for 1906, that many dangerous lunatics had to be discharged uncurable owing to insufficiency of accommodation and also regarding the promised introduction of a lunacy law.—SIR EDWARD GREY in each case referred the honourable Member to Lord Cromer's report for 1906, which would shortly be published.

Water-supply of Ardler, Perthshire.

In reply to MR. WILKIE, MR. SINCLAIR said: My attention has been called to the unsatisfactory state of the water supply of the village of Ardler (Perthshire). The county medical officer has reported that in the autumn of 1906 a number of children in Ardler and other parts of the county suffered from "broken-out faces" but that there was no reason to connect these with the water-supply. The Local Government Board is in communication with the local authority with a view to an improved supply.

MR. LUTHER: Will the right honourable gentleman inquire whether the breaking-out of the faces of the children is, or is not, due to vaccination?—No reply was given.

MONDAY, MARCH 18TH.

Dr. Duncan's Dismissal.

MR. CATCHELAT WASON asked the Secretary for Scotland whether his

attention had been directed to the facts of Dr. G. Duncan's dismissal; that the reason given—viz., the refusal of Dr. Duncan to implement the agreement entered into by him with the parish council was incorrect; and that Dr. Duncan had been and was ready to carry out any arrangement or agreement entered into by him with the parish council; and if it was possible for him to take any action with the view of checking any injustice.—MR. SINCLAIR said in reply: I understand that the statement made in reply to my honourable friend's question of Feb. 25th, that Dr. Duncan failed to implement an agreement made with him three years ago to appoint an assistant, is correct, and that his recent offer to carry out this arrangement was held by the parish councils employing him to have come too late.

The Medical Inspection of School Children.

MR. JOWETT asked the President of the Board of Education what would be the probable cost of medical inspection under the Education (Administrative Provisions) Bill; and whether the grant would be in any way influenced by such inspection as was carried out by local education committees.—MR. MCKENZIE replied by written answer: I have no information as to the probable cost of medical inspection. The grants, other than those governed by statutes, are paid in respect of the efficiency of instruction and are not affected by any efforts which local education authorities may make in other directions.

MR. JOWETT further asked the President of the Board of Education whether he would state what expert staff it was proposed to provide at the Board of Education to advise as to amending arrangements under Clause 10 (b) of the Education (Administrative Provisions) Bill; and would there be any machinery, by inspection or otherwise, for standardising or insuring efficiency in the medical measures carried out by the local authorities and for reporting to the Minister for Education on the valuable scientific materials of educational value likely to become available.—MR. MCKENZIE answered: I think it would be premature at this stage to decide what machinery will be required by the Board of Education on the Education (Administrative Provisions) Bill becoming law, but the matter is having my careful consideration and the honourable Member's suggestions will not be lost sight of.

Rural Medical Officers of Health.

SIR WALTER FOSTER asked the President of the Local Government Board whether his attention had been drawn to statements made by Local Government Board medical inspectors in reports by them, quoted in the report from the Select Committee on the Housing of the Working Classes Act Amendment Bill, to the effect that certain medical officers of health and inspectors of nuisances in rural districts were, in fact, receiving inadequate salaries; whether the Local Government Board had recommended the repayment of a moiety of the salaries by the county councils in these cases; and, if so, whether it had received the consideration of the Board that they were thereby placed in the position of giving their approval to salaries which had been stated by their inspectors to be inadequate for a proper discharge of the duties required of such officers.—MR. JOHN BRYS replied by written answer: It is only as regards some of the districts in question that inspectors have in their reports directly referred to the salaries of the sanitary officers as inadequate. In most of these cases the Local Government Board had, prior to the inspector's visit, refused or threatened to refuse to sanction the appointment of all or some of the officers concerned. The visit of the inspector has usually led to a more satisfactory arrangement being made than that which previously existed, so that the Board has been able to sanction the appointments with a view to repayment of half the salaries by the county council.

The Case of Dr. Haflinger.

SIR WILLIAM COLLINS asked the Secretary of State for India whether Dr. Haflinger now held any appointment under the Indian Government; whether the use of Dr. Haflinger's prophylactic against plague was now encouraged by the Government; and whether any further information had been obtained in regard to 19 fatal cases of tetanus at Mukawal consequent upon the use of Dr. Haflinger's prophylactic.—MR. MORLEY (by written answer) replied: Dr. Haflinger is in the permanent service of the Government of India and is at present on leave in this country. He holds no appointment in India, but the Government of India has offered him employment in that country on research work at a salary equal to that of which he was in receipt when he left India. Inoculation with Dr. Haflinger's prophylactic continues to be one of the precautions which are recommended by Government to the general population against outbreaks of plague, and facilities are provided for persons who wish to be inoculated. Papers containing the results of the inquiry into the origin of the accidental deaths from tetanus poisoning in the Punjab have recently been published by the Government of India. I have no objection to lay them if they are moved for.

WEDNESDAY, MARCH 20TH.

Parochial Medical Officers (Scotland) Bill.

MR. CATCHELAT WASON asked leave to bring in under the ten minutes' rule a Bill "to amend the law relating to the tenure of parochial medical officers of Scotland." He said that he would take the occasion to bring before the Government and the country a long-standing grievance of the medical profession in the Highlands and Islands of Scotland. The Poor-law medical officers in Scotland had, since the passing of the Local Government Act of 1894, found that their position had altered for the worse. A number of dismissals had taken place on petty grounds. Representations had been made on this point to successive Secretaries for Scotland, and from the reception accorded to a deputation last year he had no reason to believe that the present occupant of that office held any antagonistic view to the contention of the medical profession. It was a gross scandal and injustice that Poor-law medical officers in the north of Scotland had been dismissed on petty grounds. The Bill asked that these gentlemen should go to the Local Government Board for Scotland and have their case heard by it. The medical officers of poor houses in Scotland had had that right during the last five years and in consequence of it there had not been one application from them to the Local Government Board. To give Poor-law medical officers this right of appeal when they were threatened with dismissal would only be a small act of justice.

Leave having been given MR. WASON introduced his Bill which was read a first time.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to THE LANCET Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week such information for gratuitous publication.

BERGIN, FRANK GOWER, L.R.C.P., M.R.C.S., has been appointed House Surgeon at the Bristol General Hospital.
 BLACKETT, JAMES FRANCIS, M.B., B.S. Lond., has been appointed Assistant House Physician at the Bristol General Hospital.
 BRISCOE, WILLIAM THOMAS, M.D., M.Ch. Dub., has been appointed Medical Officer for the Pwsey District by the Chippenham (Wills) Board of Guardians.
 CAREY-EVANS, T. J., M.D. Brux., M.R.C.S., L.R.C.P. Lond., has been appointed House Surgeon at the Royal Southern Hospital, Liverpool.
 COLEMAN, F., M.R.C.S., L.R.C.P., L.D.S. Eng., has been appointed Assistant Dental Surgeon at St. Bartholomew's Hospital.
 COULSON, THOMAS EDMUND, M.B., Ch.B. Edin., has been appointed Senior House Surgeon at the Bristol General Infirmary.
 ELLIOTT, WILLIAM HAROLD ARTHUR, M.B., B.S. Lond., L.S.A., has been appointed Medical Officer to the Bristol Dispensary.
 HEWLETT, FRANK, M.B., P.R.C.S., has been appointed Honorary Surgeon with charge of the Ophthalmic Department at the St. Pancras and Northern Dispensary.
 HUGHES, EDWARD HYLIE HURST, L.R.C.P. & S. Edin., L.F.P.S. Glasg., has been appointed Resident Medical Officer at the Newport (Mon.) Workhouse.
 KINGSDOTE, ERNEST, M.B., C.M. Edin., has been appointed Honorary Physician to the St. Pancras and Northern Dispensary.
 MACKAY, ERNEST C., B.S., M.D. Lond., M.R.C.S., L.R.C.P. Lond., has been appointed Honorary Medical Officer to the Convalescent Home of the Chelsea Hospital for Women.
 MILLER, A. H., M.B., B.C. Cantab., has been appointed Resident Medical Officer to Out-patients at Queen Charlotte's Hospital.
 MORRIS, LEONARD NEWSON, L.R.C.P. Lond., M.R.C.S. Eng., has been appointed House Physician at the Bristol General Hospital.
 O'DONOVAN, T. J., L.R.C.P. & S. Edin., L.F.P.S. Glasg., has been appointed Certifying Surgeon under the Factory and Workshop Act for the Johnstown District of the county of Cork.
 PRINIGER, WILFRED J. H., M.B., B.S. Lond., L.R.C.P., M.R.C.S., has been appointed Casualty House Surgeon to the Bristol General Hospital.
 POWELL, HUGH, M.D., M.R.C.S., L.R.C.P. Lond., has been appointed Honorary Surgeon to the Cheltenham General Hospital Branch Dispensary and Assistant Obstetric Surgeon to the District Nursing Association.
 POWER, J. H., M.R.C.S., L.R.C.P. Lond., has been re-appointed Medical Officer to the Spalding Union Board of Guardians.
 TAYLOR, J. FRANCIS, M.R.C.S., D.P.H., has been appointed Medical Officer of Leyton.
 THOMPSON, THEODORE, M.D. Cantab., M.R.C.P. Lond., F.R.C.S. Eng., has been appointed Assistant Physician at the London Hospital.
 WADE, REGINALD, M.R.C.S., L.S.A., has been appointed Medical Officer of Health for the Highbridge (Somerset) Urban District.
 WILSON, MURRAY RICHARD OSMOND, L.R.C.P., M.R.C.S., has been appointed Casualty House Surgeon to the Bristol General Hospital.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

BIRMINGHAM UNIVERSITY OF.—Demonstratorship in Anatomy. Salary £150 per annum.
 BLACKBURN AND EAST LANCASHIRE INFIRMARY.—Senior House Surgeon and Junior House Surgeon. Salary £110 and £70 per annum respectively, with board, washing, &c.
 BODMIN, CORNWALL COUNTY ASYLUM.—Third Assistant Medical Officer, unmarried. Salary £140 a year, rising to £160, with rooms, rations, laundry, and attendance.
 BOURNEMOUTH, ROYAL BOURNEMOUTH AND WEST HANTS HOSPITAL.—House Surgeon for six months. Salary £20 per annum, with board, lodging, and washing.
 BRISTOL EYE HOSPITAL.—House Surgeon. Salary £20 per annum, with board and residence.
 CENTRAL LONDON OPHTHALMIC HOSPITAL, Gray's Inn-road, W.C.—Assistant Surgeon.
 CHELSEA HOSPITAL FOR WOMEN, Fulham-road, S.W.—Clinical Assistant.
 CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST, Victoria Park E.—House Physician for six months. Salary at rate of £50 per annum, with board and residence.
 COVENTRY AND WARWICKSHIRE HOSPITAL.—Junior House Surgeon for six months. Salary £50 per annum, with rooms, board, washing, and attendance.
 DEVONPORT, ROYAL ALBERT HOSPITAL.—Assistant Resident Medical Officer, unmarried, for six months. Salary at rate of £50 a year, with board, lodging, and laundry.
 BEVELLA HOSPITAL FOR SICK CHILDREN, Southwark, S.E.—Clinical Assistants for three months.
 EXETER, ROYAL DEVON AND EXETER HOSPITAL.—Assistant House Surgeon, unmarried. Salary £50 per annum, with board, lodging, and washing. Also House Surgeon. Salary £120 per annum, with board, apartments, and washing.
 HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Brompton.—Resident House Physicians for six months. Honorarium of £25.

Huddersfield Infirmary.—Senior Assistant and Junior Assistant House Surgeon. Salaries £60 and £50 respectively per annum with board, rooms, and washing.
 Ingham Infirmary and South Shields and Westoe Dispensary.—Assistant House Surgeon. Salary £75 per annum, with residence, board, and washing.
 LEEDS GENERAL INFIRMARY.—Resident Casualty Officer. Salary £125 per annum, with board, lodging, and washing.
 LEEDS PUBLIC DISPENSARY.—Two Junior Resident Medical Officers. Salary £100 per annum, with board and lodging.
 LEEK, STAFFORDSHIRE COUNTY ASYLUM, Cheddleton.—Junior Assistant Medical Officer. Salary £160 per annum, rising to £200, with board, quarters, and washing.
 LEICESTERSHIRE AND RUTLAND ASYLUM, Leicester.—Second Assistant Officer, unmarried. Salary £130, rising to £160, with apartments, board, and washing.
 MANCHESTER CHILDREN'S HOSPITAL, Pendlebury.—Assistant Medical Officer. Salary £100 per annum.
 METROPOLITAN LAB. NOSE, AND THROAT HOSPITAL, Grafton-street, Fitzroy-square, W.—Three Senior Clinical Assistants.
 NEWPORT AND MONMOUTHSHIRE HOSPITAL.—Junior Resident Medical Officer. Salary £70 per annum, with board, residence, and laundry.
 NOTTINGHAM CHILDREN'S HOSPITAL.—House Surgeon (female) for six months. Salary at rate of £30 per annum, with board, residence, and washing.
 RICHMOND, SURREY, ROYAL HOSPITAL.—Assistant House Surgeon. Salary £70 per annum, with board and apartments.
 ROYAL EAM HOSPITAL, Dean street, Soho, W.—House Surgeon, non-resident, for six months. Honorarium at rate of £40 per annum.
 ROYAL LONDON OPHTHALMIC HOSPITAL, City-road, E.C.—Refraction Assistant. Salary £25 a year, with lunch.
 ROYAL SOUTH LONDON DISPENSARY.—Honorary Surgeon-Dentist.
 SCARBOROUGH HOSPITAL AND DISPENSARY.—Junior House Surgeon. Salary £80 per annum, with board and residence.
 SEAMEN'S HOSPITAL SOCIETY, Greenwich, S.E.—For DREADNOUGHT HOSPITAL: Two House Physicians and Two House Surgeons. Salary in each case £50 per annum, with board, residence, and washing.—For BRANCH HOSPITAL, Royal Albert Dock, E.—Senior House Surgeon and Registrar, also House Surgeon. Salary of former £100 per annum, and of latter £50 per annum, with board, residence, and washing.
 SHEFFIELD UNION HOSPITAL.—Resident Medical Officer and Resident Assistant Medical Officer. Salary of former £100 per annum and of latter £80 per annum, with allowances, apartments, rations, &c., in each case.
 SOUTHAMPTON, ROYAL SOUTH HANTS AND SOUTHAMPTON HOSPITAL.—House Surgeon. Salary £100 per annum, with rooms, board, and washing. Also Junior House Surgeon for six months. Salary at rate of £60 per annum, with rooms, board, and washing.
 STAFFORD, STAFFORDSHIRE GENERAL INFIRMARY.—Assistant House Surgeon. Salary £32 per annum, with board, residence, and laundry.
 SUNDERLAND INFIRMARY.—House Surgeon. Salary £30 per annum, with board, residence, and washing.
 TOTTERHAM HOSPITAL, London, N.—Honorary Medical and Surgical Registrars.
 WEST BROMWICH DISTRICT HOSPITAL.—Resident Assistant House Surgeon, unmarried. Salary £50 per annum, with board, residence, and washing.
 WHITEHAVEN AND WEST CUMBERLAND INFIRMARY.—Resident House Surgeon. Salary £120 a year, with board and lodging.
 WOLVERHAMPTON AND STAFFORDSHIRE GENERAL HOSPITAL.—Senior House Surgeon. Salary £100 per annum, with board, lodging, and laundry. Also Second House Physician. Salary £80 per annum, with board, lodging, and laundry.
 WREXHAM INFIRMARY.—Resident Medical Officer. Salary £30 per annum, with board, lodging, and washing.

THE Chief Inspector of Factories, Home Office, S.W., gives notice of vacancies as Certifying Surgeons under the Factory and Workshop Act at Bourne, in the county of Lincoln; at Instidale, in the county of Kilkenny; and at Stanmore, in the county of Middlesex.

Births, Marriages, and Deaths.

BIRTHS.

MURIEL.—On March 15th, at Scotch-street, Whitehaven, the wife of G. Bertram Murriel, B.A., M.B., B.O. Cantab., M.R.C.S. Eng., L.R.C.P. Lond., of a daughter.
 PENNEFATHER.—On March 15th, at Deanhurst, Harrow, the wife of Claud Maxwell Pennefather, M.B., of a son.
 RICKETT.—On March 18th, at Sherborne, Dorset, the wife of Gerald R. Rickett, M.A., M.B. Cantab., of a son.

MARRIAGE.

BLGOOD.—Amos.—On March 7th, at All Saints' Church, Cairo, Percival George Blgood, Major, late Devonshire Regiment, to Boud Sheldon Amos, M.B.

DEATHS.

MCCONAGHEY.—On March 18th, at "Moorlands," Cyprus road, Exmouth, in his 58th year, Colonel John McConaghey, late of I.M.S. Indian papers please copy.
 PEARCE.—On March 7th, at Alfred-place, Plymouth, William Henry Pearce, M.D. Edin., aged 77 years.

£1.—A fee of 6s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

HOSPITAL ABUSE: AN ATTEMPTED REMEDY.

On March 12th the Newcastle-on-Tyne Central Dispensary for Diseases of the Nose, Throat, Eye, and Ear was opened. Diseases of the eye are treated on Tuesdays and Fridays at 9 A.M. and diseases of the nose, throat, and ear on Wednesdays and Thursdays at the same hour.

Patients are only seen subject to the following regulations:—

Special Regulations of the Central Dispensary.

- I. That no patient except urgent cases, such as accidents, be treated unless they bear a letter of recommendation.
- II. That urgent cases, such as accidents, will be seen on behalf of their ordinary medical attendant, who will therefore be entitled to charge his usual fee, and will not receive any after treatment unless they bear a letter of recommendation.
- III. That no letters of recommendation be accepted, except those from medical men, or the Charity Organisation Society.

These regulations are admirable and should go some way towards solving the question of hospital abuse. As regards No. II., however, we doubt whether if a patient refused to pay his ordinary medical man a fee for the treatment received at the dispensary the medical man could recover such fee by law. Of course, the after-treatment must be paid for if carried out by the medical man. Regulation No. III. is also much to be commended, for the average possessor of a hospital letter uses it in the most haphazard style, and is accustomed to get very angry if his or her nominee is refused as an unfit case. We congratulate the authorities of the dispensary upon their departure.

GAS POISONING.

To the Editors of THE LANCET.

SIRS,—Some time ago I read an article in THE LANCET condemning the sliding chandelier, which if neglected and not regularly supplied with water allows the gas to escape, resulting in gas poisoning and in many cases explosions. Until recently I was not aware of the general ignorance of servants in this matter. I have within the past few weeks questioned no less than six different servants of long experience in Dublin houses and they all, without exception, said that they never heard of the thing being necessary or done in houses where they were employed. Now, it is a remarkable fact how popular these sliding chandeliers are in Dublin houses, both with the rich and the poor, and if the chandeliers are not properly looked after it is lamentable to think what sickness must be caused by gas escaping. I hope you will give prominence to this letter in the hope of enlightening the public against the use of sliding chandeliers and the dangers of gas poisoning.

I am, Sirs, yours faithfully,

P. B. P.

Dublin, March 11th, 1907.

A CIRCUMSTANTIAL STORY.

Under the heading, "A Lady's Remarkable Experience," a newspaper published recently the following paragraph:—

"An extraordinary event occurred at Boston on Saturday week. A Miss Annie Wold, who resides with her mother, complained of a peculiar feeling in her chest. Shortly after partaking of a dinner consisting of boiled beef, carrots, and potatoes she lay down to rest, when she was seized with a choking sensation, and to her horror vomited a creature several inches in length of a dark yellow colour and with two bright eyes, and the hind part curled over the back in the form of a tail. The lizard—for such it was—has been preserved in spirit, and will be forwarded to the College of Surgeons. Several persons have seen it and Dr. Winch describes it as being about six inches or seven inches in length."

Note the circumstantiality of the story. The fearful beast is described with a minuteness that only a personal inspection could warrant, and the medical man is, apparently at any rate, quoted as acquiescing in the accuracy of the narrative. Dr. Winch has written to us as follows:—

"A patient of mine having previously complained of some slight throat trouble one day vomited up a thin membrane. She got it into her head that it was alive, and her neighbours were called in to see the 'thing,' when it was made out to be an animal of some description. The patient called me in three days after to look at it, and I at first thought it was a bronchial cast—anyhow I assured her that it was not alive. I said that I would have it examined microscopically. This was done, and the substance was reported by the Clinical Research Association to be a 'vegetable leaf in a partial state of digestion.' In the meantime the wonderful occurrence had been so talked about, I suppose, that it reached the ears of some reporter, for two or three days after the episode there appeared in a newspaper a paragraph in which I was quoted as saying that the animal was so many inches long."

We have come to the conclusion that there is nothing that the lay journal will not believe if only the occurrence lies outside the normal range of medicine. Within that range many newspapers will cheerfully contradict the commonplaces of science.

A CURIOUS MEDICAL ACCOUNT.

We have received from a medical correspondent an interesting little document in the shape of a bill for medical attendance on a well-to-do farmer and his family during a period of about ten years—namely, from 1842 to 1852. During this time, we understand, there were five births and three deaths in the family and several long attendances besides. The bill reads as follows: "Slaidburn, May, 1853. Mrs. Waterworth. To Visits, Medicine, and Attendance from 18th October, 1842, to 9th October, 1852, £6 8s. 6d.; by goods, £3 0s. 6d.; total due to Mr. Theodore D. Jackson, £3 8s. 0d." The bill bears at the bottom the intimation that particulars will be supplied if required and it was paid on May 29th, that is two days after it was received by the debtor. A curious feature of the bill is the item "By goods," which reminds us of the system of barter in existence at this comparatively recent period of time. Part of the payment was in kind and would probably consist of hay and other farm produce. No doubt the country medical man often receives payment in this way, but 50 years ago this primitive method of exchange was very usual.

FOR SEA-BIRDS.

To the Editors of THE LANCET.

SIRS,—The inclosed cutting from to-day's *Mirror* must surely touch bed-rock in the hunt for sea-birds:—

VARICOSE VEINS

are due to sluggish blood and weakened nerve force. When healthy, your blood and nerves are highly magnetic. When these great life centres lack magnetism you must be a prey to disease. Magnetic Leggings restore the missing force and thus cure you. Price: One Pair of Leggings, £1 1s. or 1s. 6d. deposit and seven instalments of 2s. 6d. Send measurement round calf and above ankle. Write for our valuable FREE BOOK on Magnetism. It shows how you can cure all diseases in your own home. THE INSTITUTE OF NATURAL THERAPEUTICS (Dept. D.M.), 73, Queen Victoria-street, E.C.

N.B.—Elastic Stockings wear out quickly and have never cured anyone.

The advertisement should appeal to all who have faith in mechanical wonders like the "Evans Vacuum Hair Raiser."

I am, Sirs, yours faithfully,

DOUGLAS J. MUNRO, B.S., M.B. Lond., &c.

Acre-lane, Brixton, S.W., March 14th, 1907.

A POST-CARD.

We have received the following unassigned post-card. When such evidences of credulity are forthcoming we can hardly wonder that the specious promises of quacks are widely believed:—

2/3.07.

SIR,—Seeing in to-day's paper that you have published a list of those who have killed themselves I would like to let you know I in *Daily Malta Chronicle* (address *Daily Malta Chronicle* Malta and 1d. stamp will find it) about October 1902 appeared an account of a successful experiment—or some stuff applied—which brought a strangled dog to life after being dead 8 hours and which the discoverer thinks would be equally efficacious if applied to human beings. If in *Daily Express* (a London Jd. daily) on 4th October 1902, and in *Lloyd's Budget* and *People* same week appeared an account of a successful experiment which brought cats, dogs, bees, flies, and I drowned boy (given up for dead by doctors) to life after hearts ceased beating. The subjects were asphyxiated and brought to life by being placed on a warm plate or cloth and entirely covered with the following powder after which life appeared:

Extract from Article.

"The doctor makes use in his experiment of a light salt solution saturated with oil of the body which is allowed to stand exposed in an atmosphere of free ammonia. From this solution a powder is derived and it is this powder which contains the life renewing properties."

Now Sir kindly tell immediately local authorities where fatalities took place information I re those who hanged themselves and I re those who were drowned or asphyxiated—in any cases which occurred during last 7 days—have above experiments tried immediately on bodies, saving perhaps valuable lives.

Yours &c.

THE "THERMASEP" CLINICAL CASE.

This is a metal case designed to keep the clinical thermometer in an aseptic condition. At one end of the case is a small chamber containing paraform. It is just above this space where the bulb of the thermometer rests. Paraform gives off formic aldehyde vapour. The "Thermasep" is supplied by Mr. W. Martindale of 10, New Cavendish-street, London, W.

WHAT IS PLASTICINE?

To the Editors of THE LANCET.

SIRS,—Can any of your correspondents tell me what "Plasticine," a modelling material, is made and coloured with? It has, I have found, caused a disease of the nails in a little girl who has been using it.

I am, Sirs, yours faithfully,

March 13th, 1907.

LONDON.

WANTED—A HOME.

A CORRESPONDENT, who is a senior student of medicine, but who for some eight years has been suffering from Graves's disease and whose sole worldly possession is a sum received from a benefit society of 6s. a week, is anxious to know whether there is any hospital or any home which will admit him free for two or three years. Professor Clifford Allbutt is acquainted with the case and considered in November, 1905, that our correspondent might recover if he were put under suitable conditions for acquiring rest in the open air. Perhaps some of our readers know of an institution such as is required.

FOODS FOR THE DIABETIC: A CORRECTION.

To the Editors of THE LANCET.

SIRS,—In your last issue appeared a paragraph mentioning Casold and Casold Meal diabetic breads in connexion with the name of another firm. As we are the only makers in the world of these two special diabetic breads, we shall be glad if you will be good enough to publish this correction. Thanking you in anticipation,

We are, yours obediently,

74, Regent-street, London, W., March 19th, 1907. CALLARD & Co.

THE "ANTISEPHONE."

THE "antiseophone" consists of a wax tube made in the shape of, but a little smaller than, the telephone receiver into which it fits and two small steel springs serve to keep it in position. The wax is impregnated with a volatile antiseptic oil so that it is assumed that this mouthpiece prevents infection. The use of a volatile antiseptic is, of course, clearly and may have some germicidal effect, but the evidence of bacteriological experiment seems to us to be required before it can be positively stated that the use of the "antiseophone" renders the telephone mouthpiece absolutely free from infective matters. The patentees and manufacturers are the Patent "Antiseophone" Co., Chapel Walks, South Castle-street, Liverpool.

THE HISTORY OF MEDICINE.

To the Editors of THE LANCET.

SIRS,—The following is possibly more important than any of those works mentioned in your reply to "W. H. B.": "Handbuch der Geschichte der Medizin," begründet von Th. Puschmann, herausgegeben von M. Neuburger und J. Pagel, 1902-05. Fischer, Jena. It is published in three large octavo volumes.

I am, Sirs, yours faithfully,

CUTHBERT E. A. CLAYTON,

Librarian, Manchester Medical Society.

March 15th, 1907.

Mr. B. B. Gough.—So far as we are aware, the only ground upon which a servant could claim against her employer in the circumstances suggested would be that of negligence. If he knowingly and recklessly exposed her to the danger of infection without her being aware that it existed, we should say that he might be held liable. Whether she would be likely to win her case would depend upon the evidence which she could bring to prove that her employer was negligent and that his negligence caused her condition.

M.R.C.S., L.R.O.P.—The preparation in question may give relief in some cases, but it should never be used by anyone except under strict medical supervision, for it contains cocaine and atropine. The preparation is sold under the usual conditions of pretence and extortion prevalent in American quackery.

Mr. E. E. Norris.—Yes, the person in question is a quack. We advise our correspondent to have nothing to do with him or his "remedies."

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

METEOROLOGICAL READINGS.

(Taken daily at 8.30 a.m. by Stewart's Instruments.)

EDITORIAL NOTICES.

It is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on *one side of the paper only*, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET should be addressed "To the Manager."

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

The Index and Title-page to Vol. II. of 1906, which was completed with the issue of Dec. 29th, were given in THE LANCET of Jan. 5th, 1907.

VOLUMES AND CASES.

VOLUMES for the second half of the year 1906 are now ready. Bound in cloth, gilt lettered, price 18s., carriage extra.

Cases for binding the half year's numbers are also ready. Cloth, gilt lettered, price 2s., by post 2s. 3d.

To be obtained on application to the Manager, accompanied by remittance.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will insure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	 £1 12 6	One Year	 £1 14 8
Six Months	 0 18 3	Six Months	 0 17 4
Three Months	 0 8 2	Three Months	 0 8 8

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates, on this or on any other ground, should be resisted. The Proprietors of THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues; and Agents are authorised to collect, and generally do so collect, from the Proprietors the cost of such extra postage.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied. Address—THE MANAGER, THE LANCET OFFICES, 423, STRAND, LONDON, ENGLAND.

Communications, Letters, &c., have been received from—

A.—Dr. John Allan, Edinburgh; Mr. B. Arnold, Lond.; Messrs. B. Arber and Co., Malvern; Automobile Press Agency, Lond.; Arlosco Co., Lond.; *American Journal of Surgery*, New York, Managing Editor of; Association for Promoting the Training of Midwives, Lond.; Secretary of; Dr. J. Subscriptions (which may commence at any time) are payable in advance.

An original and novel feature of "THE LANCET General Advertiser" is a Special Index to Advertisements on pages 2 and 4, which not only affords a ready means of finding any notice but is in itself an additional advertisement.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Answers are now received at this Office, by special arrangement, to advertisements appearing in THE LANCET.

The Manager cannot hold himself responsible for the return of testimonials, &c., sent to the Office in reply to Advertisements; copies only should be forwarded.

Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Office, 423, Strand, London, to whom all letters relating to Advertisements or Subscriptions should be addressed.

THE LANCET can be obtained at all Messrs. W. H. Smith and Son's and other Railway Bookstalls throughout the United Kingdom. Advertisements are also received by them and all other Advertising Agents.

Agent for the Advertisement Department in France.—J. ASTIER, 31, Rue Baptis, Asnières Paris.

The Lumleian Lectures

ON

THE INCREASE OF INSANITY.

*Delivered before the Royal College of Physicians of London on
March 14th, 19th, and 21st,*

By G. H. SAVAGE, M.D. LOND.,
F.R.C.P. LOND.,

CONSULTING PHYSICIAN FOR, AND LATE LECTURER ON, MENTAL
DISEASES, GUY'S HOSPITAL; CONSULTING PHYSICIAN TO
THE IDIOT ASYLUM, EARLEWOOD.

LECTURE I.

Delivered on March 14th.

MR. PRESIDENT, FELLOWS, AND GENTLEMEN,—I have little doubt that each of my predecessors has in turn experienced a certain apprehension before he has delivered, with due imperturbability, the Lumleian lectures. In my own case the feeling of pride at the honour bestowed on me by the selection of our President was immediately succeeded by some uncertainty as to the precise subject which I should select, and the apprehension still persists lest I should in any way fail in my duty or fall short of my responsibility to you. Wishing to do my best I have naturally selected the subject which my special experience of 40 years should enable me to treat with some authority. But as I have not thought it desirable on this occasion to hazard any new theory or treat any special point with all the detail of thought and illustration which it would undoubtedly require, I trust that the apparently somewhat discursive nature of my remarks upon the wider issues may be attributed to a desire to lay before you facts which are of general rather than highly particularised significance. At the present time the subject of the increase of insanity is being very carefully considered, not only in England but in all civilised countries, and I feel that the very fact that it is being so considered has increased my difficulty. In all directions, both in the medical and lay press, articles have appeared on the subject, so that I have little doubt that the opinions which are the result of my own experience will frequently be found to coincide with the opinions already expressed by other observers. At the outset I must acknowledge my own definite conviction that there is a steady increase in the numbers of the insane, and that this increase shows a definite relationship to the progress of civilisation. I do not myself think that this estimation necessarily implies the hopeless degeneration of the race, nor do I think that it furnishes an authentic basis for dread as to the future of the minds and bodies of our successors. With the multiplication of rules and regulations it becomes more and more difficult to characterise individual groups, but my own particular experience seems to indicate that many cases are attributable rather to social misfits than to material brain disease. In describing these and similar cases I may say that I rely upon my own observation supported by such statistics drawn from official sources as I may find it necessary to employ in connexion with the more recognised groups.

Let me, however, indicate the lines on which I propose to move. First of all, before studying the question of the increase of insanity it is essential that we should recognise what we mean by insanity. Of course, I take primarily the medical standpoint, but I have my doubts as to whether the social one is not, after all, the more practically important of the two. We find ample evidence that with no merely medical opinion on unsoundness of mind is the public easily satisfied; no doubt it would often be much better if it were. Next I will examine briefly into the more generally accepted causes and endeavour to show if it is possible to find amongst them any indication of the actual lines of increase. So that in a word the question will be, What are the special forms of insanity which are increasing? What are the causes which are more in evidence than they formerly were? And what hitherto unrecognised moral or physical causes are tending to produce, or to reproduce, mental unsoundness? And the evidence which I can offer in reply to these questions will, I hope, enable you to form conclusions as to the validity of the reasons given for the increase of the certified or uncertified insane.

To begin with, in judging the conduct of any person supposed to be of unsound mind it must be recognised that No. 4361.

similar conduct may arise from totally different disorders or circumstances and also that the mind is a very complex thing which has many ways of expressing the same feeling. Take, for example, the exaltation of ideas in a patient believing himself to be a king or a person of distinction. Such an idea may correspond with a temporary increase of pulse rate and I have seen it prominent or suppressed as the pulse varied. It may succeed to the loss of judgment as a feeling of buoyancy in general paralysis of the insane; it may be associated with the temporary disorder produced by brain-poisoning—say by lead or alcohol; or it may be a slow growth in some "mute inglorious Milton" or lonely idealist, who, possibly building on the "might have been," finally recognises in himself or herself a scion of royalty or an inspired poet. Or again, perhaps in a more advanced stage of degeneration of tissue the patient may have begun by feeling that he was watched or spied upon, until at length he discovered that all this was merely the protection essential to the movements of a royal personage—himself. In each case the conduct of the patient is similar, though the underlying ideas are so different. Similarly, I have often had to point out that what might be a reasonable act in one person would be insane extravagance in another. I mention these facts here because in determining what is meant by insanity or what is to be done for it the circumstances and environment have always to be considered. And notwithstanding their mutual points of resemblance, no one pathology or treatment is applicable to all such cases.

A question which I am often asked is whether I believe that certain persons only can be driven insane, whether the rest can never be driven mad—whether in regard to these latter anything whatever in the shape of exciting cause will produce definite symptoms without the insane proclivity. My reply is that almost anyone may have delirium, which is temporary insanity; that almost anyone given certain physical causes may have general paralysis. Also, as is sufficiently evident, that with advancing years the powers of the mind, both on the motor and sensory sides, may be impaired or disabled before the other functions of the body. Yet this notwithstanding I still believe there are some persons who can hardly be driven mad by any outside stress or emotional cause. And surely it is worthy of consideration that so many very aged persons retain their senses and reasoning power almost unimpaired until the very last. On the other hand, that there is a class of persons accurately described as "neurotic" is very evident; and it is equally certain that it is this class which provides the largest number of sufferers from insanity and allied disorders. It is in regard to these that I have stated my belief that there is no ground for supposing the increase to be of an alarming extent.

But it may be well here to consider what I mean by "neurotic," for I find it regarded as such a convenient term that it has frequently been made to include almost any nervous or mental disorder not showing very marked symptoms. To be civilised, as a sane person, implies the capability of reacting normally to the changing conditions of one's surroundings, so as to interfere as little as possible with the interests, safety, and welfare of other persons living under similar conditions. With increasing complexity there must be an increasing power of adaptation, and, as might be expected, this will often be found associated with a deficient or an undue mobility. It is in this abnormality of reaction to surroundings that we find the true empirical basis of neurosis. Now this may arise from many diverse conditions. It may be a result of weak, degenerating, or insane parentage, or it may arise from causes which materially interfere with the nutrition of the higher nervous organs, from toxic influences, for example, or from generally debilitating causes, such as excesses of any kind. The point to consider is whether any of these influences have been acting so forcibly as to render the civilised races at the present time more likely to break down along nervous lines. In regard to this tendency the reports of the Commissioners in Lunacy for England, Scotland, and Ireland will be found most instructive. We are fortunate in this respect that the Irish Commissioners last year, taking it for granted that there was an increase in the numbers of the insane, addressed special inquiries to the various medical officers of the asylums on this point and elicited their individual opinions in regard to it. Special stress, I may remark incidentally, was laid upon the danger of hereditary predisposition and excessive indulgence in alcohol. I think, therefore, that conclusions based on these reports, in so far as they agree, may be taken

as the composite opinion of asylum physicians as to the causes of any such increase.

And now to speak a little more definitely on my first point: I still believe that what Hughlings Jackson said many years ago is true—viz., that we physicians connected with insanity resemble gardeners rather than botanists, that the fact must be recognised that we classify for convenience rather than upon a scientific basis, because in point of fact no such basis, or finality of mode, has as yet been discovered. And perhaps little wonder, since many have to be treated as lunatics in whose brains and nervous systems we have found no change whatever. Unfortunately, this necessity of definition and classification to which I have referred may sometimes lend itself to misinterpretation, as in the pseudo-legal idea—which I regard as neither reasonable nor convenient—that every person of unsound mind is a lunatic. Obviously there are many persons of unsound mind who are neither dangerous to themselves nor to others—why, therefore, regard them as aliens? The true difficulty is that the disease insanity, as a definite entity, does not exist. Yet one might almost conclude from the elaborate articles which have appeared in our leading daily journal that it does, and that it is as definite in its symptoms and its origin as cancer or pulmonary tuberculosis. It is impossible for the physician to view abnormalities of mind, whether congenital or acquired, as having a common origin and requiring a similar treatment. There is no such thing as a bacillus of insanity. I have dwelt upon this point because one of the many difficulties which the study of the insane involves is the necessity of regarding them from so many different standpoints. The medical man concerns himself chiefly with the evidences of bodily disease to be discovered in the brain or one of its servants; the lawyer looks not so much to symptoms as to the questions of reason and responsibility; whether, in fact, the individual can recognise what he is doing and the consequences of it. The public at large considers chiefly questions of conduct, asking whether a person is dangerous to himself or to others. *Apropos* of the latter, we constantly meet with statements that many people are placed in asylums because they are troublesome rather than because they are dangerous; and it is also worthy of remark that there are many who desire that the feeble-minded and eccentric should have greater or even perfect liberty, so long as they are not a social danger. This point is, I think, rather well illustrated in the peculiar distinctions recognised on the popular side—thus, persons are spoken of as being “beside themselves,” or “out of their senses,” or “out of their minds.” To these you will note that I have already added my own conviction that many are really “out of their surroundings” and thus are aliens.

The conclusion then follows that, there being no definite entity of insanity, there can be no one comprehensive definition of it. And that the person is sane or insane in relation to his own standard and not to any existent arbitrary one, except the conventional arbitrament of civilisation. And as this varies the truth of my former remark becomes evident, that what is reasonable conduct in one man under certain conditions may be plain madness in another differently situated. I often think of a splendid young animal whom I saw—the son of a distinguished father who rightly judged his son to be an anachronism—out of place in fact; and considered that he would have made a fine knight in the Middle Ages, and perhaps even now might make a good cowboy in America. It becomes evident from such a case that there may be some who have a reason for attributing the causes of their insane position to their wrong surroundings. And here I would point out, as I have already hinted, that there is a sense in which insanity is merely a question of degree. For example, a small amount of miserliness may be all right; but, when you find it developed into the habits of the recluse, who starves himself though he has plenty of money, avoids all society, and neglects cleanliness and all the simpler conventions of life, he is treated as insane. Again, I knew a recluse, with plenty of money, who lived a hermit's life for 30 years or more, prowling about the streets at night, and lying in bed during the day; yet no steps were taken, as he did not interfere with society. But when called to see a similar case not so well off, I found that the authorities had already been called in. His small house being neglected was regarded as insanitary and he was removed to an asylum. Thus we see that similar conduct is, or is not, practically regarded as insanity according to the conditions. And if

there should be some who regard this view as of little importance from the practical or statistical standpoint—as referring, in fact, to a very small area in the wide field to be covered by the specialist—as not affecting in a vital degree the estimated sum-total of the insane, I am not in agreement. I still maintain that very many of the chronic insane owe their position largely to their surroundings, and the part which their surroundings and circumstances have played as a factor in the determination of that position is precisely what it is often important to consider before any reliable statistics can be built up in regard to the mental evolution or degeneration of the race.

With regard to a certain degree of a particular habit or feeling being considered normal, but its excess insanity, I may give the example of a very devoted husband who with advancing years dreaded the absence, even for a very short time, of his wife. Later he began to suspect that she was more absent than was necessary. Finally, though there was not the slightest ground for suspicion, he demanded from her a confession of her misconduct, calmly observing that he would forget and forgive. Thus, the overgrowth of natural affection and the suspicion of an imaginary sin have led, I fear, to a permanent delusion wrecking two lives. Where are we to look for the material basis of such a delusion? The conditions are still more complicated when the person proves to be a social misfit. There are some, like my cowboy youth, who are out of harmony with their surroundings from the first. There are others who as a result of education, disease, or other circumstances or causes, pass into a social grade different from their own. I have known public school and university men who have proved quite unfit for their natural home and yet they have done admirably as artisans. Are we to have a pathology for such conditions? Of course, a certain number of these social failures add to the numbers of the insane in our infirmaries and asylums. Undoubtedly, some may say there is some brain defect in these persons to account for their degradation; but how about the change of reformation; and in regard to those who have been converted, are we to have a pathology of conversion as well as of perversion? At any rate, the fact remains that not only from the social but from all other standpoints insanity is judged rather from conduct than from any known mental symptoms.

I will now in order proceed to consider the insanity of brain disease, the insanity of brain intoxication, the insanity of the truly neurotic type, the insanity of habit or association, and the insanity of function, simple disharmony, or want of accommodation. In considering these points I will give my experience as to the relative increase among them. First, then, there is a considerable amount of insanity depending upon natural decay of the nervous centres chiefly represented in the brain. The Commissioners give a table showing a considerable increase of longevity among the surviving senile insane. The chronic insane in asylums are like pensioners; they are removed from the stress and anxieties of life, they are carefully tended, and sometimes their very mental defect will lend itself to a calm which itself is favourable to a long life. Again, it is certain that, whereas in a former generation the old people were kept and guarded by their relatives, these latter are now more easily persuaded that they would, in their indifferent or mindless states, be happier in an asylum than elsewhere. And the infirmaries, on their part, are only too ready to transfer to asylums those who are not able to be of service in the wards and for whom they can get a bigger grant from public funds if they are sent to an asylum. Hence, the insanity of old age does certainly represent a considerable increase of the insane population. The forms of insanity associated with old age are not special in character, though many of them exhibit analogous features associated with loss of memory and loss of the senses of time, place, and relation. The insanity associated with premature decay, with toxic brain infection, is best represented by general paralysis of the insane. Here again, without doubt, there is considerable increase. In England, Scotland, and Ireland, all three, the Commissioners' reports prove this. Although we are at present unable to say that this disease proceeds from one definite source, there seems to be little doubt that syphilis added to alcoholic indulgence in city residents constitutes the chief cause. In England the progress is steady and it is interesting to note that this disease is now more prevalent among women than it used to be. This is markedly observable in Scotland. Women will have men's rights and with them they incur further risks. 40 years ago the

medical officers of asylums in Ireland used to come to Bethlem Hospital to see cases of general paralysis because they wished to assure themselves that they were not overlooking the disease. Personally I visited many Irish asylums in those days and I found very few cases of the disease, which now is common enough, particularly in the Irish asylums near cities. In America a similar experience has been recorded among the negroes, who before the Civil War rarely provided cases of general paralysis. Now they are common enough. In the last report general paralysis is stated to be increasing more rapidly in Edinburgh than in Glasgow. This seems hard to explain but I am inclined to think that more careful clinical examination in Edinburgh may account for the fact.

The next group to which I call attention is in many ways important and interesting, particularly at the present time, when toxins are the favourite explanation of most morbid states. I would, however, recall what Sutton said many years ago, that though there was doubtless much to be learnt from an observation of the relationship between micro-organisms and disease, yet, as effective causes, their importance might be over-estimated and their operation misunderstood, that just as we lived on, and aided by, them when healthy, so it was when we began to fail in any direction that the microbes were ready to prey on us. That mental disorder amounting to insanity may depend upon toxic influences is too well known to require much illustration on my part, yet it is perhaps worth while to note a few of the special forms of disorder which follow intoxications of one kind or another. First, then, there is generally a progressive affection beginning with the most highly specialised parts leading to defect in the last and most complex attainments, the continuance of such infection leads to further loss of power, and, as Hughlings Jackson has pointed out in his "Factors of Insanity," a letting loose of functions dependent on what he has called the lower or subordinated mental strata. It is thus that we get with loss of power, restlessness and delirium. A still further exposure to the influences leads to destruction of the parts and the annihilation of the functions. The result is a complete parallel to the decay met with in old age, which, I suppose, justifies Metchnikoff in his suggestion that senile changes depend on micro-organisms.

I have already spoken of neuroses and given some description, if not a precise definition, of them; and now, in natural order, I propose to consider the special forms of insanity which may be said to possess this common factor, that they are usually associated with insane or degenerating parentage. This class provides the largest number of long-lived residents in asylums, who used to be grouped together as demented. They generally come of insane stock and tend to transmit their neurosis, in one form or another, to their descendants. They are more liable than others to break down under slight stresses; *ceteris paribus*, their neuroses appear at the critical periods of life, such as adolescence, puberty, and, in the case of women, child-bearing and the menopause. These patients show a special liability to relapse after recovery, and, as a sequence, to establish a habit of recurring mental disorder—mania, melancholia, as the case may be. This morbid habit may become more and more organised and pass into regular circular insanity. The ease with which morbid mental processes are started in such cases is exemplified in the manner in which hallucinations of the various senses appear and develop; having appeared, they lead on in natural order to delusions of various kinds, to some extent coloured by the age, sex, education, and surroundings of the patient. But that persons even with fully-organised delusional insanity have any specially recognisable affection of their brains I deny. I daresay that in many there is some change of condition and in many also a defect of the highest powers; but as yet I am convinced we shall not learn much even from most careful histological observation. Without being a pessimist, I fear my experience is that such persons are slowly increasing in number and that no amount of drug treatment will have any effect upon them. If any good is to be done it seems to me that it is rather to be hoped for from the methodical and continued treatment followed in asylums. What cannot be cured must be endured and I fear that persons suffering from fully organised delusions are as little likely to lose them in many cases as they are to change their features.

With the above we have to consider, as depending upon a neurotic heredity, those who furnish examples of certain,

often recondite morbid modes of mental association—persons, in fact, suffering from so-called obsession. No reasoning seems to affect the beliefs or tendencies of these persons, yet in all other relationships their conduct may appear to be perfectly sane. Thus, a patient told me he knew it was a mistake, yet he dared not touch anything without gloves; another was afraid to sit in a chair without a preliminary dusting. He admitted that this was useless even if there were infection in the chair, all the same he must go through with it. Another patient, having been once bitten by a dog, was never free from the dread of hydrophobia, and though no signs existed of the dog ever having suffered from rabies, yet he could not go near the city where the accident happened. That with some of these morbid associations a physical basis bears a part I must admit, for this latter gentleman only comes to consult other physicians or myself when he is suffering from general symptoms of ill-health. On the whole I am not prepared to say whether there is any material increase among those suffering from obsessions.

To complete this part of the subject I must name the allied sufferers from the *folie de doute*. This may be taken to depend on different causes in different persons. The highly-trained legal mind may be so evenly poised that it cannot come to a conclusion; and the individual who suffers from this condition, or from its allied state of *Grübelnucht*, is suffering from a disorder which I cannot associate with brain disease. In regard to development the manner in which a simple natural idea may pass into a morbid one is shown in the following case. A well-educated man of good social position fell in love with a lady of good birth who in consequence of the ruin of her father found it necessary to give dancing lessons in order to earn money. The idea that she might expose her ankles to strangers so possessed him that he felt life intolerable, and no amount of argument that the lady was only teaching girls produced any effect. Again I have met with several doctors' wives who have developed an insane jealousy in consequence of their husbands attending midwifery cases. Thus, obsessions developed after the manner I have indicated have had serious practical effects, though in the cases to which I have referred the seclusion of the sufferers was not required.

Again, the perfectly natural way in which ordinary feelings may lead to insane developments is well illustrated in such cases as the following. A young man early in life becomes deaf; at first he feels the loss to be a very real and personal one, but he is content to do his best under the new limitations. Later he experiences several disappointments, probably in love; no doubt depending on his unfitness. Slowly he builds up a delusion that people shun him; gradually he becomes convinced that there is an organised system of annoyance. An insane or violent act may be the first indication of the progressive mental disorder. This is a case clearly associated with physical defect, but one constantly meets with patients endowed with a mere peculiarity which they think influences people against them. For example, a man with a scar on his nose believed that this was looked upon as the "mark of the Beast." Another, who had led a seafaring life, was certain that every one recognised in his scar evidence that he had had syphilis. Apart from personal defects or peculiarities one meets with many in whom a disharmony with the social environment has given rise to a morbid mental growth. A widow with small means has to reduce her expenditure. She believes her neighbours shun her; from this she develops a whole system of suggestion, innuendo, and annoyance, which may cause her to injure herself or her children, or perhaps to appeal to the police. Such cases are of everyday occurrence and I rather presume they tend to increase with the complexity of urban life.

Allied to such cases are those which I place under the heading "conscientious." Almost daily I see cases, generally young, of both sexes who, living their homelife and regarded as most quiet and well-behaved persons, have nevertheless slowly withdrawn from all intimate friendships, they have taken to self-improvement, they lead laborious days and often studious nights. They are said to be scrupulously conscientious. I often find them morbidly sensitive. Often they go on thus for years before it is discovered that brooding has led to the hatching of delusions of persecution. Here I suppose there is probably an unhealthy nervous system, but I do not think it is such a one as will in the material part of the brain be shown to be defective. This kind of case is frequently illustrated in the only sons of

widows who live their quiet life surrounded by female relations only. This class includes a large number of persons who drift into delusional insanity. I am fully aware of the fact that there are hundreds or thousands living similar lives who do not break down nervously, and that there are other elements in the situation. What I wish to enforce from the standpoint I have chosen is that such persons must be treated by change of condition and not merely by bedside study.

It will be seen that in all the cases to which I have been referring I deny the existence of any material pathology. I merely say that in those cases where the mutual reaction shows a distinct degrading influence in the surroundings of the individual it is more or less hopeless to look for any real uniform material cause in the person himself. Of course, I allow that variable bodily states may dispose a person to be more readily affected by his surroundings and therefore more unstable. But I shall have failed altogether if I have not shown that there are many nervous conditions in which the visible defect is one of arrangement and accommodation rather than destruction of any portion of the material basis of mind. I cannot therefore accept much that Hughlings Jackson has written in his "Factors of Insanity," because while he regards mental symptoms as the morbid product of the brain he does not sufficiently recognise them as a resultant of the forces of the environment. That every idea and every delusion have a representative in some material change in some part of the nervous system of course I do not deny: but that there are always definite changes which are the equivalent of insanity, I do deny. Before leaving this part of my subject I must refer to functional mental disorders. I cannot admit that all these have any material pathological basis. In fact, I still maintain that there are such things as functional mental and nervous disorders.

Let me quote what the late Dr. H. G. Sutton wrote on this matter: "Failure of function leads to organic destruction. It used to be taught that structure makes function, but it is the reverse, just as the blacksmith makes the horseshoe, fitting the iron for service. In nature it is evident that all function is making union—a living and a loving—while in disease there is disunion." Finally, unless we admit the supreme importance of surroundings both in giving rise to and in sustaining mental perversion, we cannot fully recognise the equally supreme necessity of judiciously modifying those surroundings and conditions in order to effect a salutary change.

To pass on, there was a girl admitted into Bethlem Hospital suffering from acute mania. After some weeks, quite suddenly, all the maniacal symptoms disappeared but she was paraplegic. The state of paralysis lasted for some weeks, to be again replaced by mania, which in its turn was again followed by paraplegia. Eventually the paraplegia slowly passed off, leaving the patient sane in body and mind. Certain other cases in which neuroses are interchanged are interesting: thus, sufferers from asthma or hay fever will lose these affections while suffering from another form of neurosis. I cannot find anything but a dynamic pathology for some of these cases of sudden cure. I have known patients apparently demented for years suddenly, without any bodily change, wake up perfectly sane and with no loss of mental power. A watch may lie inactive, for want of winding up, for years and yet not decay. The mind seems capable of resting in the same way. In this case we must faintly call it apparent dementia.

The next part of my subject—a brief reference to what may be called the ordinary forms of mental disorder—is, I think, less likely to give rise to any differences of opinion. First there is mania, the loss of higher mental control, which really extends from delirium to hysteria. As Jackson has pointed out, the removal of the higher control facilitates the demonstration of the lower activities of mind and also allows them to assert themselves in an abnormal manner. I am then inclined to think there is an increase, though not a very large one, in the cases of acute delirious mania—grave delirium, as it has been called. This disease is doubtless the result of some toxic influence and will furnish evidence of what I have said elsewhere that anything which will produce temporary delirium may give rise to delirious insanity. It may follow infectious fevers, alcohol, or some auto-toxins, arising, I have little doubt, in many cases from initial brain changes. I think, judging from my own personal experience, that the result—or, at any rate, one of the results—of reduced consumption of alcohol is that there are

found fewer cases of grave delirium arising from or following delirium tremens. As to ordinary mania, the general opinion I find among the metropolitan asylums is that there are fewer cases of simple mania than formerly, and that certain forms of mental disease which used to begin with mania are now more commonly seen in a melancholic state. This is said to be the case in adolescent insanity and also in general paralysis of the insane. This conclusion has by some been attributed to the part played by influenza in starting the neurosis, for there is no doubt that, as a rule, melancholic states are more common after this disease.

Next as to melancholia. You will gather from what I have just said that my own experience, which appears to be supported by that of most asylum physicians, is that there is an increase of melancholic patients and also of melancholic symptoms in the various forms of insanity. The self-conscious youth is religiously depressed. The girl with amenorrhoea is contrite and self-accusing. Middle-aged men and women are suspicious and doubtful as to their social position or their conduct in the past; with advancing years comes a dread of poverty and the workhouse, and perhaps the desire to leave a world where they feel that they have already begun to outlive their welcome.

The next general form of insanity, to which I have already several times referred, is so wide and so far-reaching that I am not surprised to find an almost universal belief in its increase. Dementia is the termination of many forms of insanity. As I have already pointed out, we have to deal with the fact that the insane live much longer than they did: they remain till the end in asylums and are frequently recognised in statistics. Again, a tendency to senile disorders leads naturally to an increase of senile dementia. So there are more old people to become insane and the insane live long enough to become old. I have little doubt that the various types of youthful disease tend more rapidly to mental weakness than they did in former years, but this is rather a belief than a proved fact. As to the various forms of dementia—such as those depending on syphilis, general paralysis, or alcohol—some are increasing, others are stationary, at present.

Under the head of "functional disorders" I referred to the truly neurotic insanities and I stated my conviction that they were increasing. I would point out that here again we ought to be on our guard. For it is pretty certain that these persons also accumulate in the asylums and live longer lives there. I certainly think myself that many among such persons might be allowed to live free at least from asylum control. I have not referred to the large class of idiots, imbeciles, &c., as I do not personally claim enough knowledge to speak about them. I do not, however, think it can be denied that there is a very large and probably increasing group of social failures, the failure depending on some nervous want. Some of these are physically unfit, others are wanting in their senses, while many are morally weak and unfit for ordinary social life. Whether these are increasing in proportion to the population I cannot say, but that in the future they will have to be seriously considered I do not doubt.

And now to sum up shortly what I have been aiming at to-day. I have desired to make it clear that I cannot accept any definition of insanity as a disease. I have endeavoured, briefly to delineate its social, legal, and medical aspects, each of which differs from the other. I have referred, in the time at my disposal, to the forms of mental disorder which appear to be the most interesting and worthy of consideration at the present moment. I have expounded my belief in the existence, or the non-existence, of a pathology for such cases, and I have given a few details here and there as to the increase of the various groups. If I should be considered to have expressed too hasty a conviction in regard to certain cases, which, being out of harmony with their surroundings and obnoxious to society, are in our day treated as aliens: I would nevertheless repeat my opinion that although insanity cannot be predicated of that which is neither a mental nor a physical organism, although I cannot go so far as to say that the insanity lies in the environment itself, yet in not a few cases the actual source, and especially the sustenance of the disorder, do lie in the surroundings rather than in the patient; and to a judicious and well-advised modification where possible of the surroundings and circumstances only can those interested look, with any prospect of success, for the desired safety, convalescence, or cure.

An Address

ON

THE RELATIONS OF LARYNGOLOGY AND
RHINOLOGY TO GENERAL PRACTICE.*Delivered before the Medical Society of University College
Hospital on March 13th, 1907,*BY SIR FELIX SEMON, K.C.V.O.,
M.D. BERLIN, F.R.C.P. LOND.,

PHYSICIAN-EXTRAORDINARY TO HIS MAJESTY THE KING.

MR. CHAIRMAN AND GENTLEMEN,—Whilst specialism in medicine has never enjoyed the favour of the profession in this country, laryngology and rhinology from their very inception as a special branch have been particularly unfortunate in this respect. When 30 years ago I began to practise as a specialist laryngology was indeed in a sorry plight, both so far as its popularity and its official recognition were concerned. The laryngoscope was almost universally looked upon as "a physiological toy"; special provisions for teaching its use had been made in hardly any of the general hospitals; throat departments, where they existed at all, were placed under the care in rotation of members of the assistant staff, special knowledge of laryngology evidently not being looked upon as a necessary requisite for teaching it; the special hospitals were altogether under a cloud, and the most prominent representatives of laryngology in anything but high favour with their fellow practitioners. A lurid illustration was given of the general feeling existing towards laryngology at that time by an address on "Specialism in Medicine" oddly enough delivered before this very society in 1881¹ by a respected leader of the profession, from which I quote the following significant passage:—

"There are many other points on which I should have liked to speak to you, of the specialisms that have so limited an area, that it is quite impossible for any man, who is restricted to any of them, to make an income, unless he does so by inducing his patients to pay him needless visits; such, for example, as to touch his throat with something every day, to turn the screw of his instrument for the back two or three times a week, or to do something to the Eustachian tube with equal frequency. But what I have said is enough to guard you, I hope, from falling into these mistakes, these 'worse than crimes, these blunders.'"

Although these statements were not allowed to pass unchallenged, and although the author himself deemed it prudent subsequently to modify his violent attack, there is no doubt that his remarks accurately enough represented the general feeling with which laryngology—rhinology was then hardly out of its teens—at that time was looked upon in this country.

That a subject, which was thus held in ridicule and even contumely by the leading spirits, should not have met with much acceptance amongst the rank and file of the profession is but natural. Indeed, without much exaggeration it might be stated that, unless some palpable lesion, such as considerable enlargement of the tonsils, was present the treatment in those times of throat affections of any kind on the part of the general practitioner was of touching simplicity and uniformity. First of all, a gargle of some kind was prescribed; then, if this had been of no avail, the patient was given some glycerine and tannin to paint his throat with; next, the practitioner himself painted his client's throat with a solution of nitrate of silver; and, finally, when this too had failed, the uvula was amputated. Indeed, I am not quite sure whether one can speak of this period as entirely past and gone.

Already at the time, however, when the just quoted scathing criticism was passed the outlook had become somewhat brighter. In glancing over an old paper of mine on the treatment of acute and chronic laryngitis in adults² I find that in 1880 I ventured to predict that laryngology in not too distant a time would occupy a position equal to that of other recognised specialties, and this prophecy began to be fulfilled already in the following year when at the London International Congress of Medicine the work of the subsection of laryngology, which was the first official recognition of the legitimacy of laryngology as a special

subject, convinced a good many former opponents that there was more inherent good in it than it had so far been credited with. Since then a quarter of a century has elapsed, and the question may now fairly be asked whether my prediction has come true in all respects. Well, it can, of course, not be denied that we have made a good deal of progress all along the line. The disdain in which laryngology was held has to a great extent given way to a better understanding. Questions of personal unpopularity of its representatives are no longer allowed to influence an appreciation of the subject itself. Special departments for throat diseases nowadays exist in all the large London hospitals and are in most of them confided to the care of specialists, and the special hospitals have emerged from the unpleasant position they held 25 years ago. Further, a special section for laryngology and rhinology is now granted in conjunction with otology at all the meetings of the British Medical Association, and there will be a section of laryngology and rhinology in the Royal Society of Medicine, which is now in process of formation, whilst up to the present the special subject has been cultivated in two societies devoted to its study.

Thus, certainly, considerable advance has been made since 1881. Candour, however, compels me to say that much still remains to be desired. Even now specialists are but too generally considered as belonging to a lower grade in the medical hierarchy—as if a man, who confined his labours to a limited sphere, and did lasting good work in this, was not as good as one who worked on many subjects without achieving distinguished success in any of them! But this consideration does not seem to be generally admitted. Witness the rarity with which positions of honour are accorded to laryngologists in the colleges and at the medical societies; anomalous restrictions are still placed at some hospitals upon the incumbents of the throat departments preventing them from performing external operations, so that the ridiculous position may be, and indeed has been, engendered that a man who holds the record of the world for a particular operation is not allowed to perform it at his own hospital; and, finally, and worst of all, the importance of the subject for their future practice is not made clear to the students, there being no compulsory attendance of stated duration at the throat departments, nor any certainty that the knowledge of the candidate with respect to this special branch will be tested at any of the final examinations.

When I speak like this, gentlemen, I am afraid that you will look upon me as one of those well-meaning but ill-advised persons who endeavour to burden still further the already over-burdened student, and this, indeed, has been the motto under which my repeated requests for compulsory attendance at the throat departments and testing of the candidate's knowledge at the final examinations have been declined by two of the examining bodies with which I am connected. But, gentlemen, believe me, nothing could be further from my intentions than to do such a hateful thing as to throw additional burdens upon you. The remedy for what I conceive to be the at present somewhat anomalous condition of medical education in this country lies, in my humble opinion, in a readjustment of the curriculum and in considerably more time being given to the study of those subjects which will be of practical importance in the life of the future general practitioner, whilst those subjects which though admirable in themselves are of little or no use for general practice, and are as a rule almost immediately forgotten when once the examination has been passed, should be proportionately restricted to their proper limits.

This is not the occasion to enter further upon this subject beyond saying that fortunately I do not stand alone, but that the justice of what I have just been saying is now being generally recognised, and that a strenuous effort is being made just at this moment to bring home to the authorities the necessity of a change in the sense that greater scope should be given to clinical medicine during the curriculum. What we want is not, of course, to educate our students to be specialists in every branch. Such an undertaking would be impossible in view of the limits of the time of study. But it ought to be possible, as it has been found to be in other countries, to teach sufficiently every student the use of the instruments of precision to be able to diagnose simple and straightforward cases of any kind, and not through ignorance of these methods to let cases, which at their commencement would have been perfectly amenable to treatment, slide until they are past help and recovery. That the laryngoscope

¹ Oct. 15th, 1881, p. 655 et seq.
² Jour., Jan. 24th, 1880.

and rhinoscope belong to these instruments of precision I hope to be able to show you from a few examples which graphically illustrate their importance.

If it were only for the sake of the laryngeal complications of tuberculosis, every practitioner ought to be able to discern for himself in a case in which a phthisical patient complains of his throat, whether there are actual tuberculous lesions present in the larynx or not. The fact has been ascertained by reliable statistics that every seventh person in this world dies from pulmonary tuberculosis. Again, it has been found that every fifth person suffering from pulmonary tuberculosis has got a laryngeal complication. Thus, in other words, on the average every thirty-fifth person coming under your care will be found to be afflicted with a serious complication of one of the most serious maladies we have to deal with. And this complication does not merely arise in the last stages of pulmonary tuberculosis, but is present in an unexpectedly large proportion already at its commencement. Last autumn I had, as a member of the consulting staff of King Edward the Seventh's Sanatorium at Midhurst, to pay my first visit of inspection to that institution. At that time there were 67 inmates in the sanatorium. Not less than 17 of these—I found to my own surprise—were shown to me as suffering from their throats in one way or the other, and of these not less than 14 were found to have genuine laryngeal tuberculosis. This number practically corresponds to the general percentage of laryngeal complications in pulmonary tuberculosis which I have given you. But the surprising thing is, that—admission to the sanatorium being strictly limited to the very early stages of pulmonary consumption—the proportion of laryngeal complications should have been so great already in these early stages. In almost all these cases it was possible to hold out a hope that with complete vocal rest and appropriate local treatment in some of them it would be possible to arrest the laryngeal complication. Three weeks ago I again inspected the sanatorium. The personnel of the inmates meanwhile had, of course, considerably changed, but the percentage of throat complications at the time of my visit was exactly the same—viz., 20 per cent.—and, what was most pleasing, in a good number of the patients afflicted with laryngeal tuberculosis, whom I had seen on the occasion of my first visit, considerable improvement or even arrest of the disease had been obtained. It may be found, of course, on longer continued observation that the percentage of laryngeal complications in these early stages is somewhat smaller than it was on the occasion of my two visits, but even if this were so, are not the facts just stated alone sufficient to show you the importance of the laryngoscope and to justify my demand that every practitioner should be acquainted with its use?

Let me give you another illustration. A few weeks ago I introduced a discussion on the diagnosis and treatment of laryngeal cancer at the Medical Society of London. In my introductory remarks I stated that I had seen in private practice between October, 1887, and December, 1906, 212 cases of malignant disease of the larynx. Of these 136 were intrinsic and 76 extrinsic or mixed. (I should state here that according to general custom all cases of malignant disease of the larynx are nowadays divided into two large classes—viz., the intrinsic, which comprises the cancers originating within the laryngeal cavity, and the extrinsic, which comprises those cases in which the disease is situated on the epiglottis, aryepiglottic folds, or the oesophageal aspect of the cricoid cartilage.) These two classes diametrically differ from the therapeutic aspect, inasmuch as the intrinsic variety, if only diagnosed early enough, permits of a prognosis better than that of cancer in almost any other part of the body. Indeed, I was able to state that of the 25 cases of intrinsic cancer of the larynx, which I had operated upon by means of thyrotomy, not less than 80 per cent. had been lastingly cured. Most of these patients have a good or fair, a large proportion an astonishingly good, voice, and hardly any of them is prevented from following his previous occupation.

Extrinsic cancer of the larynx, on the other hand, can only be attacked with any prospect of success by total laryngectomy and removal of the cervical glands. The mortality from this operation, although no longer so appalling as it was some years ago, is still considerable—viz., 19 per cent. Recurrence according to the latest statistics takes place in 24 per cent. and life in the great majority of cases, which have been successfully operated, is anything but pleasant, the patient being deprived of the power of ordinary speech and reduced to a pharyngeal whisper, whilst in

not a few cases difficulty in swallowing is also present. Thus you see that the prospects of the two classes of laryngeal cancer are, indeed, as I just stated, extremely different from one another.

After the meeting in which I had stated my experience a distinguished laryngologist asked me how it was that I had seen so preponderating a proportion of intrinsic cases whilst he in hospital practice had found an almost inverse preponderance of extrinsic cases. The explanation I was able to give him is extremely simple; he refers to his hospital practice, whilst all my statistics relate to my private practice. Now there is the great difference between these cases in private and in hospital practice, that whilst in the former patients who are troubled by nothing else but by persistent hoarseness—which in the great majority of cases is the first and for a long time the only symptom of this variety of the disease—consult their general attendant or a specialist already at an early period of the disease, hospital patients, as a rule, do not take any notice of such hoarseness and allow the insidious disease to go on, until it passes over the confines of the larynx proper, when pain, difficulty in swallowing, enlargement of the cervical lymphatic glands, and general cachexia are induced, and when the case no longer belongs to that class in which the simple operation of thyrotomy will cure them, but when the much graver recourse to total laryngectomy represents the only possibility of saving them.

Here, then, is another illustration of the necessity of the use of the laryngoscope in private practice. You ought not to be satisfied when a middle-aged patient comes to you complaining of hoarseness of several weeks' duration, for the occurrence of which he can give no explanation, in assuming, without making a laryngoscopic examination, that he is merely suffering from a laryngeal catarrh. You ought to use your laryngoscope, and when you find congestion limited to half of the larynx only, or a suspicious thickening, or a distinct outgrowth from one vocal cord, send your patient at once to a competent specialist in order not to lose precious time. Many a valuable life will be saved, and indeed has been saved, by such prompt recognition on the part of the general practitioner, in whose hands, indeed, in the majority of these cases lies the patient's fate.

One more fact will illustrate the same point. A patient may come to you with various vague complaints about early fatigue, pains in his head, chest, or abdomen, shortness of breath on exertion, and similar nondescript or ambiguous symptoms which may be due to an immense variety of causes. You carefully examine him in the approved manner, you find no organic change to explain these symptoms, and you console him and yourself with so cheap a diagnosis as that of his "being out of sorts" or "neurasthenic," &c. Yet, if you had included amongst your investigations an examination by means of the laryngoscopic mirror you might have found one sign positively characteristic of organic disease, and at once drawing your attention to quite a variety of serious organic affections, of which its appearance may be, and often enough is, the first and for a long time the only demonstrable sign, viz., abductor paralysis of one vocal cord. The mere enumeration of the principal of these diseases—tabes dorsalis, syringomyelia, amyotrophic lateral sclerosis, bulbar paralysis, pachymeningitis, aneurysm of the arch of the aorta, malignant mediastinal tumours, pleuritic thickening of the apex of the right lung, oesophageal carcinoma, &c.—will suffice to show you the enormous practical importance of this sign, which is so easy to detect but which must be sought for in order to be detected, as it does not reveal itself either by changes in the voice or in the respiration.

It would be easy to multiply the number of examples demonstrating the value, nay, the necessity, of the use of the laryngoscope in general practice. Thus, I just mentioned that hoarseness often is the first, and for a long time the only, symptom of intrinsic laryngeal cancer. But apart from this, consider what a multifarious significance that symptom, which so often brings the patient to a cancer that symptom, may have. Hoarseness may be a sign of a simple catarrhal process, of laryngeal tuberculosis, of syphilis, of the existence of an innocent or malignant growth in the larynx, of laryngeal paralysis, of the ingrowth of a foreign body in that part—in fact, of conditions as different in kind as in requiring different treatments. To treat such symptoms in mere routine fashion by prescribing an inhalation, or a spray, or an expectorant

without even looking at the larynx means, bluntly speaking, neglect of duty, and exposes, I need not say, the practitioner if the real cause be afterwards detected by somebody else to the reproach of carelessness or ignorance. The same applies to laryngeal dyspnoea, which may, as you know, be due to such different causes as oedema of the larynx, perichondritis, tuberculosis, syphilis, or malignant disease, laryngeal neoplasms, spasm, bilateral paralysis of the abductors, impaction of a foreign body, external compression, stenosis remaining after diphtheria or typhoid fever, fractures or injuries—conditions again, as you see, as widely different from one another as could be, and in most cases reliably differentiated only with the help of the laryngoscope.

Turning now to affections of the nose, let me remind you in the first place of the great influence exercised by stenosis of the nose and naso-pharynx upon the general health and more particularly upon the tendency towards catarrhal affections of the air passages. Perhaps no progress made within the last 40 years in the field of laryngology and rhinology has more thoroughly influenced the minds and has more generally entered the thoughts of the bulk of the profession than the effect of the most frequent form of naso-pharyngeal obstruction—viz., of adenoid vegetations—upon the general development of children. It is fully and generally recognised nowadays that chronic obstruction of the naso-pharynx during childhood not merely brings about such unpleasant results as mouth-breathing, frequent colds in the head, and periodical or permanent deafness, but that it also leads, when long continued, to insufficient oxygenation of the blood, deficient development and deformity of the thorax, and to mental hebetude, leaving alone the fact that the unhealthy condition of the naso-pharyngeal mucous membrane predisposes towards infection of different kinds, and that if such infection has taken place it is apt to run a more severe course and more particularly to cause ear complications. But apart from adenoid vegetations the importance of stenosis of the air-passages proper is of such a character as to force itself time after time upon the mind of the thoughtful practitioner. When you once enter upon private practice you will find that the graver diseases of mankind to which your attention is more particularly devoted during your years of study fortunately are not those with which you have to deal most frequently, and that affections which you have been apt to consider as trivial during your student years after all occupy a much larger part of your daily work. Amongst such trivial complaints of which you are likely to hear almost daily in your practice perhaps none will be more frequent than that about a particular tendency "to catch cold." "I catch cold on the slightest or on no provocation," you will be told, "and every cold directly flies to my throat and chest." In a large number of the patients consulting you for that complaint you will find on examination the typical face of the mouth-breather, with oblong configuration of the head, pinched nose, retracted upper lip, and prominent incisor teeth. They may give you a history making the presence of adenoids in childhood very probable. You elicit the fact that the patient always keeps his mouth open, snores at night, and awakes with his throat parched and dry. On examination you find, apart from the symptoms of general catarrh of the upper air-passages, genuine nasal stenosis due in some cases to general narrowness of the parts, more frequently, however, to deviation of the septum or enlargement of the turbinates, or a combination of both these changes, associated possibly with abnormal steepness of the hard palate. No remedy is, in these circumstances, likely to diminish the catarrhal tendency, unless proper nasal breathing is restored. That judgment in these cases is required goes without saying; to attribute every cold to nasal stenosis and to proceed by means of operation against perfectly harmless small excrescences from the nasal septum or slight enlargement of the turbinates, which do not in the least prevent the patient from breathing freely through his nostrils, is just as injudicious as to hold every slight amount of lymphatic tissue in the naso-pharynx as responsible for every kind of obscure neurosis in the body and surgically to proceed against it as being the certain cause of those nervous disturbances. But when proper caution is exercised, cases enough still remain in which the catarrhal tendency will really be benefited by the restoration of nasal breathing, and the attainment of this desirable purpose rests in the first place with the diagnostic powers of the general practitioner.

Exactly the same obtains with regard to the affections

which I select as a final example of the importance of the general practitioner's knowing something of laryngology and rhinology—viz., empyema of the accessory cavities of the nose. I do, of course, not speak in this connexion of those cases of empyema of these cavities in which urgent local symptoms cry out, as it were, for attention on the part of even the most casual observer, but I refer to those categories in which either there is no, or very little, periodical discharge (latent empyema) or in which nasal discharge has become, as it were, so much a part of the patient's existence that he either does not refer to it at all, or only incidentally, when consulting his medical adviser for what appears to him a trouble of a very different kind. In the first of these two categories (cases of latent empyema) the patient's only complaints may be headache or neuralgia (permanent or periodical, general or more frequently limited to the frontal region, vertex, or the occiput, according to the cavity affected), combined in more advanced cases with eye troubles, general depression, loss of memory, or somnolence; in the second class, in which, particularly during sleep, there is more or less continuous drainage of pus into the stomach and auto-infection of the system, the complaints may only refer to grave dyspepsia and general feeling of being unwell. If, in the first of these categories the practitioner is satisfied with treating his patient as neurasthenic and with ordering simply change of air and residence, sedatives, &c., and if, in the latter, he looks upon the disease as originating from, and confined to, the digestive organs, and treats the patient accordingly, he will, needless to say, never be able actually to cure him, and will sooner or later in all probability have the chagrin of finding that he leaves him to seek other aid. If, on the other hand, in cases of this kind he thinks at an early period of the possibility of a nasal origin of the obscure headache or dyspepsia, and either succeeds in diagnosing himself the existence of an empyema, or sends his client for confirmation of his suspicion to a specialist, who confirms it, he may be sure that this proof of his diagnostic acumen will greatly redound to his credit in the eyes of the patient and his friends.

The foregoing examples will suffice, I trust, to convince you, gentlemen, that an acquaintance with matters laryngological and rhinological, even though these branches do not yet occupy in the medical curriculum and in the final examinations the position which they deserve, is nowadays indispensable for the general practitioner who does not wish to be left behind in the struggle for existence. That no undue demand should be made with regard to the extent of this knowledge I heartily admit. In a previous part of this address I have expressly stated that it is an impossibility to educate our students within the time of the official curriculum to be specialists in every branch of medical science, and I am further fully aware that similar claims to those raised for my specialty could with equal reason be adduced on behalf of many other of the special branches. But it is not necessary that every general practitioner should be a specialist for everything. He will do justice to himself and to his patients when he possesses sufficient knowledge to diagnose and treat simpler cases himself, and to recognise at a sufficiently early period in difficult and obscure cases that further help is required. In the words "at a sufficiently early period" lies the whole crux of the question. The time ought to be over when a patient with beginning cancer of the larynx is sent to a watering place, when a beginning bulbar paralysis is treated with amputation of the uvula, when a tuberculous ulceration of the larynx is allowed to extend until it is past the limits of possible help, when an empyema of the frontal sinus remains unrecognised until caries and necrosis of the walls of the cavity occur, accompanied by meningitis or encephalitis. Not in treating for an indefinite length of time an obscure case with all possible remedies without endeavouring to establish the correct diagnosis lies the wise policy of the general practitioner, but in calling in help at the time when help can still be given.

Here the big question of the proper relations of the consultant and the general practitioner opens, and although this question is, of course, much wider than the immediate purpose of this address, the subject of the latter is so inseparably bound up with the general question that I trust you will bear with me if, in conclusion of my remarks, I dwell for a few minutes on one aspect of this all-important topic which is of particular interest in connexion with my observations. More than once I have emphasised in the course of my remarks the impossibility of educating our

students to be specialists in everything. This, however, I trust will not be understood by any of you as meaning that I wished to relegate the general practitioner to the humiliating position, that he should only prescribe for colds and stomach-aches, and that for the rest he should merely act as an adviser as to who should be called in, when the matter became slightly more serious or obscure. It would be an evil day for the science and art of medicine, and for the self-respect and sense of responsibility of the general practitioner, if such became the general practice. But what I contend he ought to know is: the limits of his own knowledge and that he ought to act upon this recognition of his own limitations. It is not a sign of strength, but of weakness if a practitioner misguided by a false sense of shame obstinately refuses to recognise that he has arrived at the end of his own powers, and if with equal obstinacy he refuses to let his patient have the benefit of further advice in conjunction with himself. Apart from the grave responsibility thus engendered, he certainly does not strengthen his own position by such a short-sighted policy. The times are fast approaching their end when the patient consented to be looked upon as a piece of property on two legs, and nowadays when he finds that his general medical adviser has done him no good by a prolonged course of treatment, and has neither suggested himself nor received with favour his own timid suggestions as to a consultation, he takes his fate into his own hands and clandestinely consults someone else. Remember, gentlemen, it is his own usual medical attendant who has driven him to adopt that course!

Here the difficult task of the consultant begins, a task not rendered any the easier by the wholly or partly erroneous views, which unfortunately appear to be entertained on this point by a good many general practitioners. It seems to be thought by them that the patient who comes on the sly to the consultant begins the conversation by saying: "I have been under the care of Mr. So-and-So for a long time and am still under it, but as he does me no good I have come to see you." Now let me assure you, gentlemen, on the strength of nearly 30 years' experience as a consultant, that a patient introduces himself in such a manner on the rarest of occasions only, when every decent-minded consultant would at once interrupt him and say that as he was still under Mr. So-and-So's care he (the consultant) could only see him with the general attendant's knowledge and consent. But, as a matter of fact, in the great majority of all cases the patient either begins by at once telling the consultant the symptoms of his complaint or he states that he had received certain advice with regard to an operation or other form of treatment and that before consenting to it he wished to take a further independent opinion, a course to which I think he is fully entitled. In not a few cases he merely asks to be examined, in others he positively denies having a general medical attendant; again in others he may tell you that he had suggested a consultation but that this had been declined, or say that he was not satisfied but did not wish to hurt his feelings, and had given up attending his usual medical attendant, &c. Frequently enough it is quite impossible to ascertain the true condition of things. In fact, the number of contingencies is so great that I believe no code of ethics could be compiled in which they were all satisfactorily provided for. The consultant, therefore, must depend in almost every individual case upon his own judgment, tact, good fellowship, and desire to avoid making mischief. In a goodly proportion of cases he will find, of course, that the patient has been quite correctly treated, when it will give every honourable consultant the greatest pleasure to tell the patient so and to encourage him to continue with the treatment adopted by his general medical attendant. Not much good, I think, could come from the consultant's communicating in such circumstances with the general practitioner and, on the contrary, mischief might be done, inasmuch as the general attendant's susceptible *amour propre* probably would be still further wounded and a feeling of distrust be engendered in his breast against his patient. I think it, therefore, wisest and kindest for the consultant to treat such a consultation as a passing episode, after which the patient will, with renewed confidence, return to his ordinary medical attendant. But the course to be followed becomes infinitely more difficult and delicate when the consultant after examination arrives at the conclusion that a mistake has been committed with regard to either the diagnosis or the treatment of the case or to both. His *esprit de corps* forbids him

to disparage the opinion of the usual medical adviser, his duty towards the patient commands him not to let the latter continue under what he considers a mistaken *régime*. The obvious way out of this difficulty would seem for him to communicate with the general medical attendant, and to this course I have found in long experience the patient almost always, even if at first feebly protesting, ultimately consents, if it be explained to him that his case was not one for a casual stealthy consultation behind the back of his general medical attendant, but for hearty coöperation between the latter and the consultant. To this most natural proceeding, however, opposition has arisen in a quarter in which one should have least expected it; instead of appreciating that such communications are made not only in the patient's but most certainly in the general attendant's interest as well, some general practitioners violently resent what they call "unrequested advice," and many more, alas, have not a word of thanks for the consultant, who has endeavoured to keep for them patients who often enough were on the point of leaving them altogether when seeking independent advice! It is truly difficult to understand this mental attitude, but if proofs were wanted to show its actual existence I need only refer you to a correspondence on the ethical aspects of medical consultations which has taken place within the last few weeks.³ Personally I have been lucky enough to escape the "acrimonious and insulting replies" which have fallen to the lot of many a consultant, who wrote with the best of intentions to the practitioner in attendance, when the latter's patient had clandestinely consulted him, but speaking from memory I must say, with sincere regret, that in by far the larger part of all the letters I have written in former years in similar circumstances I have received no reply at all! Experiences of that kind do not encourage a man to continue in taking a good deal of trouble when the latter apparently is so little appreciated! It is my custom now, when I see a case in which in the course of the consultation it becomes apparent that the patient has been, and possibly may be still, under the care of another man, and in which I think that the latter in the patient's and in his own interest ought to know my own views, to tell the patient that if his medical attendant should wish to know my opinion and would write to me in that sense I should be very happy to report to him. The adoption of this course enables me to fulfil my duties towards both the patient and the general practitioner without exposing me to unpleasantness. Still, I am far from thinking that this course affords a healthy and truly satisfactory solution of the question. Yet it ought not to be difficult to solve it satisfactorily. All this internecine bickering would be done away with and a much more cordial feeling created between general practitioners and consultants if the former would only credit the latter with their true motives in writing to them about truant patients whose cases require further consideration.

In the cordial coöperation of the consultant and of the general medical attendant lies the true interest of everybody concerned. That this general principle, from the nature of the diagnostic and therapeutic questions involved, applies with particular force to the relationship of laryngology and rhinology to general practice I have endeavoured to illustrate to-night.

³ Brit. Med. Jour., March 2nd, 1907, p. 534

THE Medical Graduates' College and Polyclinic held its annual general meeting at 22, Chenies-street, London, on March 22nd, under the chairmanship of Dr. O. Theodore Williams. The annual report and balance-sheet, which were unanimously adopted on the motion of the chairman, showed that the polyclinic was in a prosperous condition and that its financial condition and other interests only require the individual assistance of its members and subscribers to enable the Council to widen the scope of the work and to increase the usefulness of the institution. In 1906 there were 14,528 attendances of medical men and 1164 cases of disease, many of them of extreme rarity and interest, were shown at the various clinics. In addition there were held four sessions of practical classes and one vacation course of three weeks attended by 198 practitioners. The medical superintendent of the polyclinic, Captain A. E. Hayward Finch, was heartily congratulated on the success of the college.

ABSTRACT OF

The Goulstonian Lectures

ON

CERTAIN ACUTE INFECTIVE OR TOXIC
CONDITIONS OF THE NERVOUS
SYSTEM.

Delivered before the Royal College of Physicians of London

By E. FARQUHAR BUZZARD, M.D. OXON.,
F.R.C.P. LOND.,

ASSISTANT PHYSICIAN TO THE NATIONAL HOSPITAL FOR THE PARALYSED
AND EPILEPTIC, QUEEN-SQUARE, TO THE ROYAL FREE HOSPITAL,
AND TO THE BELGRAVE HOSPITAL FOR CHILDREN.

LECTURE III.¹

Delivered on March 15th.

MR. PRESIDENT AND GENTLEMEN,—Having devoted the whole of my second lecture to the consideration of acute poliomyelitis, I have left myself but a meagre allowance of time for the discussion of the remaining and less common diseases of my group—namely, acute ascending myelitis, Landry's paralysis, and acute toxic polyneuritis. The task of dealing adequately with these morbid conditions in the time at my disposal would have been an impossible one if it had been my object to describe them in a systematic manner. My purpose, however, is, as I have already told you, of a different nature, and I shall merely place before the results of my own observations, and the grounds my belief that there are features, clinical as well as anatomical, by which these three maladies can be differentiated.

ACUTE ASCENDING MYELITIS.

It is a matter of some difficulty to choose between the terms "acute ascending myelitis" and "acute disseminated myelitis" because the one is probably better supported from clinical and the other more appropriate from a pathological point of view, but I have chosen to include the word "ascending" for the reason that it graphically suggests the prominent characteristic of the disease. "Acute ascending myelitis" would do equally well and is in most cases, at any rate, more correct. Reference to the meningitis, however, no more necessary here than is reference to the uræmia which undoubtedly complicates the great majority of cases of pneumonia.

Let me introduce the subject through the medium of a case. A bricklayer, aged 44 years, was admitted to the National Hospital for the Paralysed and Epileptic on August 14th, 1903, under the care of Dr. J. S. Collier. The patient's previous health had been good in every way and no evidence could be obtained either of venereal infection or of temperance. On August 3rd, 4th, and 5th he had noticed all pain about his chest, especially between his shoulders, and on the following day he experienced some weakness of his legs, although he was able to continue his work. Leaving his bed on August 7th he was conscious that his legs were numb and he found that he could not empty his bladder, but as he was able to walk a quarter of a mile. Inability to climb a ladder caused his return home and on the next morning he was unable to stand. On the 9th he did not suffer any incontinence when pins were inserted into the skin of his legs or abdomen and all power of moving his lower extremities had disappeared. Three days later he suffered from pains shooting down his arms, and this was followed within 24 hours by paresis of those limbs.

On admission to the hospital the patient was found to be a large, robust, and well-nourished man, completely unable to move his legs, to sit up, or to turn over in bed. The skin covering the trunk and limbs was pale and dry, a well-marked tache being obtainable on stroking. On the other hand, his face and neck were flushed and moist with perspiration. His lips and tongue were furred, foul, and dry. Mentally, the patient was clear but somewhat apathetic. The temperature was 101° F., the pulse was 72, and the cardiac condition was normal. Respiration was shallow, regular, chiefly diaphragmatic, and recurring about 23 times

a minute. There was no spontaneous cough and attempts to produce one were feebly carried out. The abdomen was distended with flaccid walls, nothing abnormal being detected on palpation. After much aperient medicine a continuous and uncontrolled expulsion of fluid feces was obtained. The urine, which had to be withdrawn by catheter, was scanty, high coloured, acid, and of a specific gravity 1030; it contained some albumin but no sugar. Examination of the function of the cranial nerves revealed no abnormality. The patient was able to turn his head from side to side and to raise it from the pillow in rather feeble fashion, but he could shrug his shoulders with fair strength. Both arms displayed complete flaccid palsy of movements at the wrists and finger-joints, whereas some diminished power of moving the limbs at the elbow and shoulder was still present. No wasting, tremor, or muscular fibrillation was observed. Respiration was carried on by the diaphragm and accessory muscles, the intercostal and abdominal muscles being totally paralysed. The legs were flaccid and quite powerless throughout but no atrophy was evident. The muscles everywhere responded normally to electrical currents. On the sensory side it was elicited from the patient that he had suffered from pain in the back and chest, with a feeling of tightness and burning around the lower abdomen, associated with numbness and tingling over the legs which gradually extended up the trunk. At the time of admission he was conscious of numbness from the feet to the nipples and a dull diffuse pain in the back. On testing his cutaneous sensibility it was discovered that prick and touch were unperceived up to the level of the nipples and only partially recognised as high as the fifth cervical root area, the right arm being more insensitive than the left. The sense of position was lost in all four extremities and no tenderness was present on squeezing the muscles. All deep and superficial reflexes were absent in the trunk and limbs, the jaw jerk, however, being easily obtained. On August 15th, the day after admission, moist sounds were audible in the lungs and the arms and respirations were more feeble. I inoculated culture tubes with the cerebro-spinal fluid by means of lumbar puncture and with blood from a vein which I opened under strict aseptic precautions. Death took place from respiratory failure early the following morning, less than 13 days from the first symptoms of pain and less than ten days from the earliest signs of paresis. During his stay in the hospital the patient's temperature varied between 101° and 102° 4°.

Twelve hours after death I performed a necropsy, finding rigor mortis present, the body well nourished, and the abdomen markedly distended. The dura mater was normal in appearance, the leptomeninges, on the other hand, being intensely congested, although free from visible exudation or pus. The spinal cord was softer than usual throughout its length but from the tenth dorsal segment to the lower cervical region almost diffident in consistence. On transverse section in this part it was impossible to distinguish white from grey matter and dark brown patches suggestive of extensive hæmorrhages were seen scattered about. Beyond general hyperæmia the brain presented no abnormal features. The left sciatic nerve was rather soft and fatty and the muscles appeared healthy. The heart and liver were normal, the lungs and kidneys were congested, and the spleen was soft, large, and deeply coloured. At the necropsy I inoculated culture tubes from the heart blood, cerebro-spinal fluid, and spinal cord.

The results of the bacteriological investigation during life and after death may be conveniently considered at once. Part of the cerebro-spinal fluid taken during life was centrifuged and the very scanty deposit was examined. It contained few cells but some organisms which are best described as diplo-bacilli—very short rods with rounded ends placed end to end, generally in pairs but sometimes forming irregular chains. Cultures from the cerebro-spinal fluid were sterile. Cultures from the venous blood extracted during life produced in broth only a slight turbidity and smears showed a diplo-bacillus resembling the one already described except that they appeared to be somewhat larger and stouter. All efforts to subcultivate the organism failed. All culture tubes inoculated post mortem proved sterile except the broth tube from the spinal-cord substance which again grew a scanty and short-lived organism resembling the one obtained from the venous blood during life. The organism I have referred to retained Gram's stain badly. Owing to failure in subcultivation I have no knowledge of its cultural characteristics and the only point of importance is the fact

¹ Lectt.
(p. 765) a

published in THE LANCET of March 16th
respectively.

that the bacillus was found in the blood and cerebrospinal fluid during life and the spinal cord after death. With regard to its causal relationship with the disease it is unwise to speculate further but it is well to remember Homen's experience which I referred to in my first lecture. That investigator was unable to find organisms in the cord more than a few days after their injection and I may add that in my case the search for bacteria in stained sections of that organ was unsuccessful.

Microscopical examination.—The parts examined included various levels of the brain and brain stem, the spinal cord, some peripheral nerves and muscles; the Nissl, Löffler's methylene blue, Busch, logwood and eosin, or van Gieson methods were employed. I may say at once that no changes were found in the sciatic nerve or in the anterior tibial muscle, and that changes in the central nervous system did not extend higher than the lower part of the pons. Speaking generally the most marked disease was found throughout the dorsal and lower cervical region, less marked disease in the remainder of the cervical region and medulla, and least disease in the lumbo-sacral enlargement. Taking this fact along with the clinical history of the case it is justifiable to assume that the morbid process originated in the lower dorsal region and spread upwards with somewhat fading intensity after reaching the cervical region as high as the bulb. At every level foci of acute inflammation were present, either confluent over the whole of a transverse section, as in some parts of the dorsal region, or discrete and irregularly scattered, as in the cervical segments. The incidence of these patches was chiefly on the white matter and especially on the posterior columns, but in the dorsal region the condition was so general that it was often impossible to differentiate white from grey substance or to detect any remains of the central canal. Whether the lesion was in the white or grey matter the essential characteristics were similar and it will be sufficient to describe one or two typical pictures as seen under the microscope.

For instance, a section through the mid-cervical region shows the posterior median artery and its branches engorged with blood and surrounded in its adventitial lymph sheath by a cellular proliferation practically identical with that seen in the cases of acute poliomyelitis. In the white matter surrounding the vessel the most noticeable feature is the great proliferation going on in the neuroglial cells, which is much more active in the immediate proximity of the vessels and fades off more or less as the distance increases. All, or nearly all, the neuroglial cells are enormously swollen and many contain two or more nuclei which are also large and sometimes vesicular. Vacuoles are at times present in the cell plasma. Among these cells are seen the remains of the nerve fibres with swollen myelin sheaths and swollen axil cylinders, the latter often five or six times their normal diameter. Here and there are spaces from which the myelin and axil cylinders have fallen. In a section showing their condition in only moderate intensity in the posterior columns one may find the grey matter practically normal and most of the anterior horn cells in a state of good preservation. On the other hand, in sections where the involvement of the white columns is more general it is usual to find the cells of the anterior horn swollen and chromatolytic.

Another characteristic picture is that presented by a portion of the white matter in which two or three small vessels are seen in transverse section. These appear engorged with blood which, although probably in a condition of stasis, shows no definite evidence of coagulation. Around the vessels is a dense ring of mononuclear cells, a little further away a zone in which there appear to be many polymorphonuclear leucocytes, and everywhere in the neighbourhood numerous neuroglial cells of all shapes and sizes scattered amongst granular debris or swollen nerve fibres. In similar situations large hæmorrhages have taken place and the blood is dispersed between the fibres so as to form for the latter in places a kind of dark framework.

In the soft meninges covering the cord, and also in the anterior median fissure, is seen a cellular proliferation; the majority of the cells are of the mononuclear type but a few are polymorphonuclear, and other varieties, which are difficult to classify, are also present. The Nissl sections emphasise the fact that ganglion cells are only degenerated in proportion to the amount of inflammation present, but, unlike acute poliomyelitis, the anterior horns may be free from inflammatory exudations and yet the cells swollen and chromatolytic provided that there are marked inflammatory lesions in the surrounding white columns. Sections from

the cervical and other regions stained by the Busch method show surprisingly little change, probably owing to the short duration of the morbid process, but a remarkable feature in these preparations is the presence of large droplets of fat in the meninges, the epispinal space, and undoubted evidence of degeneration of the fibres of the cord immediately subjacent to it. In this manner a narrow rim of scattered but large black dots can be seen just beneath the membrane. Numerous amyloid bodies are scattered about the periphery of the cord and along the rim of the great vessels. This case is typical of acute ascending myelitis, other examples of which may be found scattered through medical literature.

A very complete account of another fatal case was published by Dr. Thomas Buzzard and Dr. J. S. Risien Russell in the Transactions of the Clinical Society in 1898, the clinical features and morbid anatomy closely resembling those I have just referred to. Risien Russell succeeded in growing a diplococcus from the meninges after death which presented some characteristics similar to, but not identical with, those of the meningococcus and which proved pathogenic to guinea-pigs and mice. Rhein in 1904 recorded another example of the disease and his paper contains references to most of the preceding published cases. There has been sufficient bacteriological investigation to show that this morbid condition can be the result of infection by many different varieties of bacteria, and experimentally Marinesco has shown that an infective meningo-myelitis can be produced by several of the ordinary pyogenic organisms. Another point of interest to be gleaned from the literature is the evidence afforded for the belief that although this malady may arise in what appears to be a spontaneous manner in healthy subjects, it is not infrequently a secondary complication in cases of infective diseases of other organs. For instance, Sir Thomas Barlow described in 1887 the onset of symptoms of rapidly spreading paralysis in a man, aged 23 years, who was recovering from measles and who died in the course of 11 days. The cord showed changes which enable one to place the case in this group although the grey matter had suffered in a relatively greater degree than in some of the other instances. Outtlinger and Marinesco, and Auch and Hobbs have recorded a similar sequela in cases of variola, and Lépine believes that there is a definite typhoid myelitis of the same infective character. It is very probable, too, that many cases of so-called "primary paralysis" and the cases of acute ascending paralysis secondary to chronic cystitis described clinically by Walker should be placed in this category.

We may fairly assume, then, that acute ascending myelitis is an infective disease probably due to the presence of various bacteria in the tissue of the cord, and we have already seen that acute poliomyelitis is an infective process due to the influence of bacteria or their toxins. What is the essential difference in the pathogenesis of the two conditions which will explain the very different morbid anatomy, the different symptomatology, and the very different etiology in the way of age, epidemic, and seasonal incidence. I have in my second lecture laid before you my grounds for believing that acute poliomyelitis is the result of a poison, with neuroglial affinities, circulating in the blood stream. There is still stronger evidence, to my mind, in favour of the view that acute ascending myelitis is the result of a bacterial infection of the lymphatic system of the spinal cord. In saying this I do not wish to suggest

that this disease is a myelitis secondary to meningitis produced by the presence of organisms in the cerebro-spinal fluid. We frequently see cases of intense meningitis in which there is no evidence of myelitis beyond the general toxic effects of the poison on the ganglion cells and myelin sheaths. In acute ascending myelitis we have a condition closely resembling the morbid process produced experimentally by Homen when he injected organisms into the sciatic nerve or into the substance of the spinal cord. The characteristics common to both the human disease and the experimental results are the scattered irregularity of the lesions, the preference for the white matter, and especially for the posterior columns, the spread of the process in an upward direction along the central cord and meninges, in addition to the essential features of the inflammatory processes. The fact that in many cases of virulent meningitis in which the causative organism can be seen in great numbers in the meningeal exudate there is no invasion of the cord itself, suggests that the subarachnoid space is not in direct communication with the intramedullary lymphatic system, although both the meninges and the cord can be infected from the lymphatics of the spinal nerves and spinal roots. The anatomical basis for this pathological fact is not, as far as I know, clearly understood.

The theory of lymphatic infection explains why in acute ascending myelitis the perivascular infiltration is not a general one as it is in acute poliomyelitis, and why the foci of inflammation are localised in such a way as one would expect from the lodgment of micro-organisms here and there in the tissues. In other words, the incidence of the disease is independent of the blood-supply except in so far as the vessels penetrating the cord carry with them lymphatic channels. Some further support is offered in my case by the presence of the ring of fatty change in the pia mater, epispinal space, and cord periphery, indicating, as it does, that the earliest changes took place in this part of the lymphatic system and thence spread along the lymphatics of the radial vessels into the interior of the cord. Unfortunately this point of view was not in my mind when I examined the case anatomically. If it had been I should have studied especially the lymphatic tracts leading to the central nervous system—those which accompany the spinal nerves. On the other hand, I have had the opportunity of examining carefully a case of secondary infection of the spinal cord with sarcoma, the primary lesion being situated in the kidney.

This case suggested very forcibly the possibility of infection of the spinal cord from the organs of the abdomen and thorax and is confirmatory of the experimental work of Homen, in spite of the fact that a malignant neoplasm and not a bacterium was the infective agent. It is, on the other hand, conceivable that in some instances the infection of the cord may be, in the first place, through the blood stream and the spread of the morbid process within the cord carried on by the intramedullary and meningeal lymphatics.

The question of the diagnosis of this disease need not detain us long. Sufficiently careful clinical examination should prevent any confusion with acute poliomyelitis or Landry's paralysis on account of the presence of more or less complete sensory loss climbing up the segmental ladder of the body rung by rung, hand in hand with the paralytic phenomena, and on account of the early affection of the sphincters. In a similar way the root distribution of the anæsthesia and paralysis will suffice to distinguish acute ascending myelitis from acute toxic polyneuritis, in which disease the anæsthesia is rarely so complete and is usually confined to the stocking and glove areas. It is obvious that the prognosis in acute ascending myelitis must always be exceedingly grave and it is highly probable that the great majority of cases end fatally.

The conclusions arrived at in connexion with acute ascending myelitis are as follows:—

1. A group of cases, which have the same clinical picture, but which may arise either spontaneously or as a secondary complication in other infective conditions, deserves the name acute ascending myelitis.

2. These cases are characterised from the clinical point of view by an acute ascending paralysis associated with marked loss of cutaneous and deep sensibility of all kinds and with loss of sphincter control, and anatomically by an acute inflammation of the spinal cord, affecting both the white and grey matter, beginning generally in the lower dorsal or lumbar regions and spreading upwards to the medulla.

3. Both on experimental and clinico-pathological grounds

there is evidence to support the view that the inflammation is due to an infection of the lymphatic system of the spinal cord; in other words the disease is a spinal lymphangitis.

4. The condition is not a specific one and may be due to the action of various micro-organisms. There is no particular age incidence nor is there any instance of an epidemic tendency.

LANDRY'S PARALYSIS.

The first question I have to put is this: Is there a distinct morbid condition deserving of the name Landry's paralysis? Probably Landry's paralysis is the best-abused name in medical literature and more cases have been described under that heading with no justification than under any other title. Every form of paralysis which has been rapid and which has happened to begin in the lower extremities and extend upwards has been called Landry's paralysis, whether the morbid changes in the cord have been gross or insignificant. Nearly as many fatal cases of acute poliomyelitis in the adult have been published under the name Landry's paralysis as under their proper title.

Much the same may be said of the efforts which have been made to force all cases of Landry's paralysis into the category of peripheral neuritis, but for this course there are much stronger grounds. It is quite evident that not every case of acute ascending paralysis should be called Landry's paralysis and therefore the important point to decide is whether there are sufficient other clinical and pathological data to form a special disease. To my mind it does not matter, nor shall we ever know, what was the actual disease from which the cases described by Landry suffered. It is sufficient that he called our attention to a class of case in which the symptoms were those of a rapidly spreading motor paralysis without atrophy and without sensory or sphincter disturbances and in which he was unable by the methods at his disposal to detect anatomical changes. Does this class of case exist now? The answer to this question is in the positive if we make allowance for our improved histological methods, and yet remember that Landry would certainly have been able to detect the changes of acute poliomyelitis or of any other acute inflammatory process. The advantages we have over Landry consist chiefly in being able to examine nerve cells by the Nissl and nerve fibres by the Marchi methods.

I have had the opportunity of examining clinically and anatomically three cases of acute motor paralysis presenting the symptom-complex described by Landry and in each case there were identical pathological findings, all of which were slight and only demonstrable by the methods I have just referred to. Three cases alone are almost sufficient, but there are many others in the literature which may be added for the purpose of establishing a distinct morbid entity. The first case was one which I published in full about four years ago, together with the results of a bacteriological investigation. Of the other two, one was observed before and one after the first, but neither has been previously published. A short account of the clinical history of each is necessary before passing on to their pathological features.

CASE 1.—The patient, a man, aged 33 years, was admitted into the National Hospital for the Paralysed and Epileptic on Dec. 20th, 1902, under the care of Sir William Gowers. The duration of his symptoms extended over 18 days.

CASE 2.—A youth, aged 18 years, was admitted under the care of Dr. James Taylor on March 3rd, 1902. The patient was an engineer's assistant and had never had a day's illness since he began work at 11 years of age. There was no history of alcohol, gonorrhœa, or syphilis. Three weeks before admission he noticed some pain in his back and a feeling of general weakness. Four or five days later he experienced definite paresthesia in his legs, falling down in attempting to ascend some steps. The trouble increased and in the course of a day or two he was obliged to take to bed. A week later his arms began to lose power, respiration became affected, and regurgitation of fluid through his nose took place on drinking. On admission the patient looked strong and healthy as he lay in bed and his mind was perfectly clear. The motor functions of the cranial nerves were in no case lost, but there was slight general weakness of the facial, mandibular, and palatal muscles. On the other hand, the tongue and eye movements were of normal strength and range. The neck muscles were distinctly paretic and the patient was unable to raise his head. All the arm movements were feeble, but none absent; he could not raise his arm or forearm against gravity, but could extend and flex his wrists and fingers against the same

force. Full extension of the terminal phalanges was impossible and the movements carried out by the thenar and interosseal muscles were extremely feeble. On the whole the proximal parts of the limb were affected more than the peripheral, but the condition was very generalised. The whole of the thoracic and abdominal musculature was morbidly paretic, respiration being partly costal, partly diaphragmatic, and much embarrassed. The respiratory rate was 28 per minute. The legs were still more paralysed; slight flexion and extension of toes were possible, but no movements at the ankles or knees. The patient could just shift the thighs but was unable to lift them. The electrical reactions were normal everywhere. On the sensory side no impairment of cutaneous sensibility could be detected, but the patient experienced some tingling and pricking in the hands, feet, and legs. There was some tenderness of the calves and arms on pressure. All deep and superficial reflexes were absent and examination of the internal viscera revealed no abnormality. The sphincters acted normally. Death took place within 48 hours of his admission from respiratory failure, the temperature never rising above normal until just before death, when it reached 99.4° F. The duration of the symptoms was about three weeks.

CASE 3.—A man, aged 41 years, was admitted into the National Hospital for the Paralysed and Epileptic on May 27th, 1903, under the care of Dr. J. S. Collier. The patient had enjoyed good health with the exception of an attack of rheumatic fever at 22 years and a doubtful history of syphilis. On May 22nd he noticed some tingling in his hands and feet. On the evening of the 23rd he was unable to lift a glass to his lips and the following morning he was conscious of weakness in all four extremities. On the day of admission he had become unable to stand or even to sit up and his arms were useless. He complained of some painful cramps in his paralysed limbs and some dull pain in the small of the back. He had no numbness and no sphincter trouble. On examination the patient proved to be a large, muscular, robust man, quite unable to help himself in any way. His temperature was 99° F., the pulse was 112, and the respirations were 28. There was complete flaccid palsy of both the upper and lower extremities and of the trunk muscles; raising the head from the pillow was just possible. Respiration was very difficult, both intercostals and diaphragm being extremely weak. Coughing was impossible, articulation was imperfect, and the voice was feeble. Although he had considerable difficulty in masticating his swallowing was fairly good. There were no other signs in the cranial nerves. Cutaneous sensibility was perfect everywhere and no tenderness was present in the muscles or on pressure over the spine. All deep and superficial reflexes, including the jaw-jerk, were absent. The electrical reactions were normal except that the response in the legs was perhaps rather slow. The sphincters were under normal control. The respiratory difficulty increased rapidly and the patient died at 6 o'clock the following morning, the temperature never rising above 100.4°. In this case the duration of the disease was only six days.

The results of the post-mortem examination of the three cases may be taken together as they closely resemble one another. The points of interest are the following.

1. No evidence of disease was present in the nervous system to the naked eye, except general vascular engorgement. It is particularly to be noted that the cord was firm in consistence throughout in all cases.

2. The only cell change was that seen in the spinal cord by the Nissl method, and in no instance was it extensive. The first case presented a considerable number of cells, both of the anterior horns and Clarke's column, with early pericentral chromatolysis and a few with complete, or nearly complete, loss of chromatin granules and concentration of nuclei, especially in the lumbar region. In both the other cases a similar condition was met with, but of even slighter degree in the third. With regard to this cell change I would remind you that I found nothing of the kind in the spinal cord of any of the general toxic cases which I mentioned in my first lecture.

3. By the Marchi method the nerve fibres in the cord and in the peripheral nerves showed the fine scattered droplets of fat to which I referred in my first lecture. I pointed out then that this form of myelin degeneration differed from true Wallerian toxic degeneration in the fact that the droplets were smaller and discontinuous, generally single or

only two or three together, and was not necessarily associated with any loss of function on the part of the axis cylinders. Having found a similar appearance in all sorts of toxic conditions without paralysis I am not inclined to regard it in Landry's paralysis as indicative of anything more than the toxic state undoubtedly present. When I published the first case some years ago I attached more importance to this fatty change than I do at the present time. Fatty change was also demonstrated by the Marchi method in some of the leg muscles in two out of the three cases, and the cells of the spinal cord probably contained rather an excess of fat as seen by the same method.

4. There was no definite evidence of neuroglial or vessel changes. In the first case, in one part of the cervical region a very slight perivascular infiltration was seen around one of the branches of the central artery, but this was entirely exceptional. Examination of the neuroglial tissue in sections of the first case, stained by methyl violet, showed that many of the neuroglial nuclei were surrounded by rather more protoplasm than normal but there was nothing to suggest active proliferation of these elements. A certain number of amylaceous bodies was present in each instance.

If we subtract from the morbid changes I have described the diffuse fatty myelin degeneration in the white columns of the cord and in the peripheral nerves, which is common to acute toxic states of various kinds, we have left practically nothing but the ganglion-cell changes in the spinal cord. The latter are not of great degree or of extensive distribution but must be regarded as important on account of their absence in cases of "non-nervous" toxæmia. There is justification, then, if histological data are to count for anything, for believing that the poison at work in these cases exerted its chief influence on the ganglion cells and that the changes thus induced form the only obvious morbid anatomy of the disease. With this we must rest content, noting, by the way, that histological change does not indicate truthfully in this instance, as in many others, the depth of functional disturbance.

The cases that I have just described are not by any means the only instances in the literature in which the clinical symptoms of Landry's paralysis have been associated with slight cell changes and diffuse fatty myelin degeneration. Moreover, the cases which were examined before the days of the Nissl and Marchi methods and which presented no anatomical changes may well be allowed a place in the same category.

BACTERIOLOGY.

It is usual, in discussing the bacteriology of Landry's paralysis, to drag into the discussion all the cases of acute spinal paralysis in which bacteria have been detected in the spinal cord, the meninges, or the blood. I have done this myself in a previous paper, but now I shall confine myself to those examples of the disease which may properly be placed by the side of the three cases I have just described, cases in which there is nothing to suggest a bacterial invasion of the spinal tissues with inflammatory reaction. In the first place I will recapitulate briefly the results of my bacteriological investigation of Case 1. 1. A micrococcus was isolated in pure culture from the blood of the patient after death. 2. An organism, indistinguishable from that which was cultivated, was found in large numbers in the external part of the spinal theca. 3. A subdural injection of the cultivated coccus into a rabbit produced after some days a rapidly spreading palsy. 4. The same organism was discovered in the theca of the rabbit and isolated in pure culture from its blood. 5. In neither the patient nor the rabbit was the organism to be demonstrated in the spinal cord or the pia-arachnoid, and in neither case were there inflammatory reactions in those tissues. In my second and third cases all efforts to find bacteria, either by culture or by staining of films and sections, were without result.

The same lack of success has attended the bacteriological examination of most cases of Landry's paralysis which have not shown evidence of being in reality cases of inflammatory myelitis. Roger and Josué recorded a case of acute ascending paralysis without any known etiological factor in which they found toxic changes in the cells of the lumbar enlargement. Sections stained for bacteria did not demonstrate the presence of any organisms but cultivations from the heart blood produced a diplococcus resembling the pneumococcus. Injections of the coccus into a mouse did not prove fatal. A rabbit submitted to the same experiment died at the end of 21 days with symptoms of paraplegia and the

diplococcus was recovered from its blood. Macnamara and Bernstein isolated from the blood and cerebro-spinal fluid of a case of Landry's paralysis during life a micrococcus most frequently seen in tetrad groups, staining by Gram and growing anaerobically on gelatin without liquefaction. They considered that it bore some resemblance to the organism which I had found but were unable to obtain any positive results from experimental inoculation. The latter might be due, according to their statement, to the fact that only sub-cultures were used for injection in animals. This case made a complete recovery. These are, in my opinion, the only positive observations which are of value in regard to the bacteriology of the particular class of case under consideration. There is little to go on, at present, but it is clear that the blood should be investigated as well as the cerebro-spinal fluid during life, and that other tissues besides the central nervous system will need more careful search after death. The possibility of the extradural vascular tissues forming a hiding place is one to which I have already drawn attention, but my one and only opportunity for confirming this was unsuccessful.

With your permission I will leave the subject of Landry's paralysis at this point for the moment and reserve the discussion of its pathogenesis, diagnosis, and prognosis until I have said something about acute toxic polyneuritis.

ACUTE TOXIC POLYNEURITIS.

The subject of toxic polyneuritis is a very large one and I have no time or desire to deal with it as a whole. There are, however, cases belonging to this group in which the acute onset, the widespread palsy, and the lack of any marked anaesthesia produce a striking clinical resemblance to cases of Landry's paralysis, or even in some instances to acute poliomyelitis. It is with these cases I have now to do. The question of title again presents itself and there is a general feeling that this group might well have a distinctive name if only a suitable one could be found. "Toxic degeneration of the lower motor neuron" is too long, and "motor neuritis" is open to popular if not medico-legal misinterpretation. It is perhaps better to postpone the classification of the various forms of toxic polyneuritis until we know more about the agents concerned in their causation. The only object I have in bringing these cases forward is to endeavour to settle the question as to their identity or non-identity with Landry's paralysis. The solution of the problem is, I believe, of great practical moment in that it involves the all-important question of prognosis in individual instances.

CASE 1.—A man, aged 25 years, was admitted into the Royal Free Hospital on August 8th, 1903, under the care of Dr. J. W. Carr. His previous health had been good, with the exception of a syphilitic infection three years before, for which he had been well treated. He had always been abstemious as regards alcohol and had been a total abstainer for four months. No other etiological factor could be discovered to account for his disease. About six weeks before admission he had suffered from some vague pains called rheumatic from which he recovered. On August 6th he did not feel well, was easily exhausted and faint, and experienced some tingling in his hands and feet and some pains in his toes while walking. In the course of the next few days he rapidly developed paresis in all four limbs and to a certain extent in his trunk muscles, although respiration was never embarrassed. On examination this paresis was found to be slightly more marked on his left than on his right side and to affect the peripheral more than the proximal parts of the extremities. There was also well-marked loss of power in the muscles supplied by both facial nerves so that he was unable to shut his eyes firmly or to whistle. There was practically no loss of cutaneous sensibility anywhere but the limb muscles were distinctly tender on pressure. The tendon reflexes were abolished and the plantar reflexes of the flexor type. The patient made a somewhat rapid recovery but not without some wasting of the muscles below the knees and elbows, which were slower in regaining power than those of the thighs and upper arms.

CASE 2.—A married woman, aged 34 years, was admitted into the National Hospital for the Paralysed and Epileptic on Jan. 15th, 1904, under the care of Dr. C. E. Beevor. Her previous history was good and as regards alcohol free from suspicion. A fortnight before her troubles began she had suffered from influenza. The onset of her illness was characterised by three days of pain in the back and legs,

followed by sudden development of almost complete loss of power in the lower extremities. A week later her arms and face became similarly affected. On admission she was found to have facial diplegia of the peripheral type affecting both the orbicularis palpebrarum and oris, as well as the other muscles supplied by the seventh nerves. The function of the other cranial nerves was normal. All four extremities were markedly paretic, the peripheral muscles suffering more severely than the proximal. There was no sensory loss but both nerves and muscles were tender on pressure. All the deep reflexes were absent, the abdominal present, and the plantar of the flexor type. Slight but temporary difficulty in micturition was also noted. The patient made a fairly rapid and complete recovery.

CASE 3.—A man, aged 26 years, was admitted into the National Hospital for the Paralysed and Epileptic on March 9th, 1897, under the care of Dr. J. A. Ormerod. His circumstances were good, his previous health was satisfactory except for gonorrhoea two years before, and his habits were temperate. Eight weeks before admission the patient fell off his bicycle and cut his hand, the wound healing in a fortnight's time. Six weeks before admission he noticed numbness of both hands and a week later numbness of both feet. This was immediately followed by weakness of all four extremities. On examination his cranial nerves were tested and found to be normal. The movements of the head and neck were well performed. All the muscles of the arms were feeble but none of them completely paralysed. Respiration was carried on by the intercostal muscles, the diaphragm being entirely out of action. The abdominal muscles were moderately affected. There was great weakness of the legs, especially of ankle movements. The knee movements were affected more than those of the hips. Cutaneous sensibility was slightly diminished over the glove and stocking areas and the muscles of the limbs, especially of the forearms, were tender on pressure. None of the deep reflexes were obtained, the abdominal reflexes were brisk, and there was slight difficulty in emptying the bladder in the supine position. This patient made a rapid and good recovery but reappeared at the hospital six years later in a precisely similar condition which had again begun about six weeks before his admission. The paralysis had been ushered in with numbness in hands and feet and had attacked the peripheral more than the proximal limb muscles. Speaking generally, the patient was worse than during his first attack and suffered from slight impairment of phonation and deglutition but his restoration to health was both rapid and complete.

Such cases as these could easily be multiplied, but the three chosen will serve to illustrate the class with which I am dealing.

The opportunities for studying the morbid anatomy of this condition are not so numerous on account of its more favourable course, but there are instances in which a fatal termination has occurred and in which lesions limited to the lower motor or to the lower motor and sensory neurons have been found. Apart from cases complicated with a history of alcohol, the only post-mortem examination I have made bearing on this subject was that on a case already published by Stanley Barnes in his paper on Toxic Degeneration of the Lower Motor Neurons. In this patient, a woman, 34 years of age, the history recorded two attacks of peripheral neuritis. The first followed an attack of mumps, about 14 months before her death, and affected the lower extremities only. The second occurred two months later and involved all four extremities. The second attack left her with almost complete atrophic palsy of the feet and hands, the proximal muscles of the limbs recovering. About a year later she became suddenly ill and in the course of a few days developed fresh paresis which caused her death within 24 to 48 hours from respiratory failure. In this case I found, in addition to the evidence of the old lesion, acute toxic changes in the anterior horn cells of the cervical and lumbar enlargements, although no recent changes were present in the peripheral nerves, a fact which is not to be wondered at when it is remembered that the paralytic phenomena of the third attack had hardly lasted long enough for demonstrable changes by the Marchi method. There can be little doubt that this patient succumbed to the third attack of some toxic condition implicating the lower motor neurons. The same case illustrates the physical condition of a patient who has suffered from a severe attack of this disease by the presence of an almost complete atrophic palsy of the peripheral parts of the limbs.

Let me contrast this with a case which has been recently under the care of Dr. James Taylor at the National Hospital for the Paralyzed and Epileptic. A man, aged 26 years, in the course of two or three weeks developed marked paresis of all the muscles of his limbs and trunk, beginning in the legs and spreading upwards. A similar paresis affected the facial muscles and those of deglutition. It was remarked that the movements at the hips and shoulders were as weak as those at the ankles and wrists; cutaneous sensibility was practically normal and there was no definite tenderness of any muscles on pressure. In the course of his recovery, which took place gradually and completely during the two months he was in hospital, the gain of power was steady and equal over the whole of the musculature and no local atrophy was present at any time. Dr. Taylor regards the case as one of mild Landry's paralysis—an opinion with which I am in complete accord.

While it is clear that, both in the cases which I have described under the heading of Landry's paralysis and in those to which I have referred as examples of toxic polyneuritis, the incidence of the toxic agent is chiefly upon the lower motor neurons, there is undoubted evidence from the clinical point of view that the two conditions are not identical. In both groups all the muscles of the bodies may be involved, but in Landry's paralysis it is the rule to find the paralysis evenly and generally distributed, in toxic polyneuritis to detect a more pronounced affection of the limbs and especially of their peripheral parts, and in some cases of the facial nerve. There are other points of diagnostic value to which I shall refer presently. In the meanwhile it will be of interest to consider whether there are any pathogenetic facts which will throw light on the difference between these two clinical pictures. Taking the case of the toxic polyneuritis first, it is only natural to suppose that the poison at work is carried by the blood and that the parts innervated by the grey matter of the cervical and lumbar enlargements suffer more than those in similar connexion with the dorsal region for reasons which I have already given in discussing the general principles of blood-supply. At the same time the whole of each lower motor neuron, including both the cell and its axon, is exposed to the poison in the general circulation and in these circumstances the particular affection of the long processes to the periphery of the limbs has an explanation offering some degree of probability. This applies to all forms of polyneuritis, whether the poison is of autogenous or exogenous origin, so long as it is carried by the blood.

Is it possible that the lower motor neurons are affected in a different way in cases of Landry's paralysis? Marinesco in his experimental inoculations of various forms of bacteria into the subarachnoid space of animals found that in some cases the organisms invaded the arachnoid space and the lymphatic spaces around the vessels without producing vascular or leucocytic reaction, at the same time secreting toxins which affected the elements of the spinal tissues. This fact is one of great importance because it would seem to show that certain bacteria or their toxins present in the lymphatic system of the cord can produce toxic effects without inflammatory reaction. In my first case of Landry's paralysis I found the cocci in the extradural tissues and it is quite conceivable that infection either by the cocci or by their toxins could take place from those tissues into the extradural and intramedullary lymphatics. From the absence of actual organisms in the spinal tissues in most of these cases it is probable that the toxins play the most important part in this infection. Allowing for a moment that this theoretical process can take place it must be granted that an explanation of the gradual, ascending, step by step, involvement of the central nervous system is provided, and one which makes the more progressive and even distribution of the palsies more readily understood. This theory does not necessarily pre-suppose that the blood is free from the responsible organism nor that the extradural tissue is its only resting place, but it suggests that there may be places where the bacteria may find suitable lodgment for the purposes of multiplication and whence they may pour their toxin into the spinal lymphatic system.

DIAGNOSIS.

I must now hasten to pass from what may well be considered the realms of theory to the more practical results of my own observation on the clinical characteristics which distinguish the various morbid conditions I have dealt with. In doing this I will leave acute ascending myelitis out of

consideration for the reason that its sensory and sphincter disturbances are sufficient to distinguish it from any of the other three diseases. The two most important problems are the differentiation of acute poliomyelitis from Landry's paralysis and that of the latter condition from acute toxic polyneuritis. The mistake of calling a case of acute and widespread poliomyelitis one of Landry's paralysis has been made so often and by such good observers that I feel no shame in admitting that I have erred in the same way. The error, however, has led me to consider whether there are clinical features in the early stages of these diseases, at which time the only possibility of confusion arises, characteristic enough to prove efficient guides. The following points must not be taken as of universal and unexceptional application, but as general principles:—

1. *The constitutional symptoms* in the severe cases of acute poliomyelitis are more marked than those in Landry's paralysis, the range of temperature is higher, often reaching 102°–104°, the malaise and anorexia are more profound, and vomiting and disturbance of the alimentary canal are more frequent. In children convulsions are often associated with the former ailment.

2. *Sensory phenomena*.—In Landry's paralysis there may be, and often is, complaint of pain in the back, of sensations of numbness or tingling in the extremities before and during the onset of paralysis. The only sensation complained of in the paralyzed limbs is that of discomfort or of cramps arising, partly at any rate, from their immobility; they may be handled without giving rise to anything more than slight tenderness on deep muscular pressure. In acute poliomyelitis the pains complained of are more urgent and affect not only the back, head, and neck, but frequently the limbs as well. The paresthesia may be present but a prominent feature is the pain, sometimes very severe, elicited by passive movements of the affected extremities.

3. *Motor phenomena*.—In both diseases paralysis is flaccid and may be general. The escape of a single muscle or of a group of muscles in a region where all the others are affected or a marked asymmetry in the condition of corresponding muscles on the two sides of the body are suggestive of acute poliomyelitis rather than of Landry's paralysis. Within a few days or a week of the onset in cases of acute poliomyelitis, if death has not occurred it is usual to find rapid recovery in some parts and early atrophy and electrical changes in others. In Landry's paralysis recovery, if it takes place, is slow and evenly distributed without marked atrophy.

4. In both diseases the sphincters usually escape, the inability to empty the bladder and rectum, which is often a temporary symptom, being due to the impaired abdominal musculature and the position of the patient.

Similar general rules for diagnostic guidance can be drawn in the case of Landry's paralysis and acute toxic polyneuritis.

1. *Constitutional*.—Although the constitutional symptoms in Landry's paralysis may be only of slight severity it is the rule to find some rise of temperature and associated anorexia. Cases of acute toxic neuritis may, on the other hand, often run their course with no corresponding features.

2. *Sensory phenomena*.—I have already referred to those of Landry's paralysis. In acute toxic polyneuritis numbness, pins and needles, and sharp pains are common in the extremities and very marked tenderness of muscles, sometimes of nerves, is the rule. There may or may not be relative anaesthesia in the glove and stocking areas.

3. *Motor phenomena*.—These are very important and can only be properly appreciated by carefully and systematically testing the various groups of muscles in the body. In the first place the limbs are more affected than the trunk and the peripheral parts of the limbs more than the proximal in acute toxic polyneuritis. In the same disease, although many of the trunk muscles may be involved, the most marked incidence is generally upon the diaphragm, in which case respiration becomes entirely costal. Of the cranial nerves those supplying the facial nerves are often picked out and may be the only ones to suffer. Sometimes the palate is also affected. In Landry's paralysis the musculature is affected generally and evenly, the trunk and limbs presenting a degree of paresis which is more or less symmetrical and equal. In cases in which the paralysis first affects the lower extremities it is not uncommon to find these parts most parietic at the time of observation, but the spread of the disease will then be a progressive one in an upward direction and the thoracic muscles may succumb before the diaphragm or both may be

equally weak. When the muscles affected by the cranial nerves are involved deglutition, phonation, articulation, together with the movements of the face and jaws, may be impaired, but the fatal termination generally takes place before any one of these actions is abolished. The condition may be progressive over two, three, or more weeks, and yet be unassociated with any definite local atrophy of muscles, and recovery may take place without its appearance. In acute toxic polyneuritis recovery, even if rapid and good, is usually accompanied by some temporary muscular atrophy and diminished electrical excitability in some of the limb muscles, especially the dorsiflexors of the ankles and the extensors of the wrist and fingers.

4. *Reflexes.*—The deep reflexes are abolished in both diseases in the affected parts. The abdominal reflexes are often retained in acute toxic polyneuritis and nearly always abolished in Landry's paralysis. The plantar reflexes are absent or flexor in type in both instances and the sphincters are only temporarily, if at all, disturbed. In addition, it is interesting to note that relapses and recurrences occur in toxic polyneuritis, although they are, as far as I know, unrecorded in poliomyelitis or Landry's paralysis.

PROGNOSIS.

In acute poliomyelitis the prognosis depends upon the extent of the morbid process with especial relation to the respiratory musculature. In the case published by Greene, Wilson, and Rothrock artificial respiration was carried on for 41 days before sudden death brought a "merciful solution to a hopeless problem." If the patient survives the first few days without grave respiratory difficulty the prognosis may be regarded as favourable. The issue in cases of acute ascending myelitis I have already discussed and I need only emphasise here the gravity of the outlook. Landry's paralysis must also be regarded as a particularly fatal disease and in this respect presents a distinct contrast to acute toxic polyneuritis, in which a favourable termination may be generally anticipated.

In conclusion, may I venture to hope that I have provided some evidence that there are four distinct kinds of acute paralysis, that there are clinical and anatomical points by which they may be differentiated, and finally, but by no means conclusively, that acute poliomyelitis is an acute specific fever in which the nervous system is attacked through the circulation, acute ascending myelitis a spinal lymphangitis, Landry's paralysis possibly a species of spinal lymphatic intoxication, and acute toxic polyneuritis a toxæmia producing a parenchymatous degeneration of the lower motor neurons?

THE TREATMENT OF ACUTE FAILURE OF THE HEART.¹

BY CHARLES BOLTON, M.D. LOND., M.R.C.P. LOND.,
ASSISTANT PHYSICIAN TO UNIVERSITY COLLEGE HOSPITAL.

IN selecting my subject I have been guided by the two following considerations: first, the importance of acute failure of the heart, which terminates life in such a vast number of diseases; and secondly, the fact that it is the medical man in general practice who is brought most intimately into relationship with this condition, and therefore fittingly qualified to discuss the subject and relate what his personal experience has been.

With regard to the manner in which acute heart failure is brought about two distinct classes of cases must be recognised. 1. The failure may be due to some organic condition affecting the heart, the blood, or the blood-vessels, and therefore initiated in a purely mechanical manner. 2. It may be the result of some nervous disturbance such as occurs in sudden death from vagus inhibition or in cases of tachycardia. The time-limits of this paper will allow me to deal with the first class only. It includes the vast majority of cases and is therefore of greater importance, more especially as the heart condition resulting from nervous disturbance does not so readily yield to treatment.

As a preliminary step I will first indicate the various pathological conditions with which we have to deal. The heart, as you know, has two functions: (1) that of a force pump, by means of which the blood is pumped during

systole from the veins where the pressure is low into the arteries where the pressure is high; and (2) that of a suction pump, by means of which the ventricles are filled with blood during diastole. As a matter of fact, the heart has very little suction power at all, its cavities being filled chiefly because the pressure in the large veins is greater than that in the pericardium. Acute heart failure is therefore brought about by any condition interfering with the emptying of its cavities during systole or the filling of its cavities during diastole.

1. Interference with the heart in its capacity as a force pump may be brought about in two ways: either (a) by deficiency in its muscular power or (b) by an increased resistance to the output of blood. (a) Deficiency in the muscular power of the heart occurs in acute degeneration of its muscular fibres resulting from the action of a poison. Diphtheria, typhoid fever, pneumonia, rheumatism, influenza, and alcoholic poisoning are all examples of diseases leading to acute degeneration of the heart. There is evidence that alcohol may act as a direct depressant to the muscular tissue of the heart, without degeneration of the fibres having been previously produced. When the blood-supply of the heart is interfered with rapid failure may be brought about as illustrated by that resulting from coronary occlusion. Finally, acute failure may result in cases of chronic muscular degeneration, brought about in all the various ways with which you are quite familiar. Probably in a number of these cases implication of the auriculo-ventricular bundle is at the bottom of the mischief. (b) An increase of the normal resistance to the output of blood leads to an increase of work to be done. The heart may be diseased or healthy and therefore failure to respond to the increased amount of work presented to it may be brought about in some cases quite easily and in others only if the increased resistance is very excessive. Such an increase of work results from excessively high pressure either in the systemic or pulmonary blood-vessels. Acute Bright's disease is a good example of a disease producing a more or less rapid rise of arterial blood pressure and in this disease acute failure of the left heart may result. Everyone is familiar with acute failure of the right ventricle resulting from obstruction in the pulmonary circulation especially in mitral stenosis, bronchitis and emphysema, and pneumonia. It is also held by some observers, notably Professor Kronecker of Berne, that the diminished barometric pressure of high altitudes gives rise to acute heart failure, especially when some disease of the heart or arteries is already present, by engorging the lungs with blood and thus throwing a strain upon the right ventricle.

2. *The diastolic filling of the heart* may be affected in one of two directions, the diastolic blood quantum being either increased or diminished. Each of these conditions leads to a rapid failure of the muscular tissue of the ventricles. I will give two examples of excessive filling of the cardiac cavities. Muscular exertion empties the veins towards the heart and distends the right ventricle, this effect being exaggerated by the deep respiratory efforts. The vaso-dilatation and low arterial blood pressure of prolonged exertion also aids in keeping up the distension of the veins. The aortic blood pressure, on the contrary, is raised by a sudden effort and as you know may lead to rupture of an aortic valve with regurgitation of blood and resulting acute dilatation of the left ventricle. The diastolic blood quantum is diminished by any condition which raises the intrathoracic pressure, the best example being pericardial effusion. A much more serious event is hæmorrhage into the pericardium, which rapidly leads to death by increasing the pressure in that cavity so that the heart is unable to fill. In this case the pericardium has not the time to stretch as it has in cases of pericardial effusion, so that in the latter disease death brought about in this way is comparatively rare. Finally, a diminution in the total amount of blood, as seen in hæmorrhage, and vaso-motor paralysis occurring in the shock, both produce acute heart failure owing to the diminished filling of the cavities during diastole and also through muscular weakness resulting from deficient circulation in the coronary vessels.

Cardiac thrombosis and embolism probably bring about heart failure in several of the various ways which I have already mentioned. They may interfere with both the filling and the emptying of the heart and at the same time failure in the muscular power of the ventricles is generally present.

I shall commence with the treatment of deficiency in the

¹ A paper read before the North London Medical and Chirurgical Society on Jan. 17th, 1907.

muscular power of the heart resulting from acute disease. This class includes undoubtedly the largest number of cases which have to be treated, and in each disease the muscular weakness is brought about by the direct action of some poison on the muscular fibres, and probably in many cases the high fever is also responsible to some extent. We are, therefore, dealing with an acute degeneration of the heart. The old treatment consisted in stimulating the heart by means of alcohol, in the hope of keeping this organ in action until the disease had passed away. Acute degeneration of the muscular tissue was not then so well recognised as at the present day, and there is no doubt that many of those patients died from exhaustion of the heart as a result of overstimulation. Stimulation also increases the work of the heart, and this is precisely the state of affairs which we wish to avoid. At the present day we recognise three indications for the treatment of this condition: (1) to prevent, to stop, or to diminish the degenerative process; (2) to diminish the work of the degenerate heart; and (3) to stimulate the heart only over very short periods when fatal syncope is threatened.

There is only one acute disease in which we can successfully accomplish these ends, and that disease is diphtheria. Acute diphtheritic poisoning kills the patient from the direct action of the toxin giving rise to fatty degeneration of the heart; there is also acute degeneration of the nucleus of the vagus, causing slowness and irregularity of the heart beat and a tendency to sudden syncope. This degenerative process can be arrested or prevented, if not already present, by the timely administration of antitoxin. The efficiency of action of the antitoxin depends upon the stage of the disease at which it is administered and upon the size of the dose. The importance of the antitoxic treatment of diphtheria is so very great that it cannot be reiterated too often. If antitoxin is administered on the first day of the disease, a circumstance only possible when the patient contracts the disease in a hospital, the mortality is only $\frac{1}{2}$ per cent., and this mortality increases in exact proportion to the delay in the administration of antitoxin. After the fifth day antitoxin is unable to produce any reduction of the mortality because by that time advanced degeneration has already occurred and if it is sufficient in amount to kill the patient antitoxin is quite powerless. Therefore not an hour's delay must be allowed to occur before it is administered. If antitoxin is given to an animal already poisoned by diphtheria toxin large doses are necessary to save the animal. If given at the same time as the toxin comparatively small amounts are sufficient. Therefore the dose of antitoxin administered to a diphtheria patient must be very large and clinical experience substantiates this statement. In a mild case from 4000 to 6000 units must be at once given; in a severe case from 12,000 to 24,000 units, and if the membrane shows signs of spreading the dose should be repeated on the following day. Larger doses than this are probably of no use.

The second point—namely, to diminish the work of the heart—is of the utmost importance in diphtheria, and this is accomplished by rest, both physical and mental. Vomiting, jumping up suddenly in bed, mental excitement or shock, respiratory paralysis, getting up too early in the course of the disease, will all induce heart failure and may lead to sudden death. This effect of strain in bringing out a latent weakness of the heart may be seen at any stage of the disease. Strict confinement to bed in all cases is absolutely necessary. As the pulse varies from hour to hour it should be examined frequently to detect the first sign of irregularity. A slow, irregular pulse is a very fatal sign. When such irregularity is detected, especially if at the same time the heart shows the physical signs of dilatation, the greatest care should be exercised in the nursing of the patient. The head should be kept low and the patient on no account allowed to sit up. He should be disturbed as little as possible and the nurse instructed to be very careful in syringing or making applications to the throat, as the patient may struggle and become very exhausted during the treatment. Vomiting throws a strain upon the heart and therefore caution must be exercised in feeding the patient. If vomiting is present rectal feeding should be resorted to, as no drugs have any influence upon this symptom when once it is present. A consideration of the length of time a patient should be detained in bed is important. However mild the case

appears to be, strict confinement to bed for three weeks is necessary, whether the pulse becomes irregular or not. The patient may then sit up for an hour or two during the day and at the end of a week will be able to walk about. If this exertion brings out a latent heart weakness the patient must be at once put back to bed. The signs of dilatation of the heart and irregularity of the pulse may last for eight weeks or more. Sudden death after the third month has not been observed; therefore, if the pulse is still irregular at this late period of the disease the patient may commence sitting up. Paralysis of the respiratory muscles throws a strain upon the heart by impeding the diastolic filling of that organ, by leading to obstruction of the pulmonary circulation, and by the collection of mucus in the air passages which cannot be expectorated. The heart muscle, already degenerate, is further affected by the chronic asphyxia induced. No direct treatment for this condition can be adopted but the useful expedient of raising the foot of the bed by blocks may be adopted. By this procedure the lungs are drained and the pharynx kept free from saliva, which causes asphyxial attacks by its entrance into the larynx. Belladonna may be given to diminish the secretion. The use of cardiac stimulants and tonics finds very little place in the treatment of acute fatty degeneration of the heart. It must also be remembered that the slow pulse indicates vagus irritation and therefore when this sign is present strychnine and digitalis are contra-indicated. Belladonna, which paralyses the terminations of the vagus in the heart, may be given and occasionally proves useful. Alcohol, which reflexly stimulates the heart, after absorption depresses the muscular tissue from the beginning and therefore is useless for prolonged stimulation in any form of cardiac degeneration. Its use is needed when an attack of sudden syncope occurs. Later in the disease, when the heart fails as the result of strain, the pulse is usually rapid. Strychnine and digitalis may now be given, because they slow the heart and, so to speak, put the brake on, thereby resting that organ. Digitalis in addition directly acts upon the muscle but strychnine does not. The application of heat and counter irritation to the præcordium is sometimes useful, especially when the patient is vomiting.

The acute cardiac degeneration occurring in typhoid fever is due to the direct action of some toxin upon the heart muscle and also to the prolonged fever. Unfortunately, we cannot prevent the degeneration by any antitoxin, as in the case of diphtheria, but we can act upon the fever. Cardiac degeneration, fortunately, is by no means so common in typhoid fever as in diphtheria. It usually shows itself clinically during the third or fourth week of the disease and is especially apt to supervene in those cases with very high fever. The pulse increases in rapidity and becomes very small and compressible and sometimes irregular. The first sound of the heart is short and the sounds are spaced. The impulse may also be displaced to the left. Systematic cold bathing, in addition to its beneficial effects on other systems, prevents heart failure in two ways. Firstly, it produces a lower range of temperature than would otherwise be present; and secondly, it acts as a tonic to the cardiovascular system as in health.

The limits of time prevent my entering into the details of the bath treatment. By this treatment the progressive increase in pulse frequency is not so often seen in typhoid fever; neither does it become so small and compressible. Systematic bathing renders less frequent the complications and modes of death dependent on circulatory failure and the mortality from these is considerably reduced. As in the case of the treatment of diphtheria by antitoxin, so in the treatment of typhoid fever by the cold bath, time is of the greatest importance. The treatment should be commenced at the earliest possible date.

In speaking of diphtheria we have seen the great importance of absolute rest, especially as the patients often feel quite well and resent the confinement to bed. The same applies to typhoid fever; however, in this condition rest is necessarily enforced because the heart failure occurs just at the very time when the patient is in his most helpless condition. Syncope is not so much to be feared as in diphtheria and does not occur during convalescence. Prolonged rest in bed after the temperature has dropped is therefore not so essential. Stimulants are usually not needed when the cold bath treatment is employed. They are, however, required if the case comes under observation late and heart failure has already appeared. In these cases it is dangerous to use very cold

³ Bolton: The Pathological Changes in the Medulla Oblongata in Acute Diphtheritic Toxæmia (Archives of Neurology, L.O. Asylum, vol. II, 1903).

baths. The temperature of the water should not be below 80° F. if the treatment is employed. If heart failure appears in spite of the bathing some stimulation is usually required. Alcohol continuously administered is unsafe owing to its depressing action on the heart muscle and its tendency to give rise to fatty degeneration. It is useful occasionally in an emergency, and also immediately before the administration of a bath. Hypodermics of strychnine are useful in heart failure in typhoid fever because this drug slows the heart and therefore gives it rest. It probably also prevents the tendency to collapse from vaso-motor dilatation. But, as Orle³ has shown, it is of little use unless it causes twitchings and therefore its value is detracted from on this account. Quinine given early is in favour with many. When the pulse rate reaches 120 per minute three grains every three hours should be given day and night. After 24 hours if the pulse is not slowed the dose should be raised to five grains. The drug must be given early. Digitalis is objected to by some because it is said to produce very little effect when the temperature is raised, but in the apyrexial periods the pulse may suddenly fall in frequency. Personally I have not seen any ill effects result from the employment of digitalis in this disease. Ammonia, ether, camphor, and caffeine all have their advocates, but personally I think they are not of much use.

In pneumonia the nerve centres are probably implicated as well as the heart muscle. The cardiac degeneration is brought about by the direct action of some poison, by the fever, and by the partial asphyxia to which the heart is subjected. The acceleration and increase in intensity of the respirations indicate an excitation of the respiratory centre. This is due to the partial asphyxia and probably also to the direct action of the toxic agent, since it occurs in the absence of pain and does not vary in proportion to changes in temperature. The same remarks may be made with regard to the acceleration of the pulse and high systolic blood pressure. Whether an increase in irritability of the heart muscle or an excitation of the cardio-accelerator centre over-riding that of the vagus centre is responsible for the circulatory changes is not certain. The signs of circulatory failure are increase in frequency and smallness of the pulse, some fall in blood pressure, cyanosis and pallor of the face, and coldness of the extremities. The first sound of the heart becomes short and feeble and probably also oedema of the lungs occurs. These symptoms may come on quite rapidly and death occur as early as the third or fourth day or some time after the first or second week. The left ventricle may be chiefly at fault or distension of the right ventricle may occur, with engorgement of the vessels of the neck. This condition of things, as I have before remarked, is referable to degeneration of the cardiac muscle and probably also to over stimulation. The obstruction to the flow of blood through the lungs also plays its part in increasing the work of the right ventricle. No specific serum, which is so valuable in diphtheria in preventing muscular degeneration, has so far been produced in the case of pneumonia. Certain sera have been manufactured but the results of this treatment are too indefinite at present to allow of any reliable deductions being drawn therefrom. Brem⁴ in a recent paper recommends internal hydrotherapy with the object of passing a large amount of fluid through the blood so as to remove, if such a thing be possible, the toxic agent by the kidneys. He claims good results from the internal administration of large quantities of water. It is important to treat the fever and there is no doubt that, as in typhoid fever, the best means to employ for this purpose is external hydrotherapy—e.g., cold sponging or even the cold bath if the fever is high. An ice-bag applied to the affected side not only relieves pain but reduces the fever, and it is a method of treatment of which I can speak very highly. If there is much cyanosis and signs of circulatory failure tepid water or hot sponging should be employed. Delirium and sleeplessness, signs of excitation of the central nervous system, will induce heart failure. In mild cases the bromides or trional are the best drugs to use; when persistent sleeplessness and pain are present a hypodermic injection of one-quarter of a grain of morphine and one-third of a grain of atropine is indicated.

With regard to the use of cardiac stimulants the same remarks may be made as were used in the case of diphtheria, because in pneumonia the central nervous system is also affected. All cardiac stimulants acting upon the central nervous system

such as strychnine are contra-indicated. Strychnine will further stimulate the respiratory centre and respiratory insufficiency may be induced. This objection does not apply to digitalis as it has practically no action upon the respiratory centre. The digitalis group of drugs acts chiefly upon the muscular tissue of the heart and is probably the best class of drugs to employ in circulatory failure in pneumonia. I object to the employment of digitalis in the early stage of diphtheria, because the pulse in this disease is so frequently very slow, but this objection does not hold in the case of pneumonia. Digitalis is regarded by some physicians as a specific for pneumonia. It is not of so much use when the right side of the heart is overloaded with blood, and for this condition the only efficient treatment is bleeding from the jugular vein. Opinions with regard to the administration of alcohol in pneumonia are divided. Some give it freely, others withhold it. Personally I administer alcohol only in cases of the alcoholic type of pneumonia. If used in other cases of pneumonia I think it should be given early when the central nervous system is excited and then it may do good by reducing cerebral excitement or it may be useful in a sudden syncopal attack as a reflex stimulant. Administration of oxygen temporarily relieves the asphyxia and causes a slight fall in the blood pressure. If used I think it should be allowed to play upon the patient's face and not be given through an inhaler.

Acute failure of the heart may result from alcoholic poisoning. Alcohol is a local irritant and therefore reflexly stimulates the heart, after absorption it is a depressant to the cardiac muscular tissue and leads to fatty degeneration. It allays irritability of the central nervous system and reduces delirium, and hence slows the pulse and respiration in acute diseases. It is stated that acute dilatation of the heart may come on after a drinking bout and independently of fatty degeneration. However this may be, dropsy resulting from acute heart failure is common in alcoholic subjects. It may be the left ventricle alone which is found dilated or the physical signs of enlargement of the right side also may be present. There is often no albumin in the urine, the pulse is usually quite regular, and after a few days' rest in bed, together with the administration of digitalis, the dropsy disappears. Sudden occlusion of a coronary artery always leads to death and does not admit of treatment. Acute failure of a heart which is the subject of chronic degeneration either leads to syncopal and anginal attacks or acute dropsy supervenes. In the former case the indications are to lower the blood pressure by nitroglycerine or any nitrite and reflexly to stimulate the heart by alcohol, ether, ammonia, and carminatives. When dropsy is present digitalis should be administered and other treatment for uncompensated heart disease employed. There is much more to be said in this connexion, but I must now pass on to consider those types of acute heart failure dependent upon an increase in the resistance to the output of blood. This increase of work may be presented either to the left ventricle, as is illustrated by acute Bright's disease, or to the right ventricle, as is seen in mitral stenosis or bronchitis and emphysema, in which diseases acute failure of the right ventricle is apt to occur. In acute scarlatinal nephritis hypertension in the systemic circuit is rapidly developed. The heart is healthy to begin with, but in from five to six weeks shows the physical signs of hypertrophy of the left ventricle. In the meantime failure of this side of the heart may occur leading to oedema of the lungs, cyanosis, and a rapid feeble pulse. The right side is also commonly dilated. The first indication for treatment is to lower the arterial tension and to relieve the heart. In order to do this nitroglycerine should be employed and may be used fully combined with venesection and saline purgation. At the same time I employ digitalis to stimulate the heart muscle. Digitalis should not be used for cases of this description unless combined with nitroglycerine, as one of its actions is to raise the blood pressure.

When acute dilatation of the right side of the heart occurs in mitral stenosis or emphysema and bronchitis the treatment is venesection, preferably from the jugular vein. I say from the right side of the heart in this way; whereas, if the basilio vein be used, the blood is abstracted not from the right side of the heart directly but from the whole of the arterial system, and thus indirectly from the right ventricle. Digitalis with diffusible stimulants are not of any use till the patient has been bled.

I now pass to a consideration of acute the heart

³ Orle: An Experimental Research into the Pathology of Shock, 1897, and Blood Pressure in Surgery, 1903.

⁴ Brem: Johns Hopkins Hospital Bulletin, vol. xvi., No. 175, p. 325.

resulting from an increase in the diastolic blood quantum. Here the heart muscle may be perfectly sound and the acute failure results directly from a flooding of the cavities with blood during diastole so that the ventricles become over-distended and are unable to empty. The best example of this condition is found in the effects of strain, including all forms of undue exertion. Sudden severe exertion results in a narrowing of the peripheral arterioles and a rise of systemic blood pressure. The blood pressure, however, soon falls from reflex dilatation of the arteries of the muscles, from increase of the circulation in the skin, and from the sweating produced. The muscular contractions empty the veins in the direction of the heart and the right ventricle is unduly dilated during diastole. The left ventricle secondarily dilates. In prolonged exertion, therefore, the stress is chiefly borne by the right ventricle. When the strain is very sudden the stress is chiefly borne by the left ventricle and an aortic valve may rupture leading to rapid acute dilatation of that cavity. It follows, of course, that the most dangerous results are seen in those who have not had any preliminary training. Functional disorder of the heart, irritable heart, or persistent rapidity for months may follow, but what concerns us now is the acute dilatation of the right ventricle. Cyanosis, dyspnoea, cold perspiration, precordial pain and irregular small pulse ensue, and later mitral regurgitation, albuminuria, and oedema may appear. Autometabolic poisons are formed in violent exertion and may account for the profound insensibility or convulsions which are liable to occur. The first principle in the treatment of such a condition is to relieve the right side of the heart by venesection and the application of leeches. The heart must then be stimulated by counter-irritants and diffusible reflex stimulants such as alcohol, ether, or ammonia. Following this, if the patient recovers a few weeks' complete rest are absolutely necessary, with careful supervision. Later, quiet and interesting exercises such as golf may be indulged in. No alcohol or smoking should be allowed. If dropsy supervene with dilatation of both cavities of the heart digitalis is the drug to employ. When an aortic valve suddenly ruptures there is severe pain in the precordium and faintness, with irregular pulse and possibly hæmoptysis. Drugs are not of much value here and the only good treatment consists in absolute rest and the administration of morphine. Later, if the patient survives, the pulse develops the characters of aortic regurgitation. Cardiac thrombosis leads to acute dilatation of the heart, the result being violent anginal pains, with cyanosis and all the other signs of acute failure. The best treatment in cases of this description is to inject morphine subcutaneously.

According to Professor Kronecker of Berne² the effect of the fall of barometric pressure occurring in mountainous districts is to bring about engorgement of the lungs and increased filling of the right side of the heart. This is said to occur in healthy people at 10,000 feet. It becomes very dangerous in people with impairment of the vascular system, either arterio-sclerosis or chronic heart disease. The symptoms of heart failure, moreover, may not be present until after the patient has returned to the lower level, when he quickly may develop the symptoms of acute cardiac dilatation with fullness in the head and vertigo. The symptoms are especially apt to supervene if the ascent has been rapid, as occurs in railway journeys. The first point in the treatment is to send the patient down to the lower level and let him have absolute rest for several days. The methods of relieving the heart employed by the medical men who have these cases to treat are venesection, followed by the application of counter-irritation with aperients and diaphoretics. As stimulants caffeine and camphor are recommended but not digitalis. Insomnia, which is liable to be troublesome, is treated by wet packs and bromides. Morphine in doses of from one-fourth to one-third of a grain is also used. If the patient recovers he is to be kept perfectly quiet for several weeks or even months.

I will now take up the last group of cases of acute heart failure—namely, that resulting from a diminution in the diastolic blood quantum. The efficient contraction of the cardiac muscle depending upon the proper distension of its cavities during diastole and also upon the normal circulation of blood through the coronary vessels, any condition which interferes with the diastolic filling of the heart by reducing the blood quantum will bring about a rapid acute failure of the organ. This may be brought about in one of three ways:

(1) by a diminution in the total amount of blood; (2) by vaso-motor paralysis which increases the total capacity of the vascular system; or (3) by an increase of pressure in the chest which mechanically prevents the diastolic filling of the heart. The first condition is typically illustrated by hæmorrhage. The indications for the treatment of this accident are (a) to stop the hæmorrhage, and (b) to replace the blood which has been lost by salt solution. The saline must be given intravenously but not unless the hæmorrhage can be certainly stopped. The preliminary syncope is to be treated by raising the foot of the bed so as to increase the diastolic filling of the heart. The legs may then be tightly bandaged or abdominal pressure applied so as to force blood along towards the heart. The patient must be placed in a cool room and physical, emotional, and mental rest completely secured. If the bleeding has been absolutely stopped an intravenous injection of saline solution is then to be given and some diffusible stimulant. If the bleeding has not been certainly stopped, styptics are to be given if there is any probability of their reaching the bleeding spot. Saline is not to be intravenously injected, but after time for clotting has been allowed to pass repeated small subcutaneous injections of saline solution, or saline solution by the rectum, may be administered. The thirst is best relieved by spoonfuls of cold acidulated water. Later, iron will be found a valuable heart tonic. The second condition—namely, vaso-motor paralysis—is seen in shock. Shock probably includes a wider field than simple vaso-motor paralysis, but the researches of Crile have shown that vaso-motor paralysis is a very important factor and this affords definite indications for treatment. According to Crile's³ definitions collapse is an immediate depression which may lead to death and may be primarily due to one or more of the following factors: (1) to cardiac failure; (2) to respiratory failure, resulting from disease or injury of thorax or of the central or peripheral nervous mechanisms; (3) to hæmorrhage; or (4) to vaso-motor paralysis, as in peritonitis, chloroform poisoning, and so on.

Shock is a later depression which may lead to death and is due to impairment or breakdown of the vaso-motor mechanism. It may be added to by any of the factors causing collapse. The vessels have lost their power to accommodate for changes of position, they are toneless, and stimulation of a sensory nerve causes no vasomotor response, or a further fall of blood pressure may result. The blood is largely transferred to the venous side and collects chiefly in the splanchnic vessels.

In the treatment of this condition it must be remembered that prevention is better than cure, and a great deal can be done, as you are all quite well aware, especially in conducting operations, to avoid subsequent shock. The indications for the actual treatment of a case are (1) to restore the vascular tone or (2) to increase the volume of the blood. Strychnine might appear to be an ideal drug for the treatment of this condition, as it is a powerful vaso-motor stimulant; however, Crile has shown that it is practically useless, because the vaso-motor centre is not in a condition to respond and, moreover, strychnine will not produce a rise of blood pressure until the stage of twitching has been reached. It is also known that shock due to over-stimulation of the vaso-motor centre can be produced by strychnine. Better results may be expected to follow the administration of suprarenal extract, which acts on the peripheral vaso-motor mechanism. A single injection of adrenalin is useless, because the subsequent fall of blood pressure is too rapid. If very small amounts are administered at frequent intervals in conjunction with repeated saline infusion the best results are obtained. The saline infusion should not be administered in a single large dose, especially in post-operative shock, but in repeated small doses. The position of the patient is of great importance. The head should be placed low and the feet raised in order to aid the diastolic filling of the heart. The question of diminishing the capacity of the vascular system by external pressure is to be considered. Crile, as you know, has invented a pneumatic suit, by means of which he exerts pressure on the surface of the body; he claims good results from its employment. At any rate bandaging the legs and abdomen can be tried quite easily. Cardiac stimulants are of doubtful value, because the heart will usually respond if sufficiently supplied with blood. The external application of heat is, of course, usually necessary.

² Zangger: THE LANCET, June 22nd, 1903, p. 1730.

³ Crile: Loc. cit.

The last group of cases of acute heart failure with which I shall deal includes those in which there is an increase of pressure in the chest. The heart, as you are aware, has very little suction power and is filled with blood mainly because the pressure in the veins is higher than the pressure in the pericardial sac, in which the pressure is continually negative, this negative pressure being markedly increased during inspiration. An increase of pressure in the pericardium is therefore accompanied by deficient filling of the heart and hence the great danger of acute heart failure. Two conditions with which we have to deal are pericardial effusion and pericardial hæmorrhage. The pericardium readily stretches as the result of pericarditis and will hold a considerable quantity of fluid without its tension being raised to the dangerous limit; the fluid is, moreover, poured out comparatively slowly and hence time is allowed for the stretching of the pericardium. However, if a high pressure occurs the patient will certainly die from acute heart failure unless tapping is resorted to, the needle being introduced into the fourth or fifth left intercostal space near the left edge of the sternum. Pericardial hæmorrhage is much more dangerous because the blood is poured out at a high pressure and rapidly distends the pericardium, which has not time to stretch. The patient dies not from the loss of blood but from the rapid rise of intrapericardial pressure. Tapping is, of course, useless and the patient always dies unless operation is resorted to within about 14 hours. The results of operation are certainly encouraging, as 41 per cent. recover,* cases of injury to the heart, of course, being more favourable than rupture of that organ due to disease.

Practically speaking, rupture of the heart due to fatty degeneration, acute abscess, and so on, always leads to death. The same may be said of a ruptured aneurysm. If the wall of the ventricle or a coronary artery be ruptured as a result of injury the pericardium must be at once opened and the artery tied or the wall of the ventricle sutured. It is advisable to introduce interrupted sutures not involving the endocardium and placed close together. They should be tied during diastole.

Finally, pleural effusion is liable to be accompanied by acute heart failure, and in the days when Trousseau* advocated tapping sudden death was of frequent occurrence. In addition to causing a rise of intrathoracic pressure, pleural effusion obstructs the circulation through the lung and displaces the heart. Whenever the dulness reaches up to the apex of the lung, whether symptoms of respiratory distress are present or not, the patient is in danger of acute heart failure. He may die suddenly from syncope or a slower heart failure may occur, resulting in intravascular thrombosis or œdema of the sound lung. The only treatment for this condition is tapping and the chief indication for tapping is the amount of the effusion.

CEREBRO-SPINAL FEVER.

BY NATHAN RAW, M.D. DURH., M.R.O.P. LOND.,
F.R.S.E., F.R.C.S. EDIN., D.P.H.,

VISITING PHYSICIAN TO THE MILL-ROAD INFIRMARY, LIVERPOOL.

THE somewhat sudden and alarming epidemics of cerebro-spinal fever in Glasgow, Belfast, and other large centres of the United Kingdom have served to direct special attention to this most extraordinary and obscure disease. Isolated or sporadic cases of typical cerebro-spinal fever are constantly occurring in the practice of any large hospital, and I have during the last ten years observed several cases which cropped up in a most mysterious manner, some of them recovering and others rapidly progressing to a fatal termination. Why it is that these sporadic cases should not become epidemic is difficult to understand, and it is still more difficult to understand how the disease is spread with such rapidity amongst the children of a populous centre. The general impression is that the special germ or micro-organism known as the meningococcus of Weichselbaum is conveyed through the air passages directly to the base of the brain. The resemblance in the symptoms of this disease to many other forms of meningitis

renders it extremely difficult of classification and the definition given by the late Mr. Radcliffe is, in my opinion, the most accurate. He describes cerebro-spinal fever as "an acute, epidemic disease, characterised by profound disturbance of the central nervous system, indicated at the onset chiefly by shivering, intense headache or vertigo, or both, and persistent vomiting; subsequently by delirium, apathy or stupor; an acutely painful condition with spasms—sometimes tetanoid—of certain groups of muscles, especially the posterior muscles of the neck, occasioning retraction of the head; and an increased sensitiveness of the surface of the body. Throughout the disease there is marked depression of the vital powers, not unfrequently collapse; and in its course an eruption of vesicles, petechial, or purpuric spots, or mottling of the skin is apt to occur. If the disease tend to recovery, the symptoms gradually subside without any critical phenomena and convalescence is protracted; if to a fatal termination, death is almost invariably preceded by coma. After death the enveloping membranes of the brain and spinal cord are found in a morbid state, of which the most notable signs are engorgement of the blood vessels, usually excessive, and an effusion of sero-purulent matter into the meshes of the pia mater and beneath the arachnoid. To the clinical manifestations of the disease indicated in this definition may be added the presence of Kernig's sign and of tache cérébrale."

From my own personal experience of a great many forms of inflammatory disease involving the brain and spinal cord I would say that the presence in the exudate of the meningococcus of Weichselbaum removed by lumbar puncture is the only absolute indication that we are dealing with true cerebro-spinal meningitis. If this particular organism is discovered and corresponds to the well-defined tests, then we are dealing with a case of epidemic cerebro-spinal meningitis. In a few instances it is impossible to discover the particular organism, but that alone will not negative the true nature of the disease. The full and excellent report of Dr. Gordon made to the Local Government Board is well worthy of careful study, hence it is not necessary to refer to the special characteristics of the micro-organism. The two cases which I record are of profound interest in demonstrating the difficulty, I might say impossibility, of differentiating between this disease and another form of meningitis with similar symptoms during life.

CASE 1.—The patient, a boy, aged ten years, was admitted into Mill-road Infirmary on Feb. 1st, 1907. His mother stated that he had been quite well until a week previous to admission (Jan. 24th), when he came home from school complaining of pain in the head—across the forehead and at the back of the head. He had also complained of pain in the abdomen and had vomited once on the morning before admission. The child had been very quiet and drowsy but irritable and not caring to be touched at all. On the night of Jan. 31st he had screamed out at intervals and had been restless and delirious. The mother said that the child had stated on Jan. 21st that he had been hurt by a football hitting him in the abdomen. He had complained of pain since then and had a slight cough. The bowels were regular.

On admission the patient was unconscious, delirious, and very irritable. The temperature was 103° F., the pulse was 110, and the respirations were 40. When left alone he was quiet but he breathed noisily. When being examined he struggled and was resistive. He did not understand questions and made no attempt to speak. He was not emaciated but there were several petechial spots about the skin. The patient assumed a lateral decubitus. Both knee-jerks were present and were somewhat exaggerated. Kernig's sign was not marked. There was no retraction of the head but there was some stiffness on passive movement. The pupils were dilated equally and there was no squint or nystagmus. There was a discharge from the ear on the right side. The abdomen was not distended, was soft, and moved with respiration. The tongue was dirty and dry and the bowels were constipated. The cardiac rhythm was rapid and regular in time and force. Râles and rhonchi were audible all over the upper and lower lobes of the left lung. There was no loss of percussion resonance. Over the right lower lobe there was loss of resonance. The breathing was bronchial and there were fine crepitation and bronchophony, which were also audible over the back of the right upper lobe. One and a quarter grains of sulphate of quinine were given every four hours and a drachm of brandy at like intervals. A "pneumonia jacket" was applied and seven and a half

* Hill: THE LANCET, Feb. 16th, 1901, p. 491.

* Trousseau: Lectures on Clinical Medicine, vol. III., p. 221 (New Edinburgh Society).

grains of bromide of potassium were directed to be given if required. On the 2nd there was dried purulent discharge in both pinnae. There was dulness of the percussion note and fine and medium râles were heard down the whole of the right side of the chest. A dose of three grains of calomel was given, an ice-bag was applied to the head, and an enema was directed to be administered if required. The patient had a rigor at 7 P.M. and the temperature rose to 104.4°. The pulse was intermittent and the child was unconscious. He was delirious at times and he often cried out. Lumbar puncture was performed at 4.30 P.M. The fluid was clear, serous, and colourless. Cultures were made and the fluid was centrifugalised. Under the microscope the deposit was found to contain diplococci of *Welchsebaum*. On the 3rd the patient was still drowsy and semi-conscious but was not shouting out so frequently and was not so restless. Lumbar puncture was again performed at 12.45 P.M. and the fluid was still found to be clear and colourless. On the 4th the child did not appear to be so comatose as before, was not so restless, and appeared to be able to hear questions. Kernig's sign was marked. There was no distension of the abdomen. There was still some dried pus on the right pinna. The ear was syringed with boric acid lotion, after which a solution of one ounce of perchloride of mercury and three drachms of rectified spirit of wine was dropped in morning and evening. Three grains of calomel were given. On the 5th the patient was deeply comatose. The temperature was 106.4°, the pulse was 160, and the respirations were 58. The pulse was very thready and soft, there were no knee-jerks, and all the limbs were flaccid. The head was still rigid. There was some divergent strabismus. The chest still had râles and rhonchi but there were clearing from the front and were audible in the axilla and the back. The patient was perspiring freely. A tepid sponging brought the temperature down to 101°. An enema was administered. On the 6th the temperature, which on the previous evening had been 100.2°, rose at 2 A.M. to 105°. The patient was rather irritable and tried to rub his eyes and ears. The abdomen was slightly retracted still but was soft. The pulse was very rapid and feeble. Coffee was given. At 4.30 P.M. the patient was much worse, the pulse being very rapid and more feeble (120 per minute). There were marked subcostal tenderness and flocculation with occasional cough. The respirations were 60 and the temperature was 105.4°. A drachm of glycerine as an enema was administered with good result and tepid sponging was ordered when the temperature rose above 103.6°. On the 7th the patient was still unconscious and the pulse was very feeble and rapid. The temperature was 104.4° at 10 A.M. At 1 P.M. a tepid sponging brought the temperature down to 101° and the patient's condition was much improved. Lumbar puncture was performed. The fluid was still clear and was not running so freely as before. A petechial rash was marked on the legs and the body. There was optic neuritis in both eyes. *Mistura digitalis cum strychnina* (two drachms every four hours) was ordered. At 8 P.M. the patient appeared to be much more comfortable and seemed to understand questions and to take notice of affairs. There were slight sweating and increased diuresis. The colour had improved. On the 8th the improvement was not maintained. The pulse was very rapid and feeble and the temperature kept high. The bowels were still constipated. The glycerine enema was repeated. On the 9th the patient remained in the same condition as on the previous day. There were loud creaking râles and rhonchi audible over the entire chest, back and front. Bronchial breathing was present over the right lower lobe only and nowhere else. A tepid sponging was applied twice during the night with good effect. The pulse was very feeble and rapid (140 per minute) and the respirations were 44 per minute. There was a small septic blister over the sacrum. Dry gauze and iodoform powder were used. There was slight purulent, very offensive, discharge from both ears. A soap-and-water enema was administered and two drachms of glycerine per rectum were ordered to be repeated if required. The ear drops and the syringing were continued. On the 11th the patient became comatose and died.

A post-mortem examination was made 12 hours after death. No gross macroscopic lesions were seen on the brain or on the spinal cord. The lungs were in a state of broncho-pneumonia. There were several old calcareous ulceration of the intestine. The kidneys, the spleen, the heart, and the liver were healthy. Post mortem appearances were, in fact, almost negative.

CASE 2.—The patient, a child, aged eight years, was admitted to Mill-road Infirmary on Feb. 13th, 1907. His mother stated that on Feb. 10th the child had complained of severe pain in the head and had vomited. On the 12th he had become very drowsy and had not been roused since. He had taken but little nourishment. The bowels had been opened on the 11th after an aperient but not since.

On admission the temperature was found to be 100° F., the pulse was 104, and the respirations were 26. The patient was lying on his back in a comatose state, the limbs being all flexed and rigid but they could be straightened by continued pressure. There was no rigidity of the neck nor was there retraction. The pupils were equal. There was no paralysis of the eye muscles. The lungs were clear and the abdomen was flat. There was no discharge from the ears. Two grains of calomel and an ounce of white mixture were given in the morning and half an ounce of diaphoretic mixture was ordered to be given every four hours. On the morning of the 14th there were rigidity and retraction of the neck. The patient ground his teeth, the limbs were all flexed and rigid, the knee-jerks were very sluggish, and *tache cérébrale* was well marked. The child uttered no cry. The tongue was furled but moist and there were sordes on the lips. Urine and faeces were passed involuntarily and the patient took no notice of anything. He was not irritable when touched. There were no petechial spots. At 3.15 P.M. lumbar puncture was performed when about 30 cubic centimetres of slightly opalescent fluid ran out. At 11 P.M. the patient was perspiring. The neck was very rigid but not very retracted. The patient was not so listless. There were variable squints (slight). Ten cubic centimetres of cerebro spinal fluid were centrifugalised. It was slightly opalescent. There was a fair amount of whitish yellow deposit but no red deposit. Microscopical examination showed a large excess of leucocytes, multinuclear and lymphocytes, a very few red blood corpuscles, and no organisms. On the 15th the patient still perspired profusely. Millaria appeared all over the upper chest. The neck was rigid and the child could not put his chin on his chest. The arms were folded across the chest and were rather rigid. The legs were straight now but Kernig's sign was present. The knee-jerks were slight and there was slight Babinski's sign. There was incontinence of urine and faeces and the patient would not respond to speech. The pupils were dilated but they reacted to light. There was paresis of the external rectus of the left eye. The patient was taking nourishment fairly well. The bowels were rather relaxed; the abdomen was flat. There was no vomiting. There had been no shouting out since admission. Sulphate of quinine mixture, one drachm, was given every four hours. The patient spoke a little when spoken to. He said "What" and "Well." On the 16th he would not speak. The tongue was moist but furled. Kernig's sign was present. There were no spots but some subcuticular mottling was observable on the thighs. The squint was still present. There were some large moist râles to be heard at the left base and some rhonchi at the front chest. At 5.30 P.M. lumbar puncture was performed and about 20 cubic centimetres of fluid ran out, at first in a stream, not drops. Ten cubic centimetres of the fluid were centrifugalised. Numerous lymphocytes and multinuclears were in the field but no organisms were present. At 9 P.M. the patient recognised his father and talked in a delirious way. On the morning of the 17th he again talked a little but was delirious. The head was still very rigid and the arms were folded on the chest. The legs were straight but Kernig's sign was present. The patient did not shout out at all, but he was restless. He had not passed urine for 12 hours. The tongue was moist but was covered with dirty white fur. A quarter of a grain of calomel was given every two hours. On the 18th two drachms of brandy were ordered to be given every three hours. There was slight ptosis on the right side and the right pupil was larger than the left one. There was no vomiting. The patient had uttered no cry since admission. He had tremor of the limbs (upper) again on this day. There was a profuse crop of millaria on the chest. At 8 P.M. lumbar puncture was performed when about 15 cubic centimetres of fluid were withdrawn; at first it ran out, not in drops; it was slightly turbid. Microscopical examination showed an excess of cells as before, but no organisms. On the 19th the patient was rather worse. He was restless and he uttered sighing noises. The head was not retracted, but the neck was rigid. The back also was rigid. At 10 P.M. as the patient

The last group of cases of acute heart failure with which I shall deal includes those in which there is an increase of pressure in the chest. The heart, as you are aware, has very little suction power and is filled with blood mainly because the pressure in the veins is higher than the pressure in the pericardial sac, in which the pressure is continually negative, this negative pressure being markedly increased during inspiration. An increase of pressure in the pericardium is therefore accompanied by deficient filling of the heart and hence the great danger of acute heart failure. Two conditions with which we have to deal are pericardial effusion and pericardial hæmorrhage. The pericardium readily stretches as the result of pericarditis and will hold a considerable quantity of fluid without its tension being raised to the dangerous limit; the fluid is, moreover, poured out comparatively slowly and hence time is allowed for the stretching of the pericardium. However, if a high pressure occurs the patient will certainly die from acute heart failure unless tapping is resorted to, the needle being introduced into the fourth or fifth left intercostal space near the left edge of the sternum. Pericardial hæmorrhage is much more dangerous because the blood is poured out at a high pressure and rapidly distends the pericardium, which has not time to stretch. The patient dies not from the loss of blood but from the rapid rise of intrapericardial pressure. Tapping is, of course, useless and the patient always dies unless operation is resorted to within about 14 hours. The results of operation are certainly encouraging, as 41 per cent. recover.⁷ cases of injury to the heart, of course, being more favourable than rupture of that organ due to disease.

Practically speaking, rupture of the heart due to fatty degeneration, acute abscess, and so on, always leads to death. The same may be said of a ruptured aneurysm. If the wall of the ventricle or a coronary artery be ruptured as a result of injury the pericardium must be at once opened and the artery tied or the wall of the ventricle sutured. It is advisable to introduce interrupted sutures not involving the endocardium and placed close together. They should be tied during diastole.

Finally, pleural effusion is liable to be accompanied by acute heart failure, and in the days when Trouessau⁸ advocated tapping sudden death was of frequent occurrence. In addition to causing a rise of intrathoracic pressure, pleural effusion obstructs the circulation through the lung and displaces the heart. Whenever the dulness reaches up to the apex of the lung, whether symptoms of respiratory distress are present or not, the patient is in danger of acute heart failure. He may die suddenly from syncope or a slower heart failure may occur, resulting in intravascular thrombosis or œdema of the sound lung. The only treatment for this condition is tapping and the chief indication for tapping is the amount of the effusion.

CEREBRO-SPINAL FEVER.

BY NATHAN RAW, M.D. DURH., M.R.O.P. LOND.,
F.R.S.E., F.R.O.S. EDIN., D.P.H.,

VISITING PHYSICIAN TO THE MILL-ROAD INFIRMARY, LIVERPOOL.

THE somewhat sudden and alarming epidemics of cerebro-spinal fever in Glasgow, Belfast, and other large centres of the United Kingdom have served to direct special attention to this most extraordinary and obscure disease. Isolated or sporadic cases of typical cerebro-spinal fever are constantly occurring in the practice of any large hospital, and I have during the last ten years observed several cases which cropped up in a most mysterious manner, some of them recovering and others rapidly progressing to a fatal termination. Why it is that these sporadic cases should not become epidemic is difficult to understand, and it is still more difficult to understand how the disease is spread with such rapidity amongst the children of a populous centre. The general impression is that the special germ or micro-organism known as the meningococcus of Weichselbaum is conveyed through the air passages directly to the base of the brain. The resemblance in the symptoms of this disease to many other forms of meningitis

renders it extremely difficult of classification and the definition given by the late Mr. Radcliffe is, in my opinion, the most accurate. He describes cerebro-spinal fever as "an acute, epidemic disease, characterised by profound disturbance of the central nervous system, indicated at the onset chiefly by shivering, intense headache or vertigo, or both, and persistent vomiting; subsequently by delirium, often violent, alternating with somnolence or a state of apathy or stupor; an acutely painful condition with spasm—sometimes tetanoid—of certain groups of muscles, especially the posterior muscles of the neck, occasioning retraction of the head; and an increased sensitiveness of the surface of the body. Throughout the disease there is marked depression of the vital powers, not unfrequently collapse; and in its course an eruption of vesicles, petechial, or purpuric spots, or mottling of the skin is apt to occur. If the disease tend to recovery, the symptoms gradually subside without any critical phenomena and convalescence is protracted; if to a fatal termination, death is almost invariably preceded by coma. After death the enveloping membranes of the brain and spinal cord are found in a morbid state, of which the most notable signs are engorgement of the blood vessels, usually excessive, and an effusion of sero-purulent matter into the meshes of the pia mater and beneath the arachnoid. To the clinical manifestations of the disease indicated in this definition may be added the presence of Kernig's sign and of tache cérébrale."

From my own personal experience of a great many forms of inflammatory disease involving the brain and spinal cord I would say that the presence in the exudate of the meningococcus of Weichselbaum removed by lumbar puncture is the only absolute indication that we are dealing with true cerebro-spinal meningitis. If this particular organism is discovered and corresponds to the well-defined tests, then we are dealing with a case of epidemic cerebro-spinal meningitis. In a few instances it is impossible to discover the particular organism, but that alone will not negative the true nature of the disease. The full and excellent report of Dr. Gordon made to the Local Government Board is well worthy of careful study, hence it is not necessary to refer to the special characteristics of the micro-organism. The two cases which I record are of profound interest in demonstrating the difficulty, I might say impossibility, of differentiating between this disease and another form of meningitis with similar symptoms during life.

CASE 1.—The patient, a boy, aged ten years, was admitted into Mill-road Infirmary on Feb. 1st, 1907. His mother stated that he had been quite well until a week previous to admission (Jan. 24th), when he came home from school complaining of pain in the head—across the forehead and at the back of the head. He had also complained of pain in the abdomen and had vomited once on the morning before admission. The child had been very quiet and drowsy but irritable and not caring to be touched at all. On the night of Jan. 31st he had screamed out at intervals and had been restless and delirious. The mother said that the child had stated on Jan. 21st that he had been hurt by a football hitting him in the abdomen. He had complained of pain since then and had a slight cough. The bowels were regular.

On admission the patient was unconscious, delirious, and very irritable. The temperature was 103° F., the pulse was 110, and the respirations were 40. When left alone he was quiet but he breathed noisily. When being examined he struggled and was resistive. He did not understand questions and made no attempt to speak. He was not emaciated but there were several petechial spots about the skin. The patient assumed a lateral decubitus. Both knee-jerks were present and were somewhat exaggerated. Kernig's sign was not marked. There was no retraction of the head but there was some stiffness on passive movement. The pupils were dilated equally and there was no squint or nystagmus. There was a discharge from the ear on the right side. The abdomen was not distended, was soft, and moved with respiration. The tongue was dirty and dry and the bowels were constipated. The cardiac rhythm was rapid and regular in time and force. Râles and rhonchi were audible all over the upper and lower lobes of the left lung. There was no loss of percussion resonance. Over the right lower lobe there was loss of resonance. The breathing was bronchial and there were fine crepitation and bronchophony, which were also audible over the back of the right upper lobe. One and a quarter grains of sulphate of quinine were given every four hours and a drachm of brandy at like intervals. A "pneumonia jacket"

⁸ Trouessau: Lectures on Clinical Medicine, vol. III, p. 221 (New Sydenham Society).

nature of the infection. It is highly improbable, judging from the analogy of other cases of wound infection, that the true incubation period is over 24 hours in length. If, therefore, the initial rigor, or the first rise of temperature, occurs at a longer period than this after confinement, the assumption is that the patient was not infected at that time, but subsequently during the puerperium. In the "practitioners'" cases the average day of onset was the third and in the "midwives'" series between the fourth and fifth. It would then appear that the midwife has not usually infected the patient by her actions at the time of the confinement. In subsequent infection the main factor, I believe, is the administration of vaginal douches which were given in almost every instance in this series. Possibly the neglect adequately to protect the external genitalia after confinement must also be considered.

Apart from these cases only, I may say that my experience leads me to believe that the routine use of the vaginal douche is the predominating factor in a large number of cases of puerperal fever. The injections are given with a Higginson's syringe almost invariably, and even if this is not used for enemata also—and I may add here that by no method of supervision whatever is it possible to insure that it shall not be so employed—infection of the interior of the instrument takes place whenever a vaginal douche is given, and the syringe can only be disinfected by prolonged boiling, which very few of the inexpensive instruments on the market will stand without becoming useless.

I may here express my own opinion that the carrying of a Higginson's syringe by midwives should be made illegal by supervising authorities. It is quite easy to give an enema by means of the douche can, and even if the same nozzle were to be used for rectal and vaginal injections by a careless or unscrupulous midwife, only the exterior and not the interior also of the instrument would be thereby infected.

The bacteriology.—In every instance swabs were taken with due precautions from the interior of the uterus and cultures were made therefrom in the hospital laboratory. The results are as follows. Streptococci were present in 29 cases. Of these, bacillus coli communis was present also in five cases; bacillus coli communis was present alone in one case; gonococci were present alone in two cases; staphylococci were present alone in one case; and a bacillus, as yet not identified, was present alone in one case. In 15 instances there was either no growth on the tubes or some suspicion of contamination of the swab. In 27 cases samples of blood taken from the basilic vein were examined also. Out of these no growth was obtained in 19 cases, whilst streptococci were present in eight. No other organisms were found in any of the blood specimens, though a full examination was made in each case.

For the identification of the various organisms the usual bacteriological methods were employed. I do not propose to enlarge on the bacteriology of puerperal septicæmia at present, but I should mention that the proportion of cases in which streptococci were found is greater in the 1906 cases than in those of the previous year. This is, I believe, to be explained by the fact that in 1905 there was a much larger proportion of "midwives'" as distinct from "practitioners'" cases. In the former late infection is the rule, and bacillus coli is present more frequently.

The nature of the lesion.—As I have stated, there was, in almost every case, evidence of intense toxæmia on admission, but the source of this was not always easy to determine. It is, however, possible to classify the cases somewhat roughly according to the nature of the lesion and we have accordingly the following. 1. *Cases of retained placenta or membranes.*—Of these there were 18, but it is important to note that in all except four the condition had passed from that of sapræmia only to septicæmia when the patient was first seen. In these the recovery was slow and often interrupted by pelvic inflammation or abscess, whereas in the purely sapræmic cases a marked and sustained improvement followed the removal of the retained products. This series also shows the futility of treating puerperal fever by intra-uterine douching only, without examination of the interior of the uterus, for in almost every instance the interior of that cavity had been douched by a medical man previously. There was one death only in this series. 2. *Injuries.*—These were apparently the cause of the toxæmia in seven cases and in all the lacerations had been produced by the use of instruments. In one case there was a tear extending through the vaginal vault and the side of the cervix

through the broad ligament into the peritoneal cavity which had been caused by the use of Hegar's dilators without preliminary anaesthesia or steadying of the cervix. In another, an almost precisely similar lesion followed manual extraction of the placenta. In the remaining five cases the premature application of forceps was responsible for the injury. Fortunately all these recovered, though general peritonitis supervened in one instance. 3. *General peritonitis.*—Eight cases, with four deaths. In all of this series the abdominal cavity contained free pus to an amount of at least one pint. All were treated by laparotomy and drainage with flushing in one case. When it is noted that the supervention of general peritonitis in puerperal cases is almost always regarded as an indication that death is imminent and unavoidable it is evident that this series, as far as it goes, is an indication that it is not always wise to refuse operation in moribund cases. 4. *Pelvic suppuration.*—Three cases, all fatal. Here there was a collection of pus in some portion or other of the pelvis shut off by adhesions from the general peritoneal cavity. These were all apparently hopeless cases in which an accurate diagnosis was impossible and an exploratory operation was therefore performed on admission. This series does not include cases in which pelvic suppuration occurred in the course of convalescence and in which the results were much better. 5. *General septicæmia without obvious lesion.*—13 cases with four deaths. In each of these there was marked subinvolution of the uterus, but no evidence of retained placenta or of laceration. Probably most, if not all, were instances of septic endometritis.

The treatment adopted.—In all but eight cases the procedure adopted on admission was as follows. After thorough preparation of the parts the patient was examined in the operating theatre in the lithotomy position. At first a general anaesthetic was given, but latterly, on the suggestion of Sir William Sinclair, I have with advantage given alcohol internally followed by the hypodermic injection of morphine instead. The parts were then exposed by an Auvar's weighted speculum and the cervix steadied with volsellæ. Cultures were taken from the interior of the uterus, which was then curetted with a specially made instrument. This is shaped in general like a Sim's sharp curette and is made as light as possible. The cutting hoop, however, is pear-shaped and broadest at its extremity, where it measures an inch and a half across. After as thorough a removal of the endometrium as possible, the raw surface was swabbed thoroughly with undiluted izal fluid and the cavity was then packed with izal gauze, the vagina being loosely plugged also. Sometimes an intra-uterine douche of 1 in 500 izal solution was used also, but as a rule no douching was thought necessary at the time of the operation or subsequently. In two instances the curetting and swabbing were repeated on the next day. When curetting was not done laparotomy was performed for the reason stated in the table under each case. It will therefore be seen that the "routine" treatment of these cases consisted in vigorous disinfection of the uterus—a procedure which has frequently been described as almost necessarily fatal to the patient.

The objection usually urged against the use of the curette in septic conditions is that the barrier of leucocytes on the maintenance of which the patient's only hope of safety is supposed to lie is thereby disturbed, with the result that the organisms which it formerly restrained are free to make their way into the blood stream. It is, however, to my mind more probable that it is just in these cases of septic disease that the barrier is either useless or, more probably, non-existent and that what is wanted is something that will either take away or kill the organisms themselves. Moreover, though I have now examined sections from a somewhat large number of puerperal uteri in cases of septicæmia, I have only twice seen any signs of this barrier, even in cases where curetting had not been performed.

In this series the uterus has been removed as a last resource three times, once vaginally and once abdominally by myself, and once vaginally by Sir William Sinclair, who saw the case in consultation. In no case did recovery ensue. I have no experience of removing the uterus before the patient becomes intensely ill, as I should in any case try thorough local disinfection first. There can be no doubt that the shock following the removal by any method of the puerperal uterus is very great. There have been no cases in which thrombosed veins in the broad ligaments have been detected and ligatured; in fact, there have been no cases of thrombosis in any situation in this series at all. In three

had not passed urine since 1 A.M., a soft rubber catheter was passed. The urine was acid and clear and its specific gravity was 1010. At midnight on the 20th a catheter was passed. On the 21st the patient was in a dying state. There were no fresh focal symptoms.

A post-mortem examination was made 16 hours after death. Pus was found in the interpeduncular space and over the upper surface of the cerebellum in the middle line. The vertex of the brain was normal. Miliary tubercles (early) were discovered in both lungs and in the spleen and liver. There was a caseating patch in the spleen of about the size of the head of a bonnet-pin, as well as some caseating material about the glands round the head of the pancreas. The mesenteric glands were normal. The bronchial glands were not noticeable. On Feb. 25th some smears from the caseating patch in the spleen and the caseous glands about the head of the pancreas showed numerous tubercle bacilli.

The above two cases show the impossibility of making an accurate diagnosis between cerebro-spinal and acute tuberculous meningitis, especially in time of epidemic when attention is turned in that direction. The absence of tubercle bacilli from the lumbar puncture exudate is, of course, no reason for negating tubercle, as they are only recovered in a small percentage from such exudations. The rapid onset of the tuberculous case is unusual, whilst in both cases there were skin rashes of a petechial character. I felt quite certain that I had to deal with a case of genuine cerebro-spinal meningitis and it was only at the post-mortem examination that that opinion was reversed. Had there not been the presence of an epidemic we would probably have looked upon the case as one of acute tuberculous meningitis. The withdrawal of quantities of cerebro-spinal fluid by lumbar puncture was followed in every instance by marked amelioration of the symptoms and even rapid improvement for a time, due evidently to the relief of pressure, but so soon as the fluid re-accumulated the symptoms seemed to arise with even greater severity than before. As a therapeutic measure, however, I would strongly urge repeated lumbar puncture and injections of lysol or some of the silver salts, or even permanent drainage of the spinal canal. No other treatment with which I am acquainted seemed to have the slightest curative effect on the disease, although the symptoms, of course, were immensely relieved. I have had no experience of the special meningococcus serum, but it is well worthy of trial. In fact, everything possible ought to be tried in such a malignant and fatal disease.

For the careful and accurate observations on these cases I am indebted to my colleagues, Dr. Arthur Hendry and Dr. R. G. Willis, resident medical officers in the hospital.
Liverpool.

A SERIES OF CASES OF PUERPERAL SEPTICÆMIA;

WITH COMMENTS.

By A. KNYVETT GORDON, M.B. CANTAB.,

MEDICAL SUPERINTENDENT OF MONSALL HOSPITAL; LECTURER ON INFECTIOUS DISEASES IN THE UNIVERSITY OF MANCHESTER.

DURING the year 1906 there have been discharged from Monsall Hospital 49 completed cases of puerperal fever and it has occurred to me that some particulars of their condition may be interesting to others besides myself if only for the reason that clinical observations of this class of disease have not hitherto been reported with any degree of frequency in this country. Moreover, as the cases have all been treated by the same medical and nursing staff it is perhaps rather more possible than usual to compare them with each other.

I would call attention, in the first place, to the annexed table, in which the details of each case are briefly set forth. It is not pretended that this is in any sense complete, but it is, I think, useful inasmuch as it shows the type of case that is admitted to the isolation hospital of a large city. These details I propose to analyse and to comment upon briefly.

The results.—There is a gross mortality of 12 cases, or 24 per cent. Of these, four were obviously moribund on admission, and, in fact, died within a few hours of their arrival. It is, I think, greatly to be regretted that isolation hospitals are treated so badly in this respect by the general

practitioner. When it must be obvious that the patient has but a few hours to live it can serve no good purpose, as far as his illness is concerned, to have him removed to hospital—usually it accelerates his end. It is often convenient, no doubt, that a death shall not occur in the particular house, or in the practice of the certifying medical man, but, on the other hand, the procedure adopted at the hospital, be it medical or surgical, is often debited with the patient's death, and the progress of science and the good that the hospital can do in other cases are thereby considerably hindered. In this series if the moribund cases could be deducted the death-rate would be reduced to 16 per cent. Of the remaining eight, one died from an attack of pneumonia which began six weeks after admission, when the patient was apparently convalescent, and had no apparent connexion with the original illness.

Another point is that in only two instances was the patient not obviously in danger of her life when admitted. This series does not, therefore, include those mild cases of septic intoxication, which yield to gentle local treatment, or, it may be, to purgatives alone, which may occur in private practice or in the clinique of the maternity hospitals. If these are included, the statistical fatality of any series may be very low indeed. Such cases have, as a matter of fact, never been sent to Monsall Hospital at all.

That the cases have, as a rule, not been admitted until the treatment adopted has been obviously useless, is shown by the fact that the average interval elapsing between the calling in of the medical man by the midwife, or (in the cases where he has been in attendance all along) from the onset of the signs of sepsis to the notification of the case was a period of four and a half days. In other words, what must be admitted to be the most important period in the disease from the therapeutical point of view has been spent in the application of ineffective—often futile—measures. As a matter of fact, this series, as far as it goes, is not a bad record of the uselessness of such measures as vaginal and intra-uterine douches with a little quinine internally in cases of severe septic infection.

With regard to those discharged as cured it is necessary to observe that the patients have not been sent home until they have had sufficient rest in hospital to enable them to perform ordinary house work without pelvic pain or inconvenience, and have resumed their normal weight. In the great majority the uterine had recovered its mobility. As will be seen from the record their stay in hospital has on this account been frequently prolonged, the average detention of all cases being 40 days, and of those that recovered 60 days. The only exception to this is case No. 29, where the patient was discharged to the workhouse infirmary in a somewhat weak state owing to the pressure on our accommodation that existed at the time. As far as possible lacerations of the vagina and perineum and adhesions in the pelvis have been treated before the patient left hospital.

The cause of the illness.—In every case a detailed account of the circumstances that preceded the removal of the patient has been furnished me by the courtesy of the medical officer of health (Dr. J. Niven) and the medical officer to the midwives supervising committee (Dr. M. Merry Smith), to whom I am much indebted. It is possible, therefore, to divide the cases into those attended at the confinement by a medical man and those where a midwife only was present. There were some cases also where the woman was confined in solitude or attended by a neighbour only. The "practitioners'" cases are 28 in number, the "midwives'" are 16. It does not, however, follow that the medical man was responsible for the infection of the patient in all cases where he was present at the confinement, for in many a midwife or trained nurse was there also and may well have made internal examinations, and it is, moreover, probable in some instances that infection took place during the puerperium from contact with dirty clothes or the unskilful administration of vaginal injections. Evidence of the responsibility of the medical attendant is seen more clearly when an inquiry is made into the degree of interference that took place at the confinement. In 11 of these 28 cases there is a history of the use of forceps combined with a variety of laceration of the parts (seen on admission) that could not have resulted from natural causes only. There were other instances also in which the hand had been introduced into the uterus for the removal of the placenta in which infection by this means is at least probable, but it is not possible to put this statistically.

The length of the incubation period gives some clue to the

instances pelvic abscesses occurring in convalescence were opened extra-peritoneally through the vagina; all recovered. In another case the general peritoneal cavity was opened through the vagina; diffuse suppuration in the parametrium, together with a large tubo-ovarian abscess, was found. This case did not recover.

Serum treatment.—Antistreptococcal serum was given on admission to 20 patients, the dose ranging from 50 cubic centimetres in three cases to 200 cubic centimetres in three; the usual amount injected was 100 cubic centimetres. In these 20 cases streptococci were found in the uterus in 16 instances and in the blood also in five. The sera employed had been prepared in the Wellcome Research Laboratory at first from five cultures of streptococci obtained from material removed from the uterus and blood of cases treated at Monsall Hospital. Latterly more strains from other puerperal sources had been, I understand, added. So far I have been unable to discover any difference in the action of these two brands.

The whole subject of the use of bacteriocidal sera in puerperal fever is beset with difficulties, which have not been diminished by the publication of cases in which active local treatment has been adopted together with the administration of small quantities of a (possibly stale) serum and the result attributed to the serum only. My own practice is to give a polyvalent serum in all cases in which examination fails to discover any gross lesion and to any in which streptococci are subsequently found in the blood. I have never seen any ill effects from the sera except the production of transient rashes and, in some instances, of joint pains also. I feel, however, that the administration of a single dose of 10 or 20 cubic centimetres is almost useless and that it is better to give any quantity in one injection than in repeated small doses. The prevailing factor is one of time. The sooner it is given, the better.

It is not, of course, possible to come to any definite conclusions statistically from such a small series as 49 cases of puerperal sepsis. For most of the incidental remarks I have made I have drawn upon my previous experience also. As far as they go, however, the 1906 cases have strengthened my belief that in such a terrible disease as puerperal fever we must act as we should in any other variety of wound

fever and try active local disinfection promptly, and that collections of pus, whether they be inside or outside the peritoneal cavity, must be treated by incision and drainage. As adjuncts to these surgical methods that have received due recognition in every other region of the body, such measures as the use of bacteriocidal sera and some drugs are occasionally useful, but they can never cure by themselves. As long as puerperal fever continues to be treated by vaginal douches and bottles of medicine only it will, I believe, always have a high mortality. It is, of course, better still to prevent its occurrence altogether.

Manchester.

CHLORETONE AND ITS USES, ESPECIALLY IN CHOREA.¹

BY W. ESSEX WYNTER, M.D. LOND., F.R.O.P. LOND., F.R.C.S. ENG.,

PHYSICIAN TO, AND LECTURER ON MEDICINE AT, THE MIDDLESEX HOSPITAL.

It has been said by an eminent French physician that what impresses the patient's friends is a correct prognosis, what impresses other medical men is an accurate diagnosis, but what impresses the physician himself is the occurrence of any decided benefit from the employment of a particular remedy. It is because we are naturally rather impressed with what is new than with what is already familiar that this statement may be regarded as applying to new remedies or new applications of old ones, and it is of such an impression, while still fresh, that I propose to speak to-day.

Chloretone, which is trichloro-tertiary-butyl-alcohol, is obtained by the interaction of chloroform, acetone, and an alkali. It is a white crystalline compound having a camphor-like odour and taste, and may be melted and sublimed at the body temperature. It is only slightly soluble in water but easily so in glycerine, alcohol, petroleum, or oil. The dose is from five to 25 grains in cachet or solution in one of the

years, but no other illness. There was no history of acute rheumatism or of syphilis in the family, the other members of which were quite healthy. The patient was very cyanosed and clubbing of the fingers, the toes, and the nose was well marked. A systolic murmur was heard over the præcordium, probably due to defect of the interventricular septum; it was best heard to the left of the sternum and in the third and fourth intercostal spaces, but was also audible at the apex beat of the heart and in the second intercostal space; it was not conducted towards the left clavicle. There were no signs of any of those diseases of the lungs which have hitherto been found associated with clubbing of the fingers and osteoarthropathy; the tuberculo-opsonic indices observed on five separate occasions by Mr. D. Embleton were 0.98, 0.78, 0.96, 0.96, and 0.82. The blood examination showed 8,320,000 red corpuscles and 9300 white corpuscles per cubic millimetre; the percentage of hæmoglobin was 150 and the colour index was 0.94; the polymorphonuclear cells numbered 60.2 per cent., the small lymphocytes 19.9 per cent., the large lymphocytes 12 per cent., the hyaline cells 6.9 per cent., and the eosinophile cells 1 per cent. Besides the clubbing above referred to there was obvious swelling of both legs due to thickening of the lower ends of the tibiae and fibulae, and there was slight swelling of the bones of the forearms, of the wrists, and of the shafts of the metacarpal and phalangeal bones.

Radioscopic examination.—Compared with the corresponding bones of the patient's sister, who was quite healthy and of almost the same height and build, there was very considerable enlargement of the tibiae and fibulae of both legs, especially of the lower two-thirds, more marked in the right limb; irregular bony deposits were present at the attachment of the interosseous ligaments to the adjacent tibiae and fibulae. The upper halves of the shafts of the femora showed increase of the mass of bone, but in a more marked degree, especially in the right leg; the head, the neck, and the lower halves of the femora appeared to be normal. The first and second phalanges of the fingers and thumbs, the metacarpal bones, the first and second phalanges of the toes, the metatarsal bones, and the bones of both forearms showed very slight thickening; there was no bony increase of the terminal phalanges of the fingers or toes.

This case is of special interest in several directions. In the first place it confirms the belief that Pierre Marie's sign-complex is not a feature of particular forms of lung disease only; such as bronchiectasis, tuberculosis, empyema, neoplasm; &c., for the patient was quite free from any signs or symptoms of pulmonary disease. The changes in the bones and the joint pains constitute "osteo-arthropathy" which, combined with clubbing, is known under the title given by Pierre Marie² as pulmonary hypertrophic osteo-arthropathy; the latter observer and Bamberger³ considered that the genesis of this sign-complex depended on the effects of toxins formed in the lungs; we consider that everything points to the absence of any toxic focus in the lungs of this case; tuberculosis of the lungs, the most common infection in congenital heart disease, may yield no physical signs and yet be present; that this is not so in this case is shown by the existence of normal opsonic indices above quoted—a condition of affairs which could not occur if a tuberculo-toxin were circulating in the system so widely as to produce the above diffuse osteo-arthropathy. A mechanico-toxic cause of clubbing and of osteo-arthropathy has been advanced recently by Bécclère⁴ and by Groedel⁵ and confirmed by an observation by Berent⁶; clubbing of the fingers has long been known to occur in one hand⁷ in cases in which an aneurysm has caused interference with the circulation of the limb and Groedel and Berent have shown that bone changes may also occur in such cases; the toxic substance or substances must in these cases be generated locally and be derivations of tissue metabolism. Their retention, owing to the obstructed circulation, is considered to be responsible for the clubbing and for the bone and joint changes. We consider that this case gives support to the view of Bécclère and of Groedel because the greatest bone change is noticed in the

lower extremities, gravity tending to increase the stagnation of the blood in these parts; that mechanical obstruction is in the first place responsible for the change is also shown by the fact that the patient has suffered for as long a period as ten years frequently and immediately from pain in the lower limbs on standing or walking.

This case is finally a unique one, for, so far as we are able to ascertain, there are no other reports in the literature of cases of congenital heart disease being associated with Marie's sign-complex in the absence of lung disease; Bamberger's eighth case was one of congenital heart disease but was complicated by the presence of tuberculosis, and Thorburn's⁸ case (footnote to his paper), though occurring in a boy, is not stated to be due to congenital as opposed to acquired heart disease; the latter association has been established by Bamberger. The distribution of the changes, mainly in the lower extremities of our case, is also very unusual and, as already stated, in the absence of any focus of disease in the lung supports the view that clubbing and osteo-arthropathy are due to the effects of tissue toxins normally generated at the periphery but prevented from being rapidly removed owing to the impairment of the circulation, in our case dependent upon congenital heart disease, in others upon the existence of lung disease, of acquired heart disease, and even, it is stated, of impaired action of the diaphragm in cases of hypertrophic cirrhosis of the liver.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

TWIN OVUM IN A TUBAL PREGNANCY.

BY ALLAN F. RUTHERFORD, M.B. EDIN.,
ASSISTANT SURGEON TO THE NORTH LOSSDALE HOSPITAL.

THE rarity of the above condition lends interest to the accompanying illustration from a case recently, under my care.

The patient, aged 39 years, married in January, 1890, had a miscarriage at about three months in May of the same year, had a uterine polypus removed 12 months later, and in February, 1892, was delivered of an eight months' child.

Twin ovum in tubal pregnancy.

In 1896 she had a "false conception" (the description seems to point to hydatid mole), followed by an attack of peritonitis

above-mentioned solvents. The first account of the drug in English medical literature is in THE LANCET of Jan. 13th, 1900, and so far as I am aware it was first employed by Messrs. Parke, Davis, and Co. in 1899 as a preservative for their solutions of adrenalin.

On account of its local anæsthetic effect I was prompted to employ this drug in painful and irritable conditions of the stomach, such as gastritis, cancer, gastrodynia, ulcer, and especially in those cases of pain, vomiting, and hæmatemesis so frequently associated with chlorosis and scarcely yet completely removed from the category of gastric ulcer, with which they are by no means identical. In doses of five grains or more in petroleum emulsion it has a remarkably soothing effect both on pain and vomiting and exercises a deterring influence on fermentation, resembling in this carboic acid. It was while using chloretone for this purpose that its hypnotic effect became apparent, and I have since employed it satisfactorily in ten-grain doses simply to procure sleep, though the state of quietude induced by the smaller doses is itself a very great alleviation of painful and protracted illness, such as the gastric conditions to which I have referred.

The local anæsthetic effects have been found of value in vaginal pruritus as exercised by a 0.4 per cent. solution in warm water, or by five-grain suppositories in hæmorrhoids. The sedative effect on the brain, similar to that of the bromides but more rapidly induced, associated as it is with a similar effect on the stomach, led to its early employment for sea-sickness, and it is in connexion with this distressing malady that its reputation has chiefly been established. Five grains in powder taken a quarter of an hour before embarking will generally insure complete immunity from sickness during the Channel passage even in rough weather, and the drug does not appear to lose its efficacy by repetition, as is the case with some others. A young French lady, who was invariably ill during the crossing to Dieppe, since being fortified with chloretone has only once suffered and that in a way which suggests a useful hint in prescribing. Having performed the outward journey "tute, cito et jucunde" under the influence of one of the five-grain powders of which she was provided with four, the other three were carefully deposited in a purse against her return after the summer holiday. Then accompanied by a friend, to whom she promised immunity from the discomforts of the sea on the strength of this new remedy, she confidently embarked and proceeded to share the remaining doses. One paper after another was opened but all were empty. In the hot weather the chloretone had evaporated and vanished, leaving nothing behind but disappointment and the prospect of a miserable voyage, which was amply verified in both cases. As negative evidence this was distinctive testimony to the value of the drug and has been subsequently remedied by inclosing it in impervious wrappers such as paraffin paper.

When taken at intervals in similar doses longer voyages have been undertaken without discomfort—such, for instance, as that across the Atlantic. The drug was taken about 20 minutes before meals two or threetimes a day during rough weather and the journey was completed without a qualm. A more general knowledge of this remedy will certainly save a large amount of discomfort and in those who suffer continuously will enable journeys to be undertaken which were formerly dangerous or actually impossible.

I have dwelt upon these effects of chloretone as they have led up to its employment in another class of cases for which we have hitherto possessed no efficient remedy. I refer to chorea. During the past 12 months the opportunity has occurred of exhibiting the drug in some 14 cases and the result has been so striking and uniform that though the number is small it is worth making known that those who have wider opportunities may further test its reliability. In these cases, both boys and girls between the ages of seven and 12 years, five grains of chloretone in half an ounce of petroleum emulsion were given three times a day for two and sometimes three days; there was in all of them such a marked diminution of the choreic movements that the dose was then halved and sometimes given only twice and even once a day according to the severity and progress of the case. The number of days in which the drug was continued varied from five to ten, by which time it was omitted and either steel wine with arsenic or cod-liver oil was substituted to meet the anæmia and feebleness which usually accompanied the disease. Under this treatment the duration of choreic movements was limited to nine days and the stay in hospital to three weeks on an average. This is a great advance in the treatment of chorea, which even with the advantage of hospital

régime usually extended to double and treble that time. These advantages consist in rest in bed with isolation and liberal dietary. When convalescing the patients were encouraged to knit or crochet or to use the hands in some such manner so as to practise purposive movements and also as a test of steadiness.

Many patients on admission were unable to feed themselves, experienced considerable difficulty in speech, and in some cases needed padding in their cots to prevent bruising in their uncontrolled movements. It was found that those cases which came under treatment early benefited most. Of the 14 which took chloretone, two were removed from the hospital before they were quite recovered on account of contracting röteln, and two others resisted the treatment for a longer time—one, a girl, aged ten years, who had suffered from chorea for three years with short remissions, and another girl, aged seven years, who, after four months' chorea before admission, appeared rather to be cured by the relief of constipation, which had been a marked feature, this being effected in 21 days.

With any comparatively new drug exerting marked beneficial effects the question always arises as to drawbacks, and in the present instance there are some, though not of serious account. Two of the cases exhibited exfoliation of the skin on the hands and heels which gave rise to a suspicion of scarlet fever—one after ten days in hospital without fever or rash and the other shortly after removal on account of röteln, of which there had been an outbreak in the hospital. The other 12 cases did not show this and the retention of one such case in the hospital and subsequent removal to the convalescent home did not lead to communication of scarlet fever to anyone else, so this exfoliation of the skin may be regarded as an occasional effect of the drug.

In two of the earlier cases treated, possibly owing to the physiological effect of chloretone being carried rather too far, there was marked somnolence, the child lying in any attitude in which he was placed and rousing only to take food. This passed off in a few hours on discontinuing the drug. The only other objection taken account of was the cost (4s. an ounce is somewhat expensive in hospital work), but considering the small quantity used and the comparative infrequency of the cases it is not serious and with increased demand it will no doubt be reduced.

As regards the permanency of the cure further experience is required; one of the cases cited was readmitted in about three months with a relapse, and on the other hand another was successfully treated which had relapsed after treatment by arsenic. Like the treatment of rheumatism by salicylates the effects of the specific drug requires to be followed by a tonic régime in most cases since the little patients are usually anæmic and feeble in addition to suffering from the spasmodic movements. Where endocarditis coexists salicylates can be combined with the chloretone or may be applied to the skin instead, but for the chorea itself chloretone appears to be as much a specific as the salicylates have come to be regarded in rheumatism.

"PULMONARY HYPERTROPHIC OSTEO-ARTHROPATHY" OCCURRING IN A CASE OF CONGENITAL HEART DISEASE (!).¹

BY H. BATTY SHAW, M.D. LOND., F.R.C.P. LOND.,
ASSISTANT PHYSICIAN TO UNIVERSITY COLLEGE HOSPITAL AND THE
HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST,
BROMPTON,

AND
R. HIGHAM COOPER, L.S.A.,
RADIOGRAPHER TO UNIVERSITY COLLEGE HOSPITAL AND THE
STELINA HOSPITAL FOR SICK CHILDREN.

THE patient, a young unmarried woman, aged 21 years, was recently admitted to University College Hospital under the care of Sir Thomas Barlow, to whom we are indebted for the care of the notes of the case. The patient had permission to publish the notes of the case. The patient had suffered from palpitation, breathlessness, and blueness since birth. During the last ten years she had suffered from pains in the limbs, both in the ankles and wrists and in the shafts of the long bones of the legs, more particularly after standing and walking. She had scarlet fever at the age of ten

¹ Report of a case shown at a meeting of the Clinical Society of London held on March 22nd, 1907.

of five successive weeks. Fig. 2 shows the result of this treatment. The infiltration of the palmar fascia was now limited to one band. It was previously much more diffuse. Fig. 3 shows the result after subcutaneous division of this band by one incision.

ST. GEORGE'S HOSPITAL.

A CASE OF SKIN ERUPTION DUE TO CHLORETONE.

(Under the care of Dr. ROLLESTON.)

FOR the notes of the case we are indebted to Dr. Ivor Back, house physician to the hospital.

A girl, aged 15 years, was admitted to St. George's Hospital, under the care of Dr. Rolleston, on Feb. 19th, 1907, for choreic movements of sudden onset. She was at once put on five-grain doses of chloretone three times a day, in accordance with the plan of treatment carried out by Dr. W. E. Wynter. At first its beneficial effects were most remarkable and in four days all movements had gone (Feb. 23rd). This was followed by a slight relapse; the drug seemed to lose its effect on the patient. Early in the morning of March 2nd a rash was first noticed. Up to this time the patient had taken exactly two and a half drachms (150 grains) of chloretone. When first seen the rash was distributed over the front and back of the hand and forearm, and extended upwards as far as the elbow. It consisted of a number of flat-topped papules (rather like a lichen ruber planus). They were of a bright mulberry colour, varied in size from that of a pin's head to that of a pea, and did not show any tendency to run together. They faded on pressure but quickly returned. The rash itched. The chloretone was at once omitted. On March 4th the eruption appeared on both ankles and in the sacral fold. On the 5th the eruption completely changed in character, consisting of a number of rings which were white in the centre and pink at the periphery. Their margins tended to coalesce, and it had somewhat the appearance of subsiding urticaria. The appearance of the eruption was at no time comparable to that of a rheumatic rash. On the 6th the eruption had practically disappeared. Up to the time of writing (March 28th) the patient has taken another 150 grains of chloretone, but there has been no further eruption.

Remarks.—Chloretone, or trichloroethyl-ethyl-alcohol, was recommended verbally to us by Dr. Wynter as a successful drug in the treatment of chorea, and from our experience, since his recommendation, we can confirm his good opinion. The rash resembled in a general way the eruption due to chloralamide described by Dr. P. H. Pye-Smith in Vol. XXIII. of the Transactions of the Olthical Society of London, but did not show any subsequent desquamation as in his case. Dr. Wynter has told us that desquamation may occur in patients taking chloretone without any preceding rash, and we have observed this in a patient taking chloretone for reasons other than chorea.

UNIVERSITY OF OXFORD.—In a convocation held on March 20th the degree of D.C.L. by diploma was conferred upon the Right Hon. George Nathaniel, Lord Curzon of Kedleston, M.A., Hon. D.C.L., Chancellor-elect of the University.—John Freeman, D.M., University College, has been elected to a Radcliffe Travelling Fellowship.

CORNELIA HOSPITAL, POOLE.—At the annual meeting of the subscribers of the Cornelia Hospital, which has been recently held, it was stated that there was a deficit in the accounts of £262, which Lady Wimborne has generously offered to pay off. To the funds of this institution during the past few years Lady Wimborne has contributed several thousand pounds.

Medical Societies.

MEDICAL SOCIETY OF LONDON.

The Operative Treatment of Hepatic Ascites.

A MEETING of this society was held on March 25th, Sir EDGECOMBE VENNING, a Vice-President, being in the chair.

Mr. LAWRENCE JONES read a paper on the Operative Treatment of the Ascites of Hepatic Cirrhosis. There was, he said, still much doubt as to the manner in which cirrhosis of the liver brought about ascites, and at present it seemed best to allow both portal obstruction and toxæmia as factors. Recent experiments of Herrick seemed to show that the portal obstruction was not due to pressure on the portal radicles by the new fibrous tissue but to the increased communications which formed in this disease between the hepatic artery and the portal vein, and this would account for the ascites which sometimes arose early in the course of cirrhosis. Ligature of the portal vein in animals usually failed to produce ascites, but this fact might be used against the toxæmic as well as against the obstructive origin of ascites, for the symptoms caused by ligature were those of toxæmia. On the other hand, thrombosis of the portal vein was frequently accompanied by ascites. Ascites was usually a terminal event in cirrhosis, but this was not always the case. The ideal patient for operative treatment was one who was still fairly young, with no suggestion of any other cause (such as cardiac failure) for the ascites, whose liver was in the hypertrophic stage, whose symptoms were more those of portal obstruction than of toxæmia, and who had recovered from one removal of a fluid—showing it to be of mechanical rather than of inflammatory origin. All operations aimed at the formation of fresh porto-caval communications which were usually effected by suture of the omentum to the abdominal wall. The operation might be intraperitoneal, as originally devised, or extraperitoneal, as in the operation of Schiassi, Bunge, and others. Many additions, such as hepatoptomy, splenectomy, and the formation of intestinal adhesions, had been made to the original operation or performed when simple suture of the omentum had failed or had been impracticable. There seemed no doubt as to the value in certain cases of the operation. It appeared to relieve the patient from ascites and prolonged life in comparative comfort, perhaps for some years. No improving effect on the liver itself was claimed, although sometimes the operation seemed to check the cirrhotic process. The results obtained up to the present were fatal in about one-third of the cases, marked improvement took place in one-third, and little or no benefit in the remainder. The mortality usually given was too high, for many cases were included which died two or three weeks after the operation, and this should be ascribed more to a bad selection of cases or delay until too late than to the operation itself. The direct death-rate from the operation should not be more than 10 per cent.

Mr. W. G. SPENCER dissented from some of the opinions expressed. He thought that the subject should be considered apart from the liver, simply as affecting cases of fluid in the peritoneum or as if the case were one of chronic peritonitis. Each case must, however, be dealt with on its own merits. He referred to several cases in which various other abdominal conditions had been revealed at the operation apart from hepatic disease. One case previously recorded had revealed chronic peritonitis secondary to ovarian disease. Another patient went on with her drinking habits but had had no return of the ascites. As regards the precise method of operation, the German method with a six-inch incision and complex procedure was quite unnecessary. The mortality after the simpler operation which he had usually done was very small. It was very desirable to find out the underlying cause and the operation itself was often a means of revealing this and of effecting a cure.

Dr. F. DE HAVILLAND HALL also emphasised the importance of thorough medical investigation before undertaking operation. It was particularly necessary to exclude syphilis, and reference was made to cases of this kind recorded by the late Dr. J. S. Bristowe. The injection of adrenalin into the peritoneal cavity was often efficacious. From three to four drachms of adrenalin solution injected into the peritoneal cavity after tapping was the method which Dr. de

lasting about five months. She suffered frequently from pelvic pain and occasional leucorrhœa till the present illness. Her last menstrual periods were July 12th, July 22nd, and August 12th of last year, since when she had intermittent brownish discharge and dull, aching pelvic pain. She suspected that she was pregnant. On Sept. 27th, about 8 A.M., she was suddenly seized with severe pain in the left pelvis and hypogastrium and sent for me. Examination of the breasts bore out her suspicion of pregnancy and per vaginam the true nature of the condition was diagnosed by the feeling of an hæmatocele filling the left pelvis. After rallying from this attack she, about 1 P.M., showed signs of collapse from internal hæmorrhage and consented to immediate operation. On opening the abdomen a placenta and two foetuses were found separately among a huge mass of blood clot which was rapidly removed and the ruptured tube brought up to the wound, its ends tied in one grasp of the ligature, then cut away and the stump returned to the pelvis. The peritoneal cavity was flushed out with hot saline solution, at least a quart being left in when the wound was closed. The patient was back in bed again within 20 minutes of the commencement of the anaesthetic and made an uninterrupted recovery. She remains, six months after the operation, in excellent health. In our anxiety for the welfare of the patient we unfortunately allowed the placenta to be thrown away in the process of tidying up, thus leaving the specimen incomplete but as it is it may be considered worthy of reproduction. One foetus may be seen to be still enveloped in a separate amniotic sac.

I am indebted to Mr. E. Allan for his assistance at the operation and to Mr. F. E. Daniel for photographing my gelatin preparation of the specimen.

Barrow-in-Furness.

A CASE OF SUPPURATING HYDATID OF THE GALL-BLADDER; OPERATION; RECOVERY.

BY ARTHUR G. L. READE,

SENIOR HOUSE SURGEON TO THE RADCLIFFE INFIRMARY, OXFORD.

A MAN, aged 31 years, a labourer, was admitted to the Radcliffe Infirmary and County Hospital, Oxford, under the care of Dr. W. T. Brooks, on Sept. 24th, 1906, complaining of acute abdominal pain. He had always been a healthy man until August 22nd, when he was in this hospital under the care of Mr. H. P. Symonds suffering from biliary colic. At that time his stools were white and his urine was dark brown; the conjunctivæ were yellow. There was nothing to be made out in the abdomen and, as he refused operation, in a fortnight's time he was discharged, as by that time he had recovered. He remained well until Sept. 22nd, when he was suddenly seized with sharp pain in the stomach and back which doubled him up; he vomited several times and sweated with pain. This pain had been continuous and the vomiting was so persistent that he could retain no food. The bowels were opened on the 23rd, since which date he had begun to get yellow. He had had no sleep for the last two nights on account of the pain; his urine was very dark in colour. He had never been abroad and there was nothing of importance in the family history. His condition on admission was as follows. The patient lay on his back with his knees slightly drawn up, he had an anxious expression, and his respirations were hurried. His face had a yellow tinge and the cheeks were red. His temperature was 103.8° F., his pulse was 120, and his respirations were 28; the conjunctivæ were markedly yellow and the tongue was furred. On examining the abdomen it was noticed that the skin was yellow and movement was very slight. There was marked fulness in the epigastrium. On palpation there was definite resistance in the epigastrium towards the right side and the abdomen was exquisitely tender above the umbilicus. Nothing was to be made out in the lower part of the abdomen. On percussion resonance over the upper part of the abdomen was impaired; there was liver dullness to the fifth rib. The patient had a bad night, only sleeping when under the influence of morphine; on the next morning the temperature fell to 98°, but the pulse remained 120, and a blood count showed marked leucocytosis (19,000). The patient was transferred to Mr. Symonds's care and at 3.30 on that day (the 25th) was operated on. An incision about four inches long was made to the right of the mid-line over the region of the gall-bladder and on

opening the peritoneum a little free fluid escaped. The gall-bladder was found to be distended and on opening it, the rest of the peritoneum having been packed off as far as possible, a considerable quantity of pus escaped mixed with a large number of hydatid cysts. On exploring with the finger another cyst apparently in the liver substance was opened, which also contained pus and daughter cysts. The walls of these two cavities, which had now been made one, were sutured to the abdominal wall and a drain was put in. The rest of the incision was sutured. On the next day the patient was much better and daily continued to improve, though a very large quantity of bile escaped. Three weeks later the patient was again taken to the theatre and a purse-string suture was put round the neck of the cyst, tying in a Paul's tube, which drained the bile by a piece of india-rubber tubing attached to the tube away from the wound. Ten days later this was removed and the edges of the wound were cauterised. Under this treatment the biliary fistula closed about five weeks later, and on Dec. 29th the patient was discharged cured. He had been seen since his discharge and was keeping quite well.

Remarks by Mr. READE.—There are two interesting points in this case: first that the patient had never been abroad, nor was there any clue as to how he contracted hydatid disease; and secondly, that the daughter cysts gave rise to symptoms exactly like biliary colic followed by suppurative cholecystitis, of which nature the case was considered to be until operation. While very common in the liver the literature shows that hydatid disease affecting the gall-bladder is extremely rare. I find notes of eight cases, two of which occurred in this country. Mr. E. T. Burton reports a case under Mr. H. G. Barling's care in the *Birmingham Medical Review* of October, 1897. The patient's symptoms were very similar to those in the case here recorded. The duration of the acute illness was ten days and though he was admitted with a view to operation he was too ill to stand it and died three days after admission. Post mortem in addition to the cyst in the wall of the gall-bladder several daughter cysts were found in the bladder itself. Mr. Frederick Page reports a case in *THE LANCET* of April 9th, 1898, p. 995. This patient suffered from "bilious attacks"—i.e., epigastric pain and vomiting for five years; a tumour was felt over the region of the gall-bladder, which when explored proved to be a single hydatid cyst with no daughter cysts; this was removed and the patient recovered. I am indebted to Dr. Brooks and to Mr. Symonds for permission to publish this case, but my description of Mr. Symonds's operation has not had the great advantage of his corrections.

A CASE OF DUPUYTREN'S CONTRACTION TREATED WITH FIBROLYSIN.

BY W. DUNCAN LAWRIE, M.D. EDIN., F.R.O.S. EDIN.,

HONORARY SURGEON TO THE BIRMINGHAM CRIPPLED CHILDREN'S UNION.

The following case may perhaps claim to be of sufficient interest to be recorded in *THE LANCET*.

The patient, a man, aged 42 years, came under observation in November, 1906. The three illustrations here given speak

FIG. 1.

FIG. 2.

FIG. 3.

for themselves and thus obviate the necessity for a detailed description of the case. Fig. 1 shows the condition at the commencement of treatment. The patient could only come for treatment at the week ends and accordingly the contents of one of Merck's ampullæ containing 2.3 cubic centimetres of fibrolysin were injected on Saturday, Sunday, and Monday

of five successive weeks. Fig. 2 shows the result of this treatment. The infiltration of the palmar fascia was now limited to one hand. It was previously much more diffuse. Fig. 3 shows the result after subcutaneous division of this band by one incision.

Medical Societies.

MEDICAL SOCIETY OF LONDON.

The Operative Treatment of Hepatic Ascites.

A MEETING of this society was held on March 25th, Sir EDGEMOND VENNING, a Vice-President, being in the chair.

Mr. LAWRENCE JONES read a paper on the Operative Treatment of the Ascites of Hepatic Cirrhosis. There was, he said, still much doubt as to the manner in which cirrhosis of the liver brought about ascites, and at present it seemed best to allow both portal obstruction and toxæmia as factors. Recent experiments of Herrick seemed to show that the portal obstruction was not due to pressure on the portal radicles by the new fibrous tissue but to the increased communications which formed in this disease between the hepatic artery and the portal vein, and this would account for the ascites which sometimes arose early in the course of cirrhosis. Ligature of the portal vein in animals usually failed to produce ascites, but this fact might be used against the toxæmic as well as against the obstructive origin of ascites, for the symptoms caused by ligature were those of toxæmia. On the other hand, thrombosis of the portal vein was frequently accompanied by ascites. Ascites was usually a terminal event in cirrhosis, but this was not always the case. The ideal patient for operative treatment was one who was still fairly young, with no suggestion of any other cause (such as cardiac failure) for the ascites, whose liver was in the hypertrophic stage, whose symptoms were more those of portal obstruction than of toxæmia, and who had recovered from one removal of a fluid—showing it to be of mechanical rather than of inflammatory origin. All operations aimed at the formation of fresh porto-caval communications which were usually effected by suture of the omentum to the abdominal wall. The operation might be intraperitoneal, as originally devised, or extraperitoneal, as in the operation of Schiassi, Bunge, and others. Many additions, such as hepatoxy, splenoxy, and the formation of intestinal adhesions, had been made to the original operation or performed when simple suture of the omentum had failed or had been impracticable. There seemed no doubt as to the value in certain cases of the operation. It appeared to relieve the patient from ascites and prolonged life in comparative comfort, perhaps for some years. No improving effect on the liver itself was claimed, although sometimes the operation seemed to check the cirrhotic process. The results obtained up to the present were fatal in about one-third of the cases, marked improvement took place in one-third, and little or no benefit in the remainder. The mortality usually given was too high, for many cases were included which died two or three weeks after the operation, and this should be ascribed more to a bad selection of cases or delay until too late than to the operation itself. The direct death-rate from the operation should not be more than 10 per cent.

Mr. W. G. SPENCER dissented from some of the opinions expressed. He thought that the subject should be considered apart from the liver, simply as affecting cases of fluid in the peritoneum or as if the case were one of chronic peritonitis. Each case must, however, be dealt with on its own merits. He referred to several cases in which various other abdominal conditions had been revealed at the operation apart from hepatic disease. One case previously recorded had revealed chronic peritonitis secondary to ovarian disease. Another patient went on with her drinking habits but had had no return of the ascites. As regards the precise method of operation, the German method with a six-inch incision and complex procedure was quite unnecessary. The mortality after the simpler operation which he had usually done was very small. It was very desirable to find out the underlying cause and the operation itself was often a means of revealing this and of effecting a cure.

Dr. F. DE HAVILLAND HALL also emphasised the importance of thorough medical investigation before undertaking operation. It was particularly necessary to exclude syphilis, and reference was made to cases of this kind recorded by the late Dr. J. S. Bristowe. The injection of adrenalin into the peritoneal cavity was often efficacious. From three to four drachms of adrenalin solution injected into the peritoneal cavity after tapping was the method which Dr. de

Havilland Hall commonly adopted. The operative procedure adopted by his colleague Mr. Spencer had a very low mortality and was attended with excellent results.

Dr. F. PARKES WEBER drew attention to the importance of temperature records being carefully made before operation. Many syphilitic cases were attended by an intermitting pyrexia, which disappeared under mercury and iodide of potassium. He also emphasised the value of the part which inflammation played in producing a favourable result.

Mr. A. E. J. BARKER also referred to the fallacy of syphilitic affections of the liver. In regard to the method of operation he emphasised the importance of producing firm and enduring adhesions; these were very difficult to accomplish under modern aseptic methods. Adhesions in these circumstances disappeared, as shown by successive operations on the same patient. On these grounds he advocated the extraperitoneal operation.

Mr. H. J. WARING believed that the best results were obtained when the operation was done as early in the stage of the disease as possible. He also discussed the significance of hemorrhoids as proving the existence of definite portal obstruction. The best surgical measure, in his opinion, was to insert a portion of the great omentum into the sheath of the rectus abdominis muscle.

Dr. J. F. H. BROADBENT believed that it was better to wait until the abdomen had filled the second time. The choice of the case was important. Some cases of cirrhosis appeared to be independent of alcoholism. Very advanced cases, where the liver substance was in great part destroyed, were certainly not amenable to operative treatment.

Dr. F. J. POYNTON referred to a case of multiple inflammation of the serous membranes and asked whether any operation was available for such cases.

Mr. JONES, in reply, did not think that any operation was of use unless portal obstruction was definitely present.

CLINICAL SOCIETY OF LONDON.

Clinical Evening.

A MEETING of this society was held on March 22nd, Mr. H. H. CLUTTON, the President, being in the chair.

THE PRESIDENT exhibited a case of Congenital Hypertrophy or Giant Growth of the Feet in a girl, aged 17 years, who was otherwise quite normally developed. The deformity, which was noticed by the mother at birth, slowly increased up to the age of 14 years. During the last three years the growth had been much more rapid, producing particularly a greater inequality in the length of the two lower extremities. The feet were enormous but were fairly equal in size, the distal parts being rather larger than the proximal. No cause could be assigned. The President proposed to do a Chopart's operation on the shorter leg and a Syme's operation on the longer.

Dr. H. BATTY SHAW and Mr. R. HIGHAM COOPER showed a case of "Pulmonary Hypertrophic Osteo-arthritis" occurring in a Case of Congenital Heart Disease. The paper is published on p. 880.—Dr. A. E. GARROD referred to cases of osteo-arthritis associated with cirrhosis of the liver.—THE PRESIDENT suggested that the clubbing of the fingers represented the same process as osteo arthropathy.—Mr. W. G. SPENCER was not quite satisfied as to the existence of joint lesions in this case.

Dr. F. W. FORBES-ROSS exhibited a case of Operation after Rupture of a Pancreatic Cyst. The patient was a man, aged 71 years, suffering from prolapse of the rectum, who was suddenly seized on Oct. 17th, 1906, with pain in the left hypochondrium, shortly after which a tumour appeared in the same region, presenting a notched border. Abdominal abscess was diagnosed and two and a half quarts of pus were evacuated.

Dr. G. A. SUTHERLAND exhibited a case of Osteogenesis Imperfecta (? Syphilitic) occurring in a male infant, aged eight weeks, a first child. He was born after an easy labour and "the left wrist was seen to be broken and the arm to hang as if dislocated; the thigh and leg bones on the left side were broken." Multiple fractures in the long bones were shown in a skiagram taken seven days later. No fresh fractures were observed to occur. The child seemed to suffer great pain whenever his limbs were touched and cried for hours after he was born. At birth a lump was also noticed on the right side of the head. There was nothing of importance

in the family history. On admission, four weeks ago, great pain and tenderness were present in the extremities, which presented periosteal swelling, especially around the epiphyses. A condition of pseudo-paralysis existed, movement being limited to the fingers and toes. Signs of fracture were manifest in all the long bones of the extremities and in many of the ribs. A swelling was present over the right parietal bone with a large irregular gap in the osseous tissue. There was general peeling of the skin over the trunk and extremities. The pain and tenderness in the limbs passed off, the periosteal swelling subsided, and the infant now moved the limbs freely. Marked deformities had resulted from the fractures which were now apparently united. Mercurial treatment had been carried out.—In discussing this case Dr. LEONARD G. GUTHRIE showed skiagrams exhibiting fractures of both femora and other bones in an infant under his care who died at the age of three months. Extreme tenderness and swelling had been noticed in the fractured limbs a week after birth. At the age of one month the cranial bones were thin and widely separated, and severe ophthalmia and a well-marked syphilitic eruption on the buttocks were present. Under mercurial treatment these symptoms had improved, but the infant died from marasmus. Post-mortem examination showed that all the fractures had united but with much deformity and with no ensheathing callus. This case, like Dr. Sutherland's, was syphilitic, but Dr. Guthrie doubted whether syphilis was the invariable cause of osteogenesis imperfecta. Might not imperfect osseous development be comparable to congenital myopathy? In congenital cases he thought that the fractures were sustained during pressure at birth and not during intra-uterine life. But there were other cases in which fragilitas ossium seemed to be acquired, the fractures not appearing until after a year or two of life. In one such case, a child, aged two and a half years, was found after death to have most of the long bones fractured, and the mother was charged with murdering the child. She was acquitted, however, on the strength of the medical evidence that fragilitas ossium rather than direct violence adequately accounted for the fractures.—Mr. SPENCER suggested that the condition might be due not to disease but to an arrest or delay of development; the skiagrams shown resembled those of a fetus at about the sixth month. If this were so, later improvement might be wrongly attributed to mercurial treatment.—Dr. SUTHERLAND, in reply, said that in his opinion the present case was probably syphilitic; there was periosteal thickening about the epiphyses, the spleen was large, there was ulceration about the anus, and the case had responded to mercury. This case, therefore, should not be placed in the idiopathic but in the syphilitic group of osteogenesis imperfecta.

Mr. A. H. TUBBY showed a case of Facio-hypoglossal Anastomosis for Post-operative Paralysis occurring in a male patient, aged 19 years. An abscess was opened on April 27th, 1905, and when he recovered from the operation he found the left side of the face paralysed. On admission to Westminster Hospital there was facial palsy and the patient had lost all taste on the anterior part of the left side of the tongue. On Oct 16th an anastomosis was carried out. An incision was made with a tenotomy knife deeply into the hypoglossal nerve and the distal end of the facial nerve was implanted into it laterally. On Oct. 23rd it was noted that the palpebral fissure was lessened in size and the eye could be temporarily closed. On Oct 28th the patient began to move the left angle of the mouth. At present movement was almost perfect; there was slight atrophy of the left side of the tongue.

Mr. TUBBY also showed two cases illustrating the Treatment of Complete Paralysis of the Gastrocnemius and Soleus, with Talipes Calcaneus, by Nerve Grafting. The patients were both aged nine years and had old-standing poliomyelitis. The nerve branches to the muscles had been isolated and implanted into the external popliteal nerve. The results were excellent.—Mr. SPENCER thought that physicians should decide on a limit beyond which spontaneous recovery was impossible and then call in a surgeon.—Mr. TUBBY said that the distinction was not always clearly made between the direct effect of muscular paralysis and the secondary effects of contractures. If this were done surgical measures would often be resorted to earlier.

Mr. TUBBY also exhibited a case of Congenital Dislocation of the Hip.

Dr. F. PARKES WEBER showed a case of Acute Thyroid Swelling, with Acute Hamorrhagic (Edema of the Right

le of the Pharynx and Larynx, occurring in a male patient, aged 54 years. He had been under treatment for interstitial nephritis and had a blood pressure of 100 millimetres. On the afternoon of March 4th, the neck had suddenly begun to swell. On admission to the German Hospital at 7 P.M. the whole thyroid and, especially the right lobe, was much enlarged, tense, and tender. There was likewise considerable general swelling of the neck and over the upper part of the sternum there was great oedema of the right side of the pharynx and larynx. The pharynx was scarified and the patient was much relieved by a morphine injection, rest in bed, and the external application of ice to the neck. The swelling gradually subsided. At present (March 17th) the man felt most in his usual condition but the thyroid gland was enlarged and the skin of the neck and the upper front part of the chest was discoloured, as from extensive bruising, and there was still much ecchymosis of the mucous membrane of the pharynx and larynx.—Dr. DAVID FORSYTH said that the anatomical structure of the thyroid gland made it improbable that a hæmorrhage occurring therein would produce symptoms such as those described, but Dr. WEBER replied that an effusion must have taken place into the thyroid.

Mr. H. BETHAM ROBINSON showed a case of Enlargement of the Clavicle and Lower Jaw. The patient was a boy, aged 13 years, with chronic inflammatory swelling of the right clavicle and the left side of the lower jaw dating from fall six months before. There was some nodular enlargement of the right half of the thyroid gland. There had been some reduction in size under iodide of potassium.

Dr. HARRY CAMPBELL showed a case of Disappearance of the Subcutaneous Fat above the Region of the Lower Extremities occurring in a woman, aged 21 years. The disappearance was especially marked in the face, chest, and abdomen, including the region of the mons Veneris. There was no disappearance of fat from the mammary glands or the orbits. There was an abundant deposit of subcutaneous fat in the buttocks and lower extremities generally. The patient was said to have been perfectly normal up to the age of seven years. From this time until the age of 14 years there occurred a gradual disappearance of fat from the affected regions.—The PRESIDENT compared the condition to morphia.

Mr. DONALD J. ARMOUR showed a woman, aged 29 years, from whom a large Polycystic Kidney had been removed two and a half years previously. She had been quite unaware of her tumour and there had been no urinary symptoms.—Dr. ARTHUR WEBER referred to a recent case in which a French surgeon had removed what he took to be a cystic kidney but which proved at the necropsy to be a polycystic pararenal growth of Wolffian origin.

Mr. SPENCER showed a case of Obliteration of Bilateral Psoas Abscesses. The patient, a woman, aged 25 years, had recovered, apparently completely, after several operations.—Mr. WARREN LOW referred to the advantages of closing the wound after operation in such cases.—Mr. SPENCER, in reply, said that it was at first impossible to do so in this case, as the sac was already septic when he first saw the patient.

Mr. A. E. J. BARKER showed a case, in a woman, aged 24 years, of Fixation of the Jaw. The left masseter was fibrous.—The PRESIDENT noted the elongation of the lower jaw and suggested alveolar trouble as the cause of the condition.

OPHTHALMOLOGICAL SOCIETY.

Thrombosis of the Cavernous Sinus.—Sympathetic Irritation.—Cysts of the Pars Ciliaris Retina.—Exhibition of Cases and Specimens.

A MEETING of this society was held on March 14th, Mr. PRIESTLEY SMITH, the President, being in the chair.

Dr. W. O. ROCKLIFFE (Hull) read notes of a case of Thrombosis of the Cavernous Sinus associated with Meningitis, originating in a septic sore on the upper lip. The patient was a fish-dock labourer whose general health but for occasional bronchitic attacks had been satisfactory. When first seen on Nov. 18th there was proptosis on the right side, with fixation of the globe, swelling of the lids, and chemosis. Five days previously a small pimple had appeared on the right side of the upper lip, which had been picked and eventually pricked with a pin. The lip and face became greatly swollen and were subsequently treated with a linseed-meal poultice. During the two days the patient was in the infirmary there

was delirium and the temperature ranged from 102° to 105° F. A lumbar puncture was made and cocci were identified in the leucocytes. Cultures proved the infection to be staphylococcus pyogenes aureus both in the spinal fluid and lip. Death occurred on Nov. 20th, two days after admission and seven days after the spot appeared on the lip. At the necropsy the meninges about the cavernous sinuses were covered with lymph. The right and part of the left cavernous sinus and the transverse sinus were thrombosed. The orbital tissues on the right side were inflamed and swollen, but there was no pus. The case differed from one of cellulitis of the orbit, which did not tend to affect the opposite side.—Mr. J. B. LAWFORD cited a somewhat similar case of cavernous thrombosis in a man, aged 36 years, which resulted from a pustule in the nostril. There was cellulitis of the nose, face, and orbit. Death occurred in four days, though antistaphylococcal serum was given.

Dr. ROCKLIFFE also recorded four cases of Sympathetic Irritation occurring 18, 22, 28, and 50 years after injury to the other eye. In two of these cases a foreign body was found and a fragment of stone was probably present in the eye in the third case, the fourth being a punctured wound. Considerable ossification of the choroid was present in three.—Mr. E. TREACHER COLLINS commented on the wide field of discussion opened up by Dr. Rockcliffe's communication. He thought that three of the cases were rather of the nature of sympathetic inflammation than irritation on account of the presence of keratitis punctata. In the other, glaucoma occurring in the second eye might be attributed to the shock of excision, as it not infrequently followed this. In reference to the specimens shown he said that ossification of the iris was unknown, though such change might occur in the adjacent choroidal processes or the capsule of the lens.

Mr. A. R. BRADLEY read a paper on Cysts of the Pars Ciliaris Retina and stated that clinically these structures had frequently been mistaken for sarcomata of the ciliary body, but little was known of their pathology, though their study might throw some light on the secretion of the aqueous fluid. They were found in such a variety of conditions that he was only able to classify them according to their apparent mode of origin. Two changes which played an important part in the origin of some varieties limited to the cells of the non-pigmented epithelium were multiplication of the cells and vacuolation of the cell bodies. This proliferation was most frequently found in senile eyes and was commonly associated with hypertrophy of the ciliary processes. The cells of the pigmented layer appeared to play a mere passive rôle, and even in cysts arising by simple detachment of the epithelium it was the unpigmented layer alone which was affected; the adhesion between the pigmented epithelium and the underlying ciliary body being a peculiarly intimate one. The different modes of origin appeared to be: (1) detachment of the non-pigmented epithelium; (2) proliferation of the non-pigmented epithelium cells, with the formation of a cavity arising either by a simple separation of the cells or by their vacuolation and destruction; and (3) proliferation and union of the cells of adjacent processes, leading to a portion of the posterior chamber being shut off from the remainder. The number of the specimens was too small for him to come to any conclusion as to the relative frequency of these varieties. The contents of the cysts were usually lost during the preparation of the specimen, but when present they consisted of a deeply-staining, homogeneous, coagulable fluid.

The following cases and card specimens were shown:—

Mr. F. F. BURGHARD and Dr. E. L. PRITCHARD: Cavernous Sinus Aneurysm cured by a new method after failure of the usual operation.

Mr. G. COATS: A case of Orycephaly.

Mr. L. J. PATON: Orycephaly.

Mr. W. I. HANCOCK: Peripapillary Atrophy.

Mr. COLLINS: A Corneal Affection in Myxœdema.

Mr. H. B. GRIMSDALE: Unusual Opacity in the Lens.

Dr. ROCKLIFFE: A Completely Calcareous Lens; Totally Ossified Iris (1).

LIVERPOOL MEDICAL INSTITUTION.

Exhibition of Cases.—The Treatment of the Acute Pathogenic Infections with Vaccines and Sera.

A MEETING of this society was held on March 21st, Mr. FRANK T. PAUL, the President, being in the chair.

Many cases of interest were shown, among them being:

Medical cases by Dr. A. G. GULLAN, Mr. F. A. POND, Dr. NATHAN RAW, and Dr. R. G. WILLIS; Surgical cases by the PRESIDENT, Dr. DAVID MORGAN, and Mr. K. W. MONSARRAT; Skin cases by Dr. H. LESLIE ROBERTS, Dr. F. H. BARENDT, Dr. G. G. S. TAYLOR, Dr. R. W. MACKENNA, Dr. W. O. ORAM, and Dr. E. L. ANDERSON; Eye cases by Dr. K. A. GROSSMANN, Mr. R. J. HAMILTON, Dr. W. E. LIVSEY, and Dr. A. N. WALKER; and Ear cases by Mr. E. M. STOODALE.

The PRESIDENT showed the following cases: 1. A boy, aged 11 years, who had been scalded when two years old on the Side of the Chest. Subsequently the mother noticed a swelling in the region of the left pectoral muscle. This had gradually grown until it was now of the size of a hen's egg. It had been examined and found to consist entirely of muscle. 2. A case of Immense Hypertrophy of the Gums of Both Jaws, shown previously before the society and now cured. The gums were removed by four operations two years ago without extracting the teeth, and recurrence had taken place. A second series of four operations was undertaken with removal of the entire alveolar processes resulting in complete cure. (Models of the original condition were shown by Mr. F. J. M. PHILLIPS, dental surgeon to the Royal Infirmary). 3. A woman, aged 53 years, who had received an Injury to the Fifth and Sixth Cervical Nerves from a fall on the shoulder causing paralysis of the muscles supplied by those nerves.

Dr. RAW read a paper on the Treatment of the Acute Pathogenic Infections with Vaccines and Sera. He particularly mentioned the great value of antidiphtheritic serum if given early in pure cases of diphtheria but said that in mixed infections it did not seem to exert the same beneficial influence. He had treated 212 cases of erysipelas, puerperal fever, and other septic infections with antistreptococcal serum and was convinced that in streptococcal infections the serum if given early had a marked curative effect. The use of a polyvalent serum had immensely improved the results of treatment. In the treatment of a large number of cases of tuberculosis he had come to the conclusion that tuberculin R. had not much curative value in phthisis pulmonalis, even in the early stages of the disease, but in the so-called surgical forms of tuberculosis, such as lupus, tuberculous glands, joints, and peritonitis, tuberculin R. had a most marked curative effect and his results of treatment of numerous such cases were astonishingly good. He was not favourably impressed with the value of antitetanic serum.—Dr. W. B. WARRINGTON considered antistreptococcal serum to be of little utility in medicine and pointed out that it was the recognition of this that led Sir A. E. Wright to introduce the method of vaccines. He alluded to the value of endoneural injection of the antitoxin in tetanus.—Dr. ERNEST E. GLYNN, commenting upon the very favourable results obtained by Dr. Raw with antistreptococcal serum in puerperal septicæmia, asked what evidence there was that the cases were true septicæmia and also due to streptococci, as cultures were not made in the majority of instances. Might not many have been cases of intoxication and recovery been the result of local treatment of the uterus? Dr. Raw's success in treating lupus with tuberculin uncontrolled by the opsonic index and unassisted by light treatment was not in accord with the experience of many, for lupus was very refractory. He was also surprised that Dr. Raw had cured three cases of tuberculous meningitis with tuberculin, especially as the opsonic index had not been taken.—Dr. A. S. PARKINSON said that the earlier tuberculin was given in pulmonary tuberculosis the greater the probability there was of a good result. He thought that the failure in advanced cases was sometimes due to secondary infection of the lungs by pyogenic organisms, and that the immunity of such patients against secondary infections should be raised as well as the treatment by tuberculin injections carried out.—The following gentlemen also took part in the discussion: Dr. TAYLOR, Dr. J. HILL ABRAHAM, Dr. B. SUMNER, Dr. N. E. ROBERTS, Dr. R. J. M. BUCHANAN, and Dr. ORAM.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF OBSTETRICS.

Exhibition of Specimens.—Pubiotomy (Hebotomy).

A MEETING of this section was held on March 8th, Dr. R. D. PURKFOY, the President, being in the chair. Dr. ALFRED J. SMITH exhibited a Uterus showing a Fibromyoma in the Fundus and Cancer in the Cervix. The patient

was 40 years of age. Dr. Smith had diagnosed and discovered polypus of the uterus and had made up his mind to remove it as the cause of the hæmorrhage from which the patient suffered. During the removal of it he found an ulcerated spot in the cervix which under the microscope proved to be an adeno-carcinoma.—Sir ARTHUR V. MACAN said that the specimen was interesting as showing two things which were extremely rare in combination, though neither was rare by itself.

Sir ARTHUR MACAN exhibited specimens of Carcinoma and of Sarcoma of the Body of the Uterus. One of the patients was 50 and the other was 60 years of age.

Mr. E. HASTINGS TYRREDDY, Master of the Rotunda Hospital, Dublin, described a case in which he had delivered a primiparous woman of a living child at full term through an internal conjugate measuring 6.5 centimetres by the performance of a left-sided hebotomy. Hæmorrhage had been very severe and had resulted in a considerable degree of collapse. Delivery had to be hastened because of prolapse of the cord, which took place before the operation was undertaken. Deep lacerations of the cervix, of the soft parts lying between the severed bone, and of the perineum occurred, requiring catgut sutures. The patient's recovery was uneventful and she left the hospital in perfect health the ninth week with a living child.

Dr. M. J. GIBSON read a paper on Pubiotomy, with Note on Three Cases. He said that the idea of improving the prognosis for the mother and child in cases of contracted pelvis, and of lessening the number of Cæsarean section inductions of premature labour, and perforations of the live child, by an artificial enlargement of the pelvis was a very old one. Symphysiotomy, first demonstrated by COURVILLE in 1655, was first performed on the living subject by Sigault 10 years later. Symphysiotomy was not a very satisfactory operation. To Gigli belongs the honour of being the first to propose as a substitute for it an incision through the pubis. The great danger in Gigli's operation lay in the large easily infected incision which he employed. Döderlein's subcutaneous pubiotomy was really a new operation, at once simple and effective. It was indicated in cases of narrow pelvis when the cervix was fully dilated and when, in spite of good contractions, the head moved freely about the brim. Good uterine contractions might by preparation of the maternal soft parts and by moulding of the fetal head drive the latter through a pelvis so narrow that natural delivery could hardly have been expected. The operation might be performed in cases of flat pelvis with a conjugata vera up to 6.75 centimetres, and in generally contracted pelvis up to seven centimetres, but for these very low conjugates the head must not be larger or harder than normal. He adopted Döderlein's method in his cases. A small incision, sufficient to admit a finger, was made over the bone, usually at the left side between the symphysis and the tubercle. Döderlein's needle was passed down behind the bone and its point brought out in the greater labium. Gigli's saw was attached and the bone divided. The hæmorrhage was as a rule easily stopped by compression. The patient should not be delivered except it was absolutely indicated. After labour was completed a few strips of adhesive plaster were put around the pelvis, a binder was applied, and the patient was kept lying on her back for 12 days. She might get up on the fourteenth or sixteenth day. The advantages over symphysiotomy were that the undivided soft parts prevented the pelvis from springing suddenly apart, while the bladder and urethra were not so liable to injury during the operation. The operation was also more easily and more rapidly performed. He performed his first operation on August 16th, 1906; the patient was 34 years of age and had been pregnant nine times but had no living child. Premature labour had been induced twice. The pelvis was generally contracted with a true conjugate of eight centimetres. A child weighing 12 pounds was delivered without difficulty. The patient was walking about on the twenty-first day, and left the hospital with her child two days afterwards in perfect health. The second patient was 32 years of age and had also been pregnant nine times. Her second child was delivered with forceps and was still alive. She had premature labour induced three times. In her last pregnancy she went into hospital after being in labour for 14 hours. The cervix was fully dilated, the membranes were ruptured, the fetal head was small and was free above the brim. The pelvis was generally contracted and flat with a conjugate of 7.5 centimetres. The fetal pulse-rate reckoned from the heart sounds was about 160, but was very irregular. Meconium came away in large quantities. The mother

in pneumonia and was in a very bad condition. Pubiotomy performed and a child weighing six pounds was extracted by forceps. The mother had her crisis on the ninth day. She left hospital on the twenty-fourth day in good condition. The third patient was a tripara, aged 29 years. Her second child was delivered with forceps, weighed 5½ pounds, and was still alive. The pelvis was rachitic and flat; the jugata vera measured seven centimetres. A child which transversely was easily delivered by podalic version after lotomy was performed. It weighed 7½ pounds. The three infants were breast-fed. None of the women complained of or showed any difference from a normal confinement, except, of course, the second one, who was suffering from pneumonia. The maternal mortality so far was about 3 per cent. thought that there was a great future for this operation that it would never share the fate of symphysiotomy but would remain a means of overcoming the difficulties connected with the lesser degrees of contraction of the pelvis without injury to the mother or child.—Sir ARTHUR MACAN said that he had seen pubiotomy performed with ease by an operator who had never done it before. There was nothing in it which could not be done by a man who had been through the Dublin school. By its use a practitioner in the country might save both mother and child in cases where he had put on the forceps and failed and was face to face with perforation.—THOMAS NEILL said that with this operation the risk of infection would be less than in the induction of premature labour.—Dr. HENRY JELLET said that it seemed to him to be doing Cæsarean section on a perfectly healthy patient, weakened by the long continuance of labour, they were not certain of the after results. On the other hand, he certainly agreed that, in cases where the forceps had been tried and failed, pubiotomy had got its place and would keep it. The ease with which it was performed, the small amount of assistance required, the small extent of the wound, and the short time in performance, were all important factors in producing a small mortality.—PRESIDENT said that he could not see how pubiotomy did take the place of Cæsarean section in certain cases. thought that its danger had perhaps been passed over too lightly. The danger of injury to the bladder had been amply illustrated by recorded cases. The danger of hæmorrhage, he thought, was considerable, since a fatal case had been reported from Vienna. He could not help wondering after the locomotive powers of the patients had been exhausted afterwards in all cases, or whether sufficient rest had elapsed to enable an opinion to be formed on the subject. He agreed, however, as to the value of the procedure.—TWEEDY, in reply, said that while both symphysiotomy and pubiotomy had come to stay he did not think that either of them would prove a panacea. He had performed both operations with equal ease.—Dr. GIBSON, in reply, said that regarding the chance of injuring the bladder it must be remembered that in pubiotomy the pelvis was well protected by the undivided soft parts. The bladder was never so directly connected with the pubic bone that any tearing could result from the small amount of stretching undergone, even when owing to a previous puerperal sepsis there were adhesions between the bladder and the bone. This occurred rarely. A French author had stated that the ends of the bone could separate up to eight centimetres without injury to the bladder or articulations. If bleeding could not be stopped by compression the practitioner could open the wound and find where the bleeding was coming from. Pubiotomy was, he believed, a safer operation than Cæsarean section up to a certain point—i.e., a pelvis with a conjugate diameter measuring above 8.75 centimetres. The latter was never done at the beginning of labour, therefore there was no chance of seeing what the contractions would do, and no way to know well it was done there were cases on record where the cicatrix gave way afterwards. In both operations the perineal aseptically union would be equally good, but danger to the bladder and urethra was much greater in symphysiotomy than in pubiotomy and the former was also a more difficult operation and therefore not so well suited for country practitioners.

Tuberculosis by Marine Climates and began with some general remarks on sea air, sea water, sea bathing, sea voyages, and the pharmacology of the sea, and with a brief reference to Quinton's subcutaneous sea-water infusions. Ocean climate, he said, differed from all others in its exclusively marine character and its equability in contrast with the sea-coast climates, which were the most variable and offered endless combinations between the features of the coast and those of the sea, none of them being necessarily the ideal one for consumption. The effects of the seaside and sea air were mainly dependent on the patient's power of "reaction" on the one hand, and on the other hand upon the all-important effect upon the tendency to catarrh. Touching the forms of tuberculosis Dr. Nathan Raw had recently urged an etiological and clinical distinction between the infection from the "bovine" bacillus and that from the "human" bacillus which agreed well enough with their climatological data and practice, all ascribedly "bovine" infections (surgical, glandular, scrofulous, cutaneous, serous, and visceral, other than pulmonary) being almost unreservedly benefited by the sea. This was not always the case with the pulmonary affection for which alone the "human" bacillus infection would be to blame. The multiple types evolved by individual predispositions (constitutional, organic, and functional) fell into the two groups of uncomplicated tuberculosis and of catarrhal tuberculosis or phthisis pulmonalis. In the first group tuberculosis might be "latent" and healing or "declared" and spreading. In the second (which included the acute caseous form) catarrh was the chief agent of mischief as well as the first object of climatic treatment. To describe as "consumptives" the bearers of latent and spontaneously healing tubercles would be inaccurate; and, on the other hand, "tuberculosis" did not depict the varied miseries of catarrh, of pneumonia, and of caseation in the painful record of advanced consumption. Bacillary infection ("tuberculosis") might mean little or much damage and "consumption" (or in the Greek vernacular "phthisis") was always a big affair and in pathology it spelt "catarrh." They now had to reverse the famous dictum of Niemeyer and to recognise that "the worst fate that can befall the patient infected with tubercle is that he should develop phthisis." The aërotherapeutics of tuberculosis were thus, practically speaking, those of catarrh. But whereas sea air was curative of some forms of simple non-bacillary bronchitis it was not always sufficiently dry for the cure of catarrh based upon tubercle. Whether they considered the meteorological factors or were guided by the results observed clinically it could not be gainsaid that the altitude was likely, and proved itself, to be more effectual in obviating early catarrh and curing it at any of its stages than the climate of the coast. But as they had not any altitudes available in this country they should adopt an opportunist policy and make the most of their unrivalled assortment of "protecting" and "bracing" seaside resorts by careful selection of cases, by progressive elaboration of their clinical treatment, and by measures tending to correct any imperfections of the local climates. The "bracing" resorts possessed the highest restorative efficiency, but their suitability for pulmonary tuberculosis was limited. The present position of the treatment by marine climates rested upon the recognition of the fact that mere "airing" and "salting" were not competent in themselves to cure the pulmonary complications of the disease when it affected the lungs. "Open air" and "sea air" were a basis for treatment, but could not supersede the scientific methods of modern therapeutics. The marine resorts should add to their natural resources increased facilities for a systematic treatment planned upon a combination of the hospital idea and of the sanatorium idea.—Mr. Henry Colborne (St. Leonards-on-Sea) read a statistical paper in which some facts and figures were set forth as to the temperature, rainfall, bright sunshine, and climatic conditions of Hastings, covering a considerable period.—Dr. A. Scarslyn Wilson (St. Leonards-on-Sea) said that examination of the mortality statistics showed that since 1898 there had been a marked decline in the number of deaths from phthisis registered in Hastings. This reduction was so great (nearly 35 per cent. comparing 1898 with 1906) as to make it reasonable to infer that the stream of phthisical patients which formerly flowed in this direction had been partially diverted into other channels, probably towards the inland sanatoriums which had recently sprung up. If other seaside resorts had been similarly affected a great change must have taken place.

the medical profession as to the value of marine stations in the treatment of active phthisis.—Dr. D. Anderson-Berry (St. Leonards-on-Sea) wished to emphasise certain points: (1) that there was no single method whereby phthisis might be successfully treated; drugs had their place as well as open air and other hygienic methods; and (2) that the patients who did well at marine stations were those whose opsonic index showed a considerable power of reaction present, especially when tested by injections of tuberculin. In answer to a question asked he would add that such a climate as that of St. Leonards was especially favourable in his experience to cases of emphysema upon which had been grafted tuberculous processes.—Dr. F. Bagshawe (St. Leonards-on-Sea) pointed out that Dr. Henry Bennet was an early advocate of the treatment of phthisis by the open-air method. All his patients at Mentone were enjoined to have their windows open night and day and to spend much time reclining in the garden. The importance of rest was especially enjoined. Looking back upon an experience of 40 years at Hastings he was able to point to a long list of patients who had lived through the active stages of pulmonary tuberculosis and had settled down to spend long lives, with arrested damage, some partially, some entirely, cured.—Mr. George Pernet (London) desired to call attention to the importance of general treatment in tuberculosis of the skin, especially as regards marine climates.—Dr. F. J. Wethered (London) said that it might be accepted that the treatment of pulmonary tuberculosis in marine climates was practically one form of the "open-air" treatment of the disease, the essentials of which might be obtained *par excellence* at English seaside resorts. He laid stress on the importance of studying "individualism" in the selection of cases to be sent to marine climates.—Dr. P. G. Lewis (Folkestone) said that so long as there were consumption hospitals in congested areas, as the City-road and Brompton road in London, it would be necessary to try to convert the leaders of the profession to the imperative need for treating phthisis out of large cities. He criticised sanatorium treatment and advocated the advantages of marine climates for the treatment of most forms of tuberculosis.—Dr. Leonard L. B. Williams (London) said that sanatoriums were doing a fine work, not so much in curing phthisis as in educating the public in open-air methods. Marine climates could offer no such advantages, because climate without method was useless.—Dr. St. Clair Thomson (London) spoke in emphatic terms of the necessity of instruction concerning the open-air methods carried out in the inland sanatoriums.—Dr. W. J. Tyson (Folkestone) spoke in favour of marine climates in the treatment of tuberculosis.

MEDICO-LEGAL SOCIETY.—A meeting of this society was held on March 12th, Mr. Justice Walton, the President, being in the chair.—A discussion was held on the working of the Midwives Act, 1902.—Mr. J. Theodore Dodd (barrister-at-law) dealt with the two practical points which arose—(1) when the certified midwife was bound by her regulations to send for medical aid; and (2) the payment of certified midwives at such a rate as would attract a competent and better class of women. As to the former, it was not the duty of the medical officer of health to help at birth, and hence the necessary aid must come from the Poor-law. In principle the law provided such assistance but in practice it was difficult to obtain. Medical relief was only given to the destitute, others had to enter into an agreement to repay the cost, and for a matter of emergency the necessary proceedings were too leisurely and led to too great a delay. A letter from a certified midwife to a medical man should be a sufficient claim upon the guardians in cases of poverty. He would have midwives attached to the Poor-law medical staff as was already the case in Ireland; otherwise, to avoid the stigma of pauperism, midwives should be on the staff of the medical officer of health.—Dr. F. S. Toogood (Lewisham Infirmary) said that Poor-law guardians would object to their privileges being handed over to certified midwives; district medical officers relied upon the extra midwifery fees to make their posts worth being held and would resent the introduction of competing midwives.—Sir William Collins, M.P., said that when he was a member of the London County Council he had objected to having to fetch and carry for the Central Midwives Board, as also to allowing the cooption of irresponsible persons to the Local Government Act (Special) Committee; the local supervising myoma in the case of a woman, proper control and not anonymous

charges against midwives. The London County Council was offering annual scholarships to would-be midwives.—Miss Wilson (President of the Midwives' Institute) said that she had been on the Central Midwives Board for four years and was well acquainted with the subject. Midwives were poorly paid, their work was not peculiarly attractive, and of those who were now being examined by the Central Midwives Board at least one-half were not going to attend the poor but were intending to take up monthly nursing or other well-paid work. If only efficient midwives were available the preventive work that they could do in guarding the health of poorer mothers would obviate to a large extent the need of sending them to the local infirmary, which not also often implied robbing the home of its mainstay. It was not the function of the Central Midwives Board to regulate the supply of midwives; 12,000 certified women were in private practice in England and Wales, only one-third of whom had been properly trained. That the Poor-law could help midwives in difficulty was shown by the recent action of the guardians of King's Norton and Birmingham, who for one year had allowed midwives to summon the district medical officer without the usually indispensable order of a relieving officer. Poor-law medical officers were called in now more frequently than formerly; this was an admitted hardship where the salary was an inclusive sum. The Irish system of having dispensary (Poor-law) midwives had many advantages; although its adoption in England as it stood might not be advisable it was practical and full of suggestions.—Dr. A. H. Downes (Local Government Board), premising that his remarks were not to be regarded as in any way an official declaration, said that the first object in the working of the Midwives Act, 1902, should be to facilitate the provision of proper aid to women in labour. He was surprised to hear it stated that it was not the function of the Central Midwives Board to consider the supply of midwives; it was certainly not the province of the Local Government Board, nor was there any basis for the extraordinary misapprehension that the Local Government Board desired to establish a second standard of training for certified midwives. With regard to the provision of medical assistance in cases of difficulty, he thought that more power existed than had been suggested in the discussion. Thus, an Act of 1843 (11 & 12 Vict., c. 110, s. 2) enabled the guardians of any union, if they thought proper, to pay for any medical or other assistance rendered to any poor person on the happening of any accident, bodily casualty, or sudden illness, although no order had been given by any of their officers or by the overseers. This power had been acted upon in some unions long before there was any question under the Midwives Act, and the attention of guardians had been drawn to it by the Local Government Board on various occasions since the Act. The action of the guardians under the 1843 statute, however, was entirely discretionary; there was no guarantee that the medical practitioner would get his fee in all cases, and it was a doubtful point whether compulsory powers should be granted, in which case the State would tend to become a debt-collecting agency. In some cases sanitary authorities had availed themselves of a provision of the Public Health Acts (s. 133 of the Act of 1875; s. 77 London Act, 1891) for the furnishing, with the sanction of the Local Government Board, of temporary medical assistance for the poorer inhabitants of their district, although originally this was probably only intended to apply to epidemic disease.—The President said that he feared any change which would weaken the tie of parental responsibility; he saw also a great difference between a voluntary charity and the legal obligation to support others. It might possibly be enacted that a certified midwife should, on her own responsibility, send for a medical man in cases of difficulty: he should be paid by the guardians in necessary cases, otherwise the husband should be responsible, even although he were not privy to the contract.—Mr. Theodore Dodd, in reply, said that the Local Government Board might settle the whole question by the issue of a circular to boards of guardians and that it was not fair that women and infants should suffer and die because of a quarrel between medical men and midwives.

MIDLAND MEDICAL SOCIETY.—A meeting of this society was held on March 13th, Dr. Arthur Foxwell, the President, being in the chair.—Mr. O. A. Leedham-Green showed an example of a rare condition in a female child upon whom he had operated, with success for a Prolapsed and Inverted Bladder. The operation consisted, after the replacement of the prolapse, in

a small quantity of liquefied hard paraffin into the peri-urethral tissue at the neck of the bladder.—Dr. J. Douglas Stanley showed a case of Osteitis Deformans. The patient was a woman, aged 60 years, who had complained of pain in the back and legs for some years. There was also pain in the right knee. She noticed 18 months ago that the right leg and thigh were "getting bent" and that she was going lame. About the same time she began to stoop. On examination well-marked kyphosis was found; the right leg and thigh were bent forwards and outwards; the tibia and femur were massive, presenting the typical appearance of Paget's disease. The left femur and the right humerus were similarly affected to a slight degree. The skull showed no abnormality nor were there any signs of tumour formation.—Dr. Stanley also showed for contrast a woman suffering from Syphilitic Osteitis affecting the Right Tibia.—Dr. O. J. Kauffmann showed a man, aged 28 years, suffering from very pronounced Sclerotic Spasm, coupled latterly with frequent severe hysterio-epileptic attacks. The patient had been epileptic ever since his fifth year and until December, 1906, he had been subject to true epileptic seizures about once in every six weeks, but his mind had remained normal and he had been in regular employment as a clerk. In December he had been attacked with influenza which had kept him in bed for about a week. On the day after rising from bed the jumping spasm had begun and, despite energetic treatment by bromides, had gradually increased in strength. Five days before his exhibition the patient had suddenly commenced with violent hysterio-epileptic convulsions. At the time of his exhibition the sclerotic spasm was so intense that he was unable to stand without support. The spasm was rendered more intense by being observed and when the patient lay in bed it took the form of occasional sharp flexions of the thighs on the trunk.—Dr. J. G. Emanuel showed a girl, aged 15 years, suffering from clonic spasms of the left arm and left leg of six weeks' duration appearing after a fright caused by the barking of a dog. The movements for the most part consisted of alternate supination and pronation of the hand, combined with eversion and inversion of the foot and flexions of the trunk on the thighs. Some three years previously the patient had experienced a similar attack, lasting two or three months, also brought on by fright caused by a dog. At this time she was acquainted with another child suffering from chorea. The case was described as one of complicated habit-spasm or habit-chorea brought on by fright in the production of which mimicry apparently played a part.—Mr. J. Jameson Evans showed a woman, aged 34 years, the subject of Graves's disease, who exhibited new signs. The exophthalmos was confined to the left eye, but the pigmentation of the eyelids (Tells's sign) and marked difficulty in averting the lids (Gifford's sign) were present on both sides.—Dr. James E. H. Sawyer showed a specimen of Malignant Growth of the Heart. The patient's left leg had been amputated for an osteo-sarcoma of the lower end of the femur of four months' duration but she died three months later from secondary growths in the heart. The right auricle contained one small nodule of secondary growth. The outline of the right ventricle was irregular in shape owing to the growths in its walls and it was necessary to use a saw to open the ventricle. Most of the growth projected into the cavity of the ventricle and consisted of round hard nodules of osteo-sarcoma. Many of these growths were freely moveable, being attached to the ventricular wall by narrow pedicles. There were no deposits in the left side of the heart but there were many in the lungs and pleura.—Dr. J. Miller showed specimens from a case of Early Acute Poliomyelitis occurring in a boy, aged nine years, the total duration of whose illness was less than a week. On admission to hospital he complained of pains in the back of his neck; his legs and his abdominal muscles were paralysed and the reflexes, with the exception of the pupillary reflex, were absent. Before death the arms and the chest muscles gradually became paralysed. The necropsy revealed a softening and swelling with congestion and scattered punctate hemorrhages affecting especially the fourth, fifth, sixth, and seventh cervical segments and to a less marked extent the whole of the spinal cord. A pure growth of staphylococcus pyogenes citreus was obtained from the grey matter. Microscopically there were found dilatation of the vessels passing into the grey matter, infiltration of the perivascular lymph spaces with large numbers of cells, hemorrhages into the grey matter of both anterior and posterior horns, and degenerative changes in the cells of the grey

matter. There was no evidence of thrombosis in the vessels.

SOCIETY FOR THE STUDY OF DISEASE IN CHILDREN.—A meeting of this society was held on March 15th, Dr. G. A. Sutherland being in the chair.—Mr. Russell J. Howard read a paper on Tuberculosis of the Testis in Infants. The condition, he said, was rarer in infants than in adults owing to the period of active function not having arrived. It was rare in the undescended testis. Tuberculous peritonitis was a frequent complication. If one testis only was affected and general treatment was not successful the testis might be removed without bad effect on the mental and bodily growth, but if both testes were diseased they must only be removed as a last resource owing to the impairment of bodily and mental vigour produced by their ablation.—Mr. Howard also showed a specimen of Teratoma from the back of a child, aged six years. The tumour, five inches long, was situated on the sacrum and coccyx. It consisted of several different parts; a large structure resembling a kidney in a serous sac was below and a mass of cysts above. Bone, lymphoid tissue, and cartilage were also found. The tumour was very vascular. The large kidney-shaped mass consisted of interlacing tubules lined with a columnar-celled epithelium, with lymphoid tissue and large round cells in between the tubules. Some of the cysts were lined with stratified epithelium with sebaceous glands, others with columnar epithelium and villi. Cartilage, striped and unstriped muscular tissue, and lymphoid tissue were also seen in the section. The tumour, therefore, was derived from all three layers of the embryo and was a teratoma.—Dr. E. Cantley showed a large Abdominal Tumour in a boy, aged three years. It was probably a congenital hydronephrosis.—Dr. J. Porter Parkinson showed a case of Cerebral Tumour in a girl, aged seven years. There was a history of occasional convulsions for 18 months. Two months ago weakness of the right side of the face and the right limbs was noticed. Recently there had been headache and vomiting. There was double optic neuritis. In one fit which was observed the movements were chiefly of the right limbs. Dr. Parkinson considered that there was a subcortical tumour in the left hemisphere, probably gliomatous in nature, and proposed to have the child trephined with the object of preserving the sight.—Mr. G. Pernet exhibited a case of Multiple Lupus Vulgaris in a boy, aged ten years. The patches, which were on the chin and right shin, followed an attack of measles. They had much improved during three months' treatment by the x rays preceded by scraping.

GLASGOW PATHOLOGICAL AND CLINICAL SOCIETY.

A meeting of this society was held on March 11th, Dr. J. Lindsay Steven, the President, being in the chair.—Professor Ralph Stockman and Professor Robert Muir described a case of Lymphadenoma, with involvement of the liver and spleen, occurring in a boy, aged 14 years, who had suffered from an enlargement of various glands over a period of eight years. Enlarged glands were removed from the left side of his neck in the Glasgow Royal Infirmary seven years ago. Further enlargement took place on the same side two years later but disappeared under treatment in the Edinburgh Royal Infirmary. A year later they again became swollen and were removed at the Sick Children's Hospital, Aberdeen. Since then the remaining cervical glands had become enlarged and these had been followed by enlargement of glands in other parts of the body. At the end of September, 1906, the abdomen became very prominent and a large hard swelling appeared on the left side and cough and night sweats became troublesome. On admission to the Western Infirmary, Glasgow, in December, extreme emaciation, profound anæmia, and a general enlargement of the lymphatic glands were noted. The spleen was greatly enlarged and the liver also showed enlargement. Ascites was well marked and there was oedema of the scrotum and lower limbs. Examination of the blood showed polymorphonuclear leucocytosis and a considerable diminution in the percentage of the hæmoglobin. The patient's temperature was very variable, with evening exacerbations; his weight and strength diminished, pleural effusion and jaundice developed, and death took place on Jan. 22nd, 1907. The necropsy showed general glandular enlargement. The abdominal lymphatic glands formed a large mass and were continuous with those in the groin; enlarged glands were also present in the portal fissure. The spleen weighed nearly two pounds and distributed through it were small pale

nodules. The liver was also much altered in appearance by diffuse infiltration and a similar condition was present in the lungs. The bone marrow showed a slight hyperplasia. The microscopic appearances of the lymphatic glands showed a proliferation of the endothelial cells and of the connective tissue stroma with disappearance of the lymphoid cells from the older foci and subsequent sclerosis.

PATHOLOGICAL SOCIETY OF MANCHESTER.—A meeting of this society was held on March 13th, Dr. A. Hill Griffith being in the chair.—Mr. J. E. Platt and Dr. E. B. Leech showed microscopic slides to illustrate the Difficulty of Diagnosis of Breast Tumours. The left breast and a large axillary gland of a woman, aged 35 years, were removed for supposed carcinoma. Microscopical examination showed that the tumour in the breast was due to chronic mastitis while the axillary tumour was a fibro-adenoma and must have occurred either in an aberrant lobule or as a supernumerary breast.—Dr. J. de Ville Mather read a communication on the Pathology of Carcinoma of the Cervix Uteri. In some 47 cases of malignant disease of the cervix treated by vaginal hysterectomy the microscopical examination showed squamous epitheliomata in 37, glandular cancer in six, and sarcoma in four. Referring to sarcoma of the cervix in more detail Dr. Mather showed one case of angelo-sarcoma and another case where the growth was a mixture of round-celled sarcoma and squamous epithelioma. He did not consider sarcoma of the cervix to be as rare as was generally supposed.—Dr. John Cameron showed an Adult Brain with Complete Absence of the Corpus Callosum.—Dr. C. P. Lapage showed a specimen of Congenital Malformation of the Heart from a child aged two and a half years. The organ was twice the normal weight owing to hypertrophy of the right side. The walls of the right ventricle were thicker than those of the left and both ventricles communicated freely with the aorta owing to a deficiency of the interventricular septum. The aortic valves were normal. The ductus arteriosus supplied the lungs by the right and left pulmonary arteries. The auricles communicated by a small opening.

HARVEIAN SOCIETY OF LONDON.—A meeting of this society was held on March 7th, Dr. Sidney Phillips being in the chair.—A discussion was opened by Mr. W. Watson Cheyne on the Diagnosis and Treatment of Fractures in the Neighbourhood of Joints; he advocated reducing such fractures under an x ray screen. Skiagrams must also be taken so that the position of the bones after reduction could be known. If the bones were not in good position a second attempt must be made to reduce the fracture, and if after this the displacement had not been remedied, unless there was some marked contra-indication, open operation must be resorted to, and he advised the employment of screws or pegs.—Mr. Edmund Owen insisted on the importance of an anæsthetic being given for the purpose of arriving at a diagnosis in cases where there was any doubt or difficulty.—Mr. A. Pearce Gould contended that in the diagnosis of a fracture near a joint the best time for making a correct diagnosis was immediately after the injury.—Mr. W. Arbuthnot Lane described the different operative procedures necessary in fractures near joints and produced numerous skiagrams illustrating many kinds of such fractures showing the position of the bones before and after operation, the bones being kept in place by wires, screws, plates, and staples or combinations of these.—Mr. Robert Jones of Liverpool described his method of treating fractures of the ankle-joint in children.—Mr. Watson Cheyne replied after some remarks from Mr. W. H. Olayton-Greene and Mr. T. Crisp English.

Reviews and Notices of Books.

The Puerperium, or the Management of the Lying-in Woman and New-born Infant. By O. NEPEAN LONGRIDGE, M.D., Ch.B. Vict., F.R.O.S. Eng., M.R.C.P. Lond. London: Adlard and Son. 1906. Pp. 272. Price 5s.

As the author remarks in his preface, the details of the treatment of the puerperal period are often inadequately taught in a general hospital and insufficiently described in the ordinary text-book on midwifery. His little work therefore supplies a want and will, we are sure, be welcomed by those students and midwives for whom it is intended. It

has the further advantage that it embodies the teaching current in these matters at Queen Charlotte's Hospital. In the section on post-partum hæmorrhage the author states that he has determined the coagulation time of the blood in ten women a few hours after they were delivered and found that there was no appreciable shortening of this period. This result is in accordance with the most recent investigations on the changes to be found in the blood during pregnancy. On p. 12 we find the statement that chloroform up to a certain point predisposes to uterine inertia. This is not a very exact statement. Pinard and others have shown that chloroform tends to interfere with the retraction of the uterus rather than with the contractions but it must always be borne in mind that the condition for which the chloroform is given really may be the cause of the inertia. In the description of the third stage of labour Dr. Longridge is in error in saying that the swelling above the pubes is due to the placenta lying in the vagina; it is due to the placenta lying partly in the lower uterine segment and partly in the upper part of the vagina, as can be readily ascertained by making a vaginal examination at this stage of labour.

In discussing the question whether the hand should be introduced into the uterus to extract a piece of membrane attention should have been drawn to the fact that while a piece of chorion readily breaks up and comes away this is not so with pieces of amnion which should always be removed. The statement that lacerations of the perineum occur more frequently in forceps deliveries we are not inclined to agree with: it is not our experience, nor was it that of a predecessor of Dr. Longridge, Dr. George Porter Mathew, who in a pamphlet entitled "Clinical Observations on 2000 Cases of Labour" stated that in his practice at Queen Charlotte's and other hospitals by the use of axis-traction forceps he had delivered 21 primipara without a single tear of the perineum. We agree with him in thinking that the use of axis-traction forceps more often prevents a tear than produces one. In the treatment of complete tears of the perineum no mention is made of the method of postponing the operation if necessary so as to have the advantage of proper assistance and a good light; such postponement can last for 12 hours without any fear of interfering with the primary union of the parts. We much doubt the wisdom of recommending catgut for the rectal stitches, even if introduced in the manner described.

In stating that the blood pressure shows a decided fall after delivery Dr. Longridge should have added that this fall only lasts for the first four or five days of the puerperium. A word of caution is necessary in advising the administration of urotropine in cases of cystitis. A dose as large as ten grains three times a day is often accompanied by the appearance of albumin in the urine; from five to seven grains is quite a large enough dose. We entirely disagree with the advice that a ring pessary should be put in if on the final examination on the patient getting out of bed the uterus is found displaced. The introduction of a ring pessary into the vagina before involution is complete is, in our opinion, very bad practice and almost certainly produces sub-involution of that canal. If a pessary is put in at all it should certainly be a Hodge but even this, we think, is better avoided. We are surprised to find that in the practice of the hospital to which this book mainly refers vaseline is immersed in 1 in 1000 perchloride of mercury is used as a lubricant and it is apparently not the practice to wear gloves when the hand is introduced into the uterus. The book is good so far as details of treatment and the description of the simpler affections of the puerperium are concerned but the account of puerperal parametritis is poor and should either be left out or entirely rewritten in another edition. From the description given it would be impossible for the student to recognise a typical case with a swelling above Poupart's

ligament, and it is certainly not true to say that from the practical clinical aspect pelvic peritonitis and cellulitis should be described together, if the author is really alluding to a typical case of the latter disease.

As a guide to the treatment of the normal puerperium the book is a good one but when the author discusses other matters he is not so trustworthy.

Medical Diagnosis: A Manual of Clinical Methods for Practitioners and Students. By J. J. GRAHAM BROWN, M.D. Edin., F.R.C.P. Edin., F.R.S. Edin., Assistant Physician, Royal Infirmary of Edinburgh; and W. T. RITCHIE, M.D. Edin., F.R.C.P. Edin., F.R.S. Edin., Clinical Assistant Pathologist, Royal Infirmary of Edinburgh. Fifth edition, greatly enlarged and revised to date, with 200 illustrations and eight full-page plates. Edinburgh and London: William Green and Sons. 1906. Pp. xvi-508. Price 8s. net.

THE importance of a knowledge of clinical methods is demonstrated by the increasing attention devoted to them in the medical curriculum, and by the appearance of numerous text-books and manuals dealing with what is frequently denoted as clinical research. The important advances which have within recent years been made in the methods for the microscopical examination of the blood, for the study of the various body fluids and excreta, and for their chemical investigation render it essential that any book on the subject shall be kept approximately up to date. In the book before us, which has now reached its fifth edition, an intelligible and practical account of many of the recent methods of investigation has been included, which justifies the authors' claims to have brought the book in line with present knowledge.

After an introductory chapter on the general aspect, condition, and circumstances of a patient, the various systems of the body are separately considered. In connexion with each the ordinary routine investigation is given, including that of the ordinary symptoms and subjective phenomena. The various physical signs are then described and their demonstration by the methods of inspection, palpation, percussion, auscultation, and mensuration is indicated in so far as they are applicable. As a rule the descriptions of these physical signs are clear and are written in such terms as easily to be understood; in each case the indications are given, their diagnostic value is stated, and their limitations or fallacies are exposed. Further, in each section any special methods employed are described, such as instrumental or graphic records and the chemical and bacteriological investigation of fluids or excreta associated with that system. Among these special chapters we may mention that on the examination of the gastric contents in which the methods employed for the study of test meals are given and the value of the information derived therefrom is discussed, while the means for the investigation of vomit and faeces are added.

The chapter on the investigation of the blood is worthy of special commendation, for within a comparatively short compass a great deal of valuable practical information is compressed; it is, moreover, liberally illustrated both with diagrams and coloured plates. The numerous varieties of normal and abnormal blood corpuscles are very clearly described and portrayed. The descriptions of methods of preparing and staining films for differential blood counts and for demonstrating parasites are succinct and practical. A short illustrated paragraph is added on the cryoscopy of the blood and an account is given of the method of working with Zikel's cryoscope which is sufficient to enable that instrument to be used. The account of the spectroscopic investigation of some of the derivatives of the blood pigment might with advantage have been a little more detailed in view of their importance.

In the section dealing with the circulatory system the description given of graphic clinical methods is good and we are glad to see that the excellent work of Dr. J. Mackenzie

of Burnley is recognised and his apparatus described. The diagrams of pulse tracings and of the various forms of irregularity of the pulse are good and the phenomena of heart block and extra systole are discussed.

In the investigation of the respiratory system an apparatus, the perigraph, devised by one of the authors, appears to give more accurately information usually obtained by the cyrtometer. The routine methods of urinary investigation are described in detail and the various crystals, deposits, and parasites found in the urine are figured.

In connexion with the nervous system, the elucidation of its various functions and their derangement is worked out in detail and much of the newer work on these subjects is incorporated, including Dr. H. Head's views on deep, protopathic, and epicritic sensibility. In the chapter dealing with the visual functions the space devoted to a consideration of colour vision is hardly commensurate with its importance. The last two chapters are devoted to clinical bacteriology and cyto-diagnosis and are among the best in the book. The former includes accounts of the more common pathogenic organisms and their separation from the body and also of the investigation of the agglutinating and opsonic reactions. The chapter on cyto-diagnosis affords a useful summary of the more important facts at present known.

The book as a whole is eminently practical and one which we can cordially recommend to the student in the wards and to the practitioner who wishes to keep abreast of the modern advances in diagnostic methods.

Prevalent Diseases of the Eye: a Reference Handbook, especially adapted to the Needs of the General Practitioner and the Medical Student. By SAMUEL THEOBALD, M.D., Clinical Professor of Ophthalmology and Otolaryngology in the Johns Hopkins University, &c. With 219 illustrations and ten coloured plates. London and Philadelphia: W. B. Saunders Company. 1906. Pp. 551. Price 19s. net.

Professor Theobald does not consider that the ordinary treatises upon diseases of the eye, though ostensibly written for the general practitioner and the medical student, are in reality suited to their needs. He thinks that a treatise designed to meet the requirements of general practitioners must take into account the fact that they are, as a rule, unskilled in the use of the ophthalmoscope and possess neither the experience nor the necessary paraphernalia to make trustworthy tests of refractive errors, of muscular anomalies, or of visual fields. We find ourselves largely in agreement with the remarks contained in the author's preface. We think that the average medical student should confine himself to the study and diagnosis of the commoner ailments affecting the eyes, paying special attention to the grouping of cases into those which he may consider himself justified in treating unaided and those which he should hand over to the ophthalmic surgeon. Amongst the latter we include the correction of errors of refraction and muscular balance which cannot be mastered by the average medical student in the time and with the opportunities at his disposal. We do not think, however, that any one book can be devised which will satisfactorily meet the requirements of the medical student and of the practitioner whose education in ophthalmology has been neglected. Whilst the medical student should not consider himself qualified to correct refractions or to do ophthalmic operations, he ought to possess a sound knowledge of the principles which guide the skilled ophthalmologist and of the technique which he employs. A book written for the general practitioner who is unskilled in the use of the ophthalmoscope must of necessity be an unsatisfactory production both to the author and to the reader.

In so far as Professor Theobald has carried out his scheme he has produced an emasculated text-book but fortunately for the value of his work he has not adhered very strictly to

the principles laid down in his preface. Hence we find that more than a quarter of the text is devoted to diseases of the choroid, retina, and optic nerve, with their ophthalmoscopic features, to anomalies of refraction and accommodation, and to muscular anomalies. The work is, indeed, a fairly satisfactory text-book of diseases of the eye, marred, rather than improved, by the limitations set upon himself by the author. Detailed investigation of the material reveals many statements with which it is impossible to agree but a large proportion of these are the expression of the author's individual opinion. This is notably the case in dealing with lacrymal obstruction, where the use of giant probes is strongly advocated. It is not to be expected that a pioneer in this mode of treatment would forego advocating his method, though to those who are accustomed to other methods he condemns it by stating that "the treatment frequently extends over a period of eight or ten months, but the active treatment, involving the frequent probings, is comprised within as many weeks."

Without desiring to detract from the general utility of the book we may point out a few statements which appear to us to be inaccurate or to require modification. Stress is laid upon the importance of distinguishing phlyctenular from catarrhal conjunctivitis, because the treatment for the latter is deleterious in the former. Considering that the two conditions are combined in the great majority of hospital cases the advice loses its point; moreover, we do not agree that atropine is indicated in phlyctenular conjunctivitis when the cornea is not involved. We do not agree that care should be taken not to perforate the cornea in canterising for conical cornea; in our experience the operation fails unless the cornea is perforated, though, of course, the dangers of the treatment are much increased. "Serous" iritis is said to be rarely a binocular affection, and sympathetic ophthalmia an occasional result of neglected iritis. In discussing the maturity of senile cataract no mention is made of the iris shadow; the advice is given to operate on mature unilateral cataract, and Förster's method of artificial maturation is advocated.

The author's knowledge of the pathology of ocular diseases appears to be faulty. He wisely avoids making more reference to this aspect of the subject than is absolutely necessary. As is often the case in such circumstances, he shows a marked penchant for doubtful theories. Insufficiency of the internal rectus is regarded as an important factor in the causation of pterygium. Iritis, cyclitis, and so on, are attributed to "an influence transmitted through sympathetic or 'trophic' nerves, which is frequently reflex in character and is probably dependent upon structural changes in grey nerve matter, either in the cerebral ganglia themselves or in the ganglia connected with the fifth nerve, or both," undue importance being attached to hypothetical lesions of the ophthalmic ganglion. Detachment of the retina, which is one of the most obscure problems of pathology, is regarded as requiring no "elaborate and far-fetched theories" for its explanation. Errors of refraction and muscular anomalies are looked upon as important factors in the etiology of cataract, glaucoma, choroido-retinitis, and so on.

The book is well printed. The illustrations are numerous; they are mostly borrowed from well-known sources and many lose much by the absence of the colours used in the originals. There is an excellent index.

Sanitary Engineering with Respect to Water-Supply and Sewage Disposal. By LEVESON FRANÇOIS VERNON-HARCOURT, M.A., M.Inst.C.E. Longmans' Civil Engineering Series. 1907. Price 14s. net.

THIS is not only a useful book of reference for students, but it is written in a form suitable for such non-technical readers as are interested in the subjects dealt with. The author gives a rapid though well-digested survey of the

whole question. From the collection of the water at its original source it is followed through the several stages of storage, transit, filtration, and distribution, and afterwards during its removal, subsequent purification, and disposal—in fact, it is only lost sight of during the brief period of its passage through human or other organisms. The value of the book is increased by the full index and abundant illustrations. Certainly a good deal of detail might have been added which would have increased its value as a text-book, at the cost, however, of rendering it less acceptable to many readers.

The first section on water-supply occupies the major part of the volume; the several sources and the methods employed to utilise them are treated of much in the usual order—viz., rainfall, springs, deep and shallow wells, mountain streams, rivers and lakes. There is a chapter on well-boring, illustrating the tools used for the purpose, which is interesting. Detailed descriptions are given of most of the large engineering works for impounding water in various parts of the world and the known defects and advantages of their construction are discussed. The descriptions given of such works existing in our own country, together with the geological sections and maps of rainfall, should prove useful to very many engaged in local sanitary work. One point very often lost sight of by authors of similar works is the possible pollution of long mains by the water passing through them. This is dealt with in the case of the 18½ miles of main from Lake Vyrnwy to Oswestry for the supply of Liverpool.

In reading this book we are struck by the extreme simplicity in conception of many of these stupendous engineering works. Mr. Vernon-Harcourt tells us in the preface that the compilation of the book occupied his attention over a period of five years. This can well be understood; only those who have attempted a similar task, even in a small way, can appreciate the amount of trouble attending the production of such a work and in avoiding innumerable side issues in order to restrain it within moderate dimensions. Space forbids us to follow in detail the description of the various fittings, reservoirs, filter beds, mains, and meters.

In the section devoted to house fittings brevity is the predominant feature but in the short space allotted to them we notice that the following points are not in accordance with the present practice. The ventilating pipe to the trap in illustration of the sink (Fig. 204) should not have been omitted, neither is it desirable to have the gully fixed, as is shown, so close to the wall. The form of the Dip grease trap (Fig. 206) is a revival of one long since discarded owing to the accumulation of grease in the corners which renders it very objectionable. Again, the addition of a syphon trap on the outlet, in the absence of any air inlet between the two traps, would soon lead to trouble. The long neck to the rain-water gully at the upper end of the drain (Fig. 210) is also not a thing to imitate. A quicker fall than is shown at Fig. 212 to the bottom channel of the intercepting chamber greatly helps to clear the syphon trap and to prevent stoppage. The water seal as shown to the syphon is very insufficient. With regard to refuse destructors, though these have proved a boon to our big cities and large towns, it may be open to question whether they are not unnecessary and wasteful in rural districts. In describing certain sewers in Paris, the author says "they are sufficiently commodious to accommodate gas and water pipes suspended on side brackets near the top, or in case of large water conduits on slender columns." This is indeed making extremes meet; a little less of the *entente cordiale* in the matter of sewage and drinking water seems desirable. The frequent repairs and alterations necessary to these pipes cannot be carried out with the minimum risk of contamination possible amidst more favourable surroundings. The

description of the outfall sewers at Barking and Crossness into which the sewage has to be lifted by pumping suggests the awful condition into which London would be thrown in the event of a hostile fleet ever succeeding in entering the Thames and demolishing the pumping stations. The descriptions of the various systems of sewage disposal are on the well-known lines familiar to most of our readers.

The book is, in the main, an excellent one considered as an epitome of some of the best that has been written on a large and difficult subject but the individuality of the author is rather lost in the editor; with a few exceptions we look in vain for new ideas or for practice discussed from a fresh standpoint. We can, however, strongly recommend the book to medical officers of health as placing the whole subject before them in a concise form.

Nasal Sinus Surgery, with Operations on Nose and Throat. By BEAMAN DOUGLASS, M.D., Professor of Diseases of the Nose and Throat in the New York Post-Graduate Medical School and Hospital. Illustrated with 68 full-page half-tone and coloured plates, including nearly 100 figures. Philadelphia: F. A. Davis Company, 1906. Royal octavo, pp. 256. Bound in extra cloth, price \$2.50 net.

THE first chapter of this work is devoted to a general anatomical review of the nose. The second chapter is devoted largely to the surgery of the frontal sinus. The operations on the frontal sinus itself are very briefly described and would be hardly sufficiently explicit for the novice. The third chapter deals with the ethmoidal sinuses. In this chapter the excellent work of Laek obtains no recognition and we may recommend Dr. Douglass to include a description of it in his next edition. Descriptions of the operations on the antrum follow next and here, again, we may remark upon the absence of any description of the more complete operative procedures on its inner wall. A description of the sphenoidal sinus and its surgery completes the work on the sinuses. The sixth chapter deals with deflections of the nasal septum, operations for nasal deformities, and the injection of paraffin. We note that the submucous resection, which is described in what might be termed a casual manner, gives little indication of the difficulties so frequently met with, nor any description of the necessary instruments, particularly Barranger's resection knife. In the description of the operative methods any reference to the more recent methods of cold paraffin injection is omitted. We are informed on page 224 that in England the operation of removal of the posterior ends of the turbinates is performed by means of a spokeshave instrument or a sharp ringed curette and that this method is mentioned only to be condemned. We quite agree with the condemnation but are glad to say that, to the best of our knowledge, such an operation is not performed in England. The final chapter briefly describes laryngeal and tracheal operations.

LIBRARY TABLE.

A Health Reader. By O. E. SHILLY, M.D. Cantab., Consulting Medical Officer, Halleybury College, and E. STENHOUSE, B.Sc., Associate of the Royal College of Science. Book I. London: Macmillan and Co., 1906. Pp. 160. Price 1s.—From this little book young people may learn the chief facts about the human body and the uses of the different parts of it. As the authors write, much of the pain and trouble in the world could be prevented if people would only learn how to treat their bodies properly. The book is divided into 30 lessons; the subject matter of each is well arranged and simply expressed. The final chapter deals with "Good and Bad Habits." It is just as easy to form good habits as it is to form bad ones. The collaborators not only draw attention to bad habits which harm or annoy others

but to the kind of bad habit which does no one else any harm but still prevents a child from becoming strong and healthy. Habits of this kind are, smoking, breathing through the open mouth, stooping over books or work, and slouching when walking or standing. The authors state that "carelessness in talking leads to the shameful habit of telling lies, and it weakens the brain." The little book, which is illustrated, is what it pretends to be and can, only do good to those who read it.

Cancer: Its Treatment by Modern Methods. Being the Bradshaw Lecture for 1906. By EDMUND OWEN, Senior Vice-President of the Royal College of Surgeons of England. London: Baillière, Tindall, and Cox, 1907. Pp. 31. Price 1s.—Mr. Owen has published this lecture because it puts the case in a straightforward way, which is much needed at present. He reminds us that the treatment of cancer "is unfortunately not the same thing as cure, and that the most effectual treatment for cancer, no matter how small it may be, is still removal by the knife." We published the lecture in full so that our readers know Mr. Owen's views, which are practical but not final. One fact of importance obtained in the research laboratories in the course of inoculation experiments upon mice is that, every now and then, a mouse which has been infected with cancer triumphs over the disease and at last gets entirely free from it. The same thing sometimes occurs in the human subject but too rarely to form a ground for expecting such a result in any case or group of cases. Mr. Owen feels sure that the ultimate victory over cancer will not be solely by the knife. But whatever the great curative method may eventually prove to be the knife will, in all probability, still be needed for the removal of the primary lesion. The lecture is most interesting and will, no doubt, be widely read.

Die Topographie des Lymphgefässapparates des Kopfes und des Halses in ihrer Bedeutung für die Chirurgie. (The Topography of the Lymphatic Apparatus of the Head and Neck in its Relation to Surgery.) By Dr. AUGUST MOST, Breslau. With 11 plates. Berlin: August Hirschwald, 1906. Pp. 133. Price 9 marks.—Dr. Most's book forms a useful addition to the literature of the lymphatic system in man. The recent publication of several works on this subject affords some indication of the increasing attention which is being paid to this department of human anatomy, chiefly owing to the demands of surgery. Of the more recent works, Mr. Cecil H. Leaf's translation of Professor Poirier's masterly treatise is perhaps the best known to English readers. So far as pure anatomy is concerned, Dr. Most follows the usual lines, describing first the general arrangement of the lymph glands of the head and neck, and in succeeding chapters considering the lymphatics of the integuments and superficial structures, of the salivary glands, and of the various mucous surfaces. The clinical and operative bearings of the subject receive a due share of the author's attention and in this respect the book ranks rather with applied than with purely descriptive anatomy. There are 11 plates as well as two figures in the text. The lymphatic vessels are depicted as they appear in young subjects and the illustrations convey a clear idea of the course of the lymphatics from the eyelids, lips, nasal fossae, auricles, and other parts.

The Proceedings of the Anatomical and Anthropological Society of the University of Aberdeen for 1904-05. Aberdeen University Press, Limited.—These Proceedings are full of interest. From a purely anatomical point of view a record of an investigation of the Mode of Development of the Lower Jaw in Man will well repay perusal. Dr. Alexander Low, who carried out the research, concludes that each half of the mandible is developed in membrane as a single skeletal element—the dentary and

that the so-called splenial element is simply an extension of this. He also states that Meckel's cartilage becomes ossified and incorporated only with that part of the lower jaw which is below and inside the mesial and lateral incisor teeth. Accessory cartilaginous nuclei appear for the condylar and coronoid processes, but not, in man, for the angle. Professor R. W. Reid, the President of the society, contributes some Notes on a Mesial Sagittal Section of a Female Subject. In the section the spinal cord is compressed antero-posteriorly and laterally by a mass of gliomatous tissue which extends throughout the whole length of the spinal canal, is attached to the pia mater, and is invested by the dura mater. Professor Reid suggests that this may be an attempt at duplication of the cord but remarks that it also resembles certain cases which are described as diffuse sarcoma of the pia mater. The Proceedings contain a large amount of anthropological material. Papers are contributed by Mr. D. Horn, B.A., of Queensland on the People of the New Hebrides; by Mr. F. S. Maxwell of Sierra Leone on Hausaland and its Inhabitants; by Mr. George Moir, M.R.C.V.S., on the Natives of the Malay Peninsula; and by Captain A. W. Cook Young, I.M.S., on Tibet. In an interesting description of Four Short Clists from Aberdeenshire Dr. Low remarks that they furnish evidence of burial by inhumation as well as by incineration, the former being the earlier practice. He also corroborates Dr. T. H. Bryce's view that the beaker class of sepulchral urn, which is the oldest Bronze Age ceramic, is associated with a specific cranial type. We commend a paper by Mr. F. G. Parsons on the Anatomical Education of the Medical Student to the attention of all teachers of anatomy.

New Inventions.

MOUSTACHE CLIPS FOR LARYNGOSCOPY.

A PAIR of small spring forceps, such as are sold for the purpose of raising the ends of the moustache, are very useful for temporarily keeping up an overhanging moustache during an examination of the pharynx, larynx, or naso-pharynx. They must be applied horizontally, just on either side of the median line, with the fluted blade below and the handles

directed outwards as shown in the accompanying figure. They may be obtained of Messrs. Mayer and Metzger, 71, Great Portland-street, London, W. E. CRESSWELL BABER.

IMPROVED MOUTH GAG.

WHILE doing operations on the mouth I have been struck by the inadequacy of the gags in use. All that I have seen are liable to slip into the mouth, particularly if there are teeth in the upper jaw and corresponding vacancies in the lower and *vice versa*. To obviate this I have had a gag made which, as shown in the illustration, has two wide tooth-plates which fit firmly over either teeth or gum, as the case

may be, and when fixed in position by the screw it is, as far as my experience goes, impossible for it to slip into the mouth or even to move. The gag, which I have been using for nearly 18 months, was made for me by Messrs. White and Wright, 93, Renshaw-street, Liverpool. The plates measure $1\frac{1}{4}$ inches by $\frac{3}{4}$ inch and are covered with rubber.

H. LYLE, M.R.C.S. Eng.,

Senior Surgeon to the Cancer and Skin Hospital,
Liverpool.

THE USE OF ALCOHOLIC BEVERAGES.

WE have received the following document for publication in THE LANCET. As an expression of scientific opinion it deserves to be considered carefully by medical practitioners. The signatories are well-known members of the profession, and the importance of the questions involved, alike from the medical and the social point of view, can hardly be over-estimated.

"In view of the statements frequently made as to present medical opinion regarding alcohol and alcoholic beverages, we, the undersigned, think it desirable to issue the following short statement on the subject—a statement which we believe represents the opinions of the leading clinical teachers as well as of the great majority of medical practitioners.

"Recognising that, in prescribing alcohol, the requirements of the individual must be the governing rule, we are convinced of the correctness of the opinion so long and generally held, that in disease alcohol is a rapid and trustworthy restorative. In many cases it may be truly described as life-preserving, owing to its power to sustain cardiac and nervous energy, while protecting the wasting nitrogenous tissues.

"As an article of diet we hold that the universal belief of civilised mankind that the moderate use of alcoholic beverages is, for adults, usually beneficial, is amply justified.

"We deplore the evils arising from the abuse of alcoholic beverages. But it is obvious that there is nothing, however beneficial, which does not by excess become injurious."

we have no data for comparison, no means of correctly estimating either the strength or the weakness of former generations. The evidence, in so far as it exists, is not wholly unfavourable, for the operation of the laws collectively known as the Factory Acts has tended greatly to improve the conditions of work and of life among large classes of operatives, more especially with regard to children. An important factor in the agitation by which the Factory Acts were produced was the publication, in 1840, of Mrs. TROLLOPE's novel, "Michael Armstrong, or the Factory Boy," which was abundantly illustrated by pictures showing the condition of factory "apprentices" at the time, pictures for which it would be difficult or impossible to find any living parallels in our own day, but which, when they appeared, were not accused of inaccuracy or exaggeration. It must be remembered, on the other hand, that the manufacturing population of that time bore a much smaller proportion to the total population than at present and that comparatively few of the "apprentices" would be likely to survive to maturity. Their condition, moreover, was flagrant and unmistakeable, whereas what we have now to dread is an insidious and general decline of strength and activity, rather than the crushing out of a small section of workers by evils of an overwhelming character. In order duly to protect ourselves and our descendants against possible and by no means problematical evils, we want to know what is the average physical standard of the country at successive years of life, and how far this standard is departed from in different localities, among different classes, and by the children of persons engaged in different occupations. We want to know how far it is departed from in the numerous rural districts intended by nature to be healthy but in which local "authorities" ordain that the causes of disease shall prevail unchecked. We want to compare the children of ten years old, in places of excessive infantile mortality, with those of the same age in places where the infantile mortality is kept within due bounds, in order that we may know to what extent the conditions which destroy infant life serve also to impair the health of the survivors. These questions are not only important, as admitted by the Prime Minister, but they are vital. Upon the accuracy of the replies given to them may depend the future of the Empire and, when compared to them, politicians and party leaders are of no more account than the dry leaves of autumn. When the strong man armed keepeth his house his goods are at peace; and strength is the only secure foundation of dominion.

The Clinical Significance of Iodophilia.

A PATHOLOGICAL and clinical study of the iodine reaction of the leucocytes affords the basis of an interesting and important paper by Dr. JOHN O. DA COSTA, jun., published in the *Proceedings of the Pathological Society of Philadelphia*, N.S., Vol. IX., p. 113, 1906. Since EHRLICH described the reaction in 1883 numerous observations have been made, yielding results which in many of the details are so conflicting as to render the test one rather of interest to the

scientific hematologist than of value to the clinician. Dr. DA COSTA's paper is especially noteworthy and important, not only from the fact that he has examined and correlated the work of previous investigators, but also from the careful critical study which he has made of his own results in the light of their observations. His summary of the general results of previous workers is "that the iodine reaction occurs with great constancy in conditions of toxæmia both bacterial and non-bacterial; that it signifies a lowered vitality of the iodophilous cells, and that its exact nature is not definitely understood. Of bacterial toxæmias productive of iodophilia, such conditions as pyogenic abscess, general sepsis, and many of the specific febrile infections are the underlying factors; while iodophilia, excited by non-bacterial or chemical toxæmia, may develop, for example, in diabetes mellitus, in leukaemia, in dyspnoea, in acetanilid poisoning, after ether narcosis, and perhaps in high-grade anæmias."

The nature of the iodophilous reaction may be briefly stated to be a peculiar susceptibility of the protoplasm of the leucocytes, notably the polymorphonuclear variety in certain abnormal conditions, to the action of iodine applied to the dried film which stains it a variable shade of brown, whereas the protoplasm of normal leucocytes in dried films assumes a pale lemon-yellow tint only. It is important, however, to note that a fresh moist film of normal blood exposed to iodine vapour before drying occurs shows the brown staining in a manner precisely similar to that in dried films of abnormal blood, which as suggested by WOLFF indicates that the iodophilous substance, presumably glycogen, is normally present in the circulating leucocytes of healthy blood, but in the drying of the film it is altered so as to be no longer demonstrable by iodine. Two theories have been propounded to explain these facts, the first that of WOLFF, which supposes that in the iodophilous leucocytes of disease the glycogen, normally so soluble that it is unaffected by iodine, has become abnormally insoluble by the action of some toxic influence and hence retains the power of staining with iodine in the dried film. The second theory, brought forward by SOROCHOWITZ, explains the reaction by supposing that normally the glycogen is rapidly converted into glucose by a ferment the action of which is hindered in toxic conditions, so that an accumulation of glycogen occurs in the protoplasm.

Dr. DA COSTA's observations were made upon 100 patients suffering from various acute infections and chronic disorders by examining films for the iodine reaction, while in 50 of the cases hæmoglobin estimations, and blood counts, both absolute and differential, were also made. In 50 of the cases giving positive reactions the percentage of iodophiles and of the different cells showing the reaction were calculated. Similar observations on 20 healthy subjects for purposes of control gave uniformly negative results. In the 100 cases of disease a positive reaction was obtained in 54, in all of which it was possible to refer the cause to pyogenic sepsis or chemical toxæmia. 26 of the patients examined were suffering from enteric fever—of these nine showed iodophilia; most of these were cases of severe infection, complicated in two instances by pneumonia and in others by local peritonitis, by free intestinal hæmorrhage, and by general septicæmia. The reaction cannot be said to have

any specific diagnostic value in this disease, since it may obviously occur under many diverse conditions. In 80 cases of purulent and septic conditions, such as appendicular abscess and gangrene, pelvic abscess, empyema of the gall-bladder, hepatic abscess, purulent peritonitis, and general septicæmia, the reaction was positive in all, its intensity apparently depending rather upon the virulence of the pathogenic organism than upon its identity or upon the extent of the associated suppuration. Iodophilia was found in two cases of catarrhal inflammation of the appendix, as well as in all the cases of purulent and gangrenous appendicitis, so that it does not serve to distinguish between the catarrhal and suppurative forms of the disease. In croupous pneumonia the seven cases tested all gave positive results during the height of the febrile period of the disease, and in no other disease, not even in grave streptococcus septicæmia, was so marked a reaction observed. After the crisis the iodophilia rapidly begins to disappear and does so completely within 48 hours in uncomplicated cases but persists when delayed resolution, pulmonary abscess, or empyema follows the pneumonia. Four cases of gonorrhœal arthritis gave a positive reaction to the iodine test and the reaction was observed in cases of acute pneumonic phthisis, carcinoma, pernicious anæmia, myelogenous leucæmia, diabetes mellitus, and amyloid liver, while negative results were obtained in rheumatic fever, endometritis, cholelithiasis, biliary cirrhosis, malarial splenomegaly, ovarian cyst, rickets, and acetanilid poisoning. From a careful critical and statistical analysis of his results Dr. DA COSTA derives the following general conclusions. In the dry blood film intracellular iodophilia indicates a form of leucocyte degeneration of toxic origin, due presumably to an abnormal affinity of the cell glycogen for iodine, the same reaction in the wet fresh blood being physiological. Extracellular masses in the plasma staining with iodine have apparently no pathological significance. The toxic factor in the production of the reaction may be readily demonstrable, as in pyogenic septicæmia and pneumonia, or it may be indefinite, as in pernicious anæmia and in cachectic states. The reaction is found to be restricted to the cytoplasm of the leucocytes, never affecting the nuclei. In 93 per cent. of all reactions the polymorphonuclear neutrophil leucocytes are implicated; in about 20 per cent. other cells, notably the lymphocytes and less commonly the myelocytes, while it is only in exceptional instances that iodophilous eosinophiles are noted. The number of cells staining with iodine is found to correspond roughly with the colour intensity of the reaction, 50 per cent. or more of iodophiles being found in a decided, and about 25 per cent. in a feeble, reaction. Iodophilia apparently shows no definite relation to leucocytosis, to anæmia, or to pyrexia. Dr. DA COSTA concludes that from a clinical standpoint iodophilia is often a helpful, though in no circumstances a diagnostic, sign, and specifically states that in differentiating various clinical entities extreme caution must be exercised in accepting it as a criterion, although he has found it of value as corroborative evidence in distinguishing both gonorrhœal arthritis and osteomyelitis from rheumatic fever, pure tuberculosis from tuberculosis with secondary pyogenic invasion, and amyloid liver from fatty cirrhotic liver.

The Workmen's Compensation Act, 1906.¹

IN THE LANCET of Jan. 28th we suggested that as the cost of a copy of the new Workmen's Compensation Act is but 4d. many of those most concerned would before long purchase and make themselves acquainted with its provisions. They may consider it with or without the assistance of a legal text-book and they will find their attention directed to the points of interest to medical men in the articles and letters which we have published. The questions which are likely to arise, but which are not provided for conclusively under the Act, can to some extent be predicted; but special prescience is hardly required in order to foretell that others will present themselves from time to time which have not been anticipated and with regard to which the interpretation of the law will be found to be doubtful. We note that the insurance companies are making full provision against this contingency for such as like to avail themselves of policies framed against all risks, and that those willing to incur the necessary cost can without any very large outlay protect themselves against the new liabilities now imposed upon them, as well as against those which existed before but which so seldom made themselves felt that insurance was not usually deemed necessary. Those possible instances also are not forgotten where the servant may become affected by a disablement not due to a cause for which his master or anyone else is liable, but for which a prudent and kind-hearted employer will often wish to provide if it is made easy for him to do so. The question of insurance is one for the serious consideration of all, but for medical men it is especially so because they are employers of persons whose risks are to some extent peculiar owing to the circumstances of the medical profession, and because also they are employers of persons whose work, dangerous or otherwise, like that of their masters, is carried on constantly without the limitation of regular hours of labour or of any fixed place of employment. The servant of the medical man, for instance, employed in keeping clean his surgery or his dispensary, is liable to accidents which may be rare but which differ from those occurring in other domestic service. The coachman of the lay employer has his hours of work which in some families imply night work, but which, as a rule, are of more or less fixed duration. The coachman of the medical man, particularly when his practice lies in a country district, never knows when his day's work will begin or end, and it takes him along rougher roads than that of the man who drives his master or his mistress merely for their pleasure.

We have before us a cheap but serviceable explanatory guide to the new Act, published by the *Daily Chronicle* at 1d., and we note some practical advice given on its last page in relation to insurance, where it recommends that care should be taken to see that the policy provides against every contingency possible in the master's service. It calls particular attention to extra servants casually employed and to the possible requirement in a policy of notice to the office of such

¹ See also THE LANCET, Oct. 15th, 1906, p. 1012; Nov. 10th, 1906, p. 1336; Dec. 8th, 1906, p. 1612; Jan. 12th, 1907, p. 112; Jan. 25th, 1907, p. 246.

employment before the insurance company will hold itself responsible. It also points out that the provisions of the policy as to change of servants are to be considered with care. We need only mention the locum-tenent, the assistant, and the nurse in order to show that the medical man is peculiarly liable to have in his employment persons with regard to whom a liability may possibly arise and may be disputed, whose employment may be temporary only, and whose salaries forming the basis upon which the employer's liability is calculated, are above the usual emoluments of the ordinary workman or domestic servant. It is with regard to the nurse again that questions may arise as to whether her employment is "casual," and also as to who may be her employer, and the same point will be mooted as to humbler workers whom the medical man, according to the exigencies of his profession and apart from his position as an ordinary citizen, may call in to perform various services. The accidents against which provision is to be made by insurance have hitherto not attracted much attention and are regarded as of infrequent occurrence, but we must wait until the privileges of the Act have been enjoyed for a few years before we are able to appreciate the effect of the compensation provided in increasing the occasions for seeking it. The schedule of the Act which lays down the scale and conditions of compensation contains more that is of special interest to the medical man in the exercise of his profession than does the body of the statute. We are already familiar with the claims of the workman against his master, all medical men having been brought into contact with such cases, but under the new Act every general practitioner will find himself now and again summoned either by the employer or the employed in the large class of domestic servants. Here accidents as a rule will not be serious and the medical man may frequently be reminded that "if the incapacity lasts less than two weeks no compensation shall be payable in respect of the first week," and we can foresee that where the period of incapacity has to be fixed according to the medical man's judgment he will often have a difficult task.

In various ways the medical profession finds itself expected to perform semi-judicial rather than healing functions under the new law, and we are confident that it will not fail to do so with honourable impartiality. The occasions may increase on which the medical man will be tempted "to take a side" involuntarily when forming and declaring his opinion, but the augmented powers of medical referees will bring disputed medical questions under the consideration of those qualified by their training to decide them. An instance of the medical referee's powers is contained in the fifteenth paragraph of the schedule referred to, which provides that "where no agreement can be come to between the employer and the workman as to whether or to what extent the incapacity of the workman is due to the accident, the provisions of this paragraph shall, subject to any regulations made by the Secretary of State, apply as if the question were a question as to the condition of the workman;" that is to say, this point, which in ordinary actions is regarded as one well within the competence of a judge or of a jury of laymen, is to be submitted to a medical referee whose certificate shall be conclusive upon the matter.

It is to be hoped that before July 1st, when the Act will come into force, and when, so far as medical referees are concerned, it will apply to accidents occurring before that date, the rules of the Home Office for regulating the proceedings of medical referees will have been long enough before the medical profession to be studied carefully and for attention to be called to any points in which, as may easily occur upon such occasions, they may be defective and may require amendment.

Annotations.

"Ne quid nimis."

THE HOT CROSS BUN.

DIETETICALLY considered the hot cross bun differs in only one regard, but perhaps an important one, from bread, inasmuch as the Good Friday bun contains a fair sprinkling of spice, generally in the shape of allspice or pimento. Otherwise the ingredients are the same and the mode of preparation is the same—that is to say, a dough is prepared, yeast is added, and the "sponge" is then cut up into buns and baked. The hot cross bun, in a word, is practically bread plus a condiment. The rôle of spices and condiments in food is important. They improve appetite and increase the digestive power by inducing a flow of digestive juice. They are, as a rule, therefore, of service to those who, from illness or other cause, have a dull appetite. The use of a condiment may almost be regarded as superfluous in the case of persons with vigorous appetite and sound digestion, while spices and sauces must be studiously excluded from the diet of any who are suffering from catarrh of the stomach or intestine, since, after all, condiments are in reality irritants. The custom of eating hot cross buns on Good Friday, which is, of course, a day nearing the end of a fasting season, may be regarded as having for its object, perhaps, the preparation for the feast day, or else the intensification of the discipline which the partial abstinence from food entails. To sharpen the appetite during a period of fasting is clearly calculated to make the ordeal of self-denial more severe. The spices would aggravate the craving for more food. Whether this was the original idea of the spiced bun for eating on Good Friday may be open to question, but such a view at all events suggests itself when we come to consider the part played by spices in dietetics, and it is a significant fact that spices, as a rule, are rare constituents of buns.

RECORDS OF SMOKE.

THE deleterious effects of coal smoke escaping into the atmosphere have often been referred to in our columns and the discharge of black smoke from a chimney has been made a statutory offence. The prosecution of offenders is, however, not infrequently difficult on account of conflicts in the evidence as to the density of the smoke emitted. Writing on this subject in the *Engineering Supplement* of the *Times* of March 20th, Mr. James Swinburne points out that the excellent smoke chart of the Institution of Civil Engineers is imperfect, because it is almost impossible to compare smoke seen against the sky with a shade on paper which is not only in close proximity to other darker and lighter shades but is not really comparable at all. He says that this difficulty may be overcome by having the smoke scale made on glass or transparent celluloid which can be held up in such a way that the smoke can be compared with the progressive series of tints forming the scale. These scales might be standardised so that different observers might have exactly similar tints before them, and a further

improvement would be to photograph the smoke scale together with the smoke which is to be tested. They then both receive the same treatment and the smoke on one print is compared not with the smoke on another print but with its own smoke scale. Thus, smoke on one print may be very light, the scale being very light too, so that the smoke corresponds with the scale at, say, 0.4, which means that the smoke stops four-tenths, or 40 per cent., of the light. On another print, taken by someone else at the same time, the smoke may look very dark, but the scale will look very dark too, so that the smoke will still correspond with the part of the scale marked 0.4. Mr. Swinburne further describes how a smoke scale, with its varying tints, is prepared on a photographic plate and how different smoke scales can, for purposes of comparison, be calibrated in terms of their light-stopping power. He says that for photographing a column of smoke which is to be tested a pocket quarter-plate camera does quite well, its only drawback being that the shutter has only one speed, which will probably be too fast for smoke photography.

INFANTILE MORTALITY IN SCARBOROUGH.

It is much to the credit of the town council of Scarborough that it has preserved careful records of the mortality occurring in that beautiful and fashionable seaside resort for each week of the last 30 years. The result is that the present medical officer of health, Dr. John Knight, has recently been able to present to the council an analysis of the infantile mortality there prevailing in each year from 1876 to 1905. Dr. Knight has brought to his task a marked degree of administrative knowledge. We have nothing but commendation for the telling way in which he has marshalled his data or for the straightforward manner in which he has ventured to point out to his authority the serious fact, for which it is alone responsible, that in spite of the great natural advantage of its seaside position Scarborough still suffers its infant population to die almost as rapidly as does the infant population of England and Wales generally, including, of course, the vast aggregate of industrial communities which possess none of the advantages conferred by proximity to the sea. The report is replete with tables and with well-constructed diagrams, and the accompanying letterpress furnishes an instructive commentary on the facts thus graphically represented. We note that the tables of infantile mortality are drawn up according to the new forms recently issued by the Local Government Board and are identical with the useful series of tables on infantile mortality contained in the last annual report of the Registrar-General. Dr. Knight directs attention to the fact that although in the last 30 years there has been a steady fall in the mortality of other sections of the community, the infantile death-rate has, nevertheless, remained almost stationary. The various causes for this up-keep of infantile mortality in Scarborough are ably discussed and its incidence is shown on the successive weeks and months of the first year of infant life. It is, however, to the "recommendations" made by Dr. Knight for the reduction of the present excessive mortality that we desire particularly to direct attention. After stating his conviction that the complex problem of infantile mortality admits of solution only by attacking it from all sides—every agency for the prevention of disease, the protection of feebleness, and the promotion of health being called into play—he shows that the waste of infant life stands in close relation to the social condition of the parents, being greatest here, as elsewhere, among the poorest classes of the community. Two obvious improvements are indicated in the report as specially necessary in Scarborough at the present time: (1) the systematic reduction in number

and the ultimate abolition of the privy system; and (2) the more frequent removal and the more efficient disposal of house and street refuse. The pollution of the soil which is known to play an important part in the causation of infantile diarrhoea may be lessened by the prompt removal of excretal and other domestic refuse from amidst the homes of the people. Dr. Knight does not shrink from telling his authority plainly that both these measures are well within the competence of the corporation without seeking further powers from Parliament for that purpose. General measures, however, must be supplemented by action regarding the particular infant. And here it is obvious that before any procedure of this kind can be instituted the sanitary authority must become aware of the existence of the individual infant but in this respect the present law is defective. Not until the lapse of six weeks after the event need the birth of a child be registered, although one-third of the infantile deaths occur under the age of one month. As in these cases the birth and the death are registered at the same time, it follows that no control can at present be exercised over the lives of one-third of the infants dying within their first year. This defect in the law has been remedied in Huddersfield, and, we believe, in a few other towns, by a system of voluntary notification whereby intimation to the authorities of the occurrence of a birth is encouraged by the offer of a small fee for each notification within 48 hours of the event. This duplication, however, of methods for securing necessary information seems to us clumsy and unnecessary and we are glad to find, from the recent reports of the Registrar-General, that an amendment of the present arrangements for birth registration is now under his consideration. But the uselessness of even a prompt notification of births is clearly recognised by the Scarborough medical officer of health unless definite administrative action follows immediately on its receipt. Thus the minimum of such action would, in Dr. Knight's judgment, consist in the distribution to each person concerned of a card or leaflet containing hints on the feeding and rearing of infants. But as most of the waste of infant life depends on ignorance of parents the better plan would be the appointment of a lady health visitor, as in Manchester and some other towns, who would visit the mother and give directions for the welfare of her offspring and herself.

A NEW AIR PURIFIER.

We have received particulars of a new air purifier which has been applied with conspicuous success to the refrigerating room of a large brewery at Newark-on-Trent. It is suggested to us by Mr. Ernest Ringrose, L.R.C.P. Lond., M.R.C.S. Eng., that this method is eminently fitted for use if not in the wards of hospitals at least in the operating theatres. The Warwick air purifier (as the apparatus is called) consists of a large box containing metal trays which are as wide as the box but not so deep, so that one tray can be pushed to the back, leaving a small space in front leading to the tray below. The next tray is placed forward, leaving the vacant space at the back, and so on through a series of trays which, acting as baffles, compel the air to flow over a relatively large surface. At the inlet there is a small skeleton drawer fitted with a sheet of muslin which screens coarse particles out of the air. The metal trays contain a layer of glycerine sprinkled with a little powdered sulphite (presumably) of sodium. The glycerine arrests the organisms and the sulphite prevents their development. Actual experiments showed that the purifier removed on an average 99.5 per cent. of the organisms present in the air admitted from the outside, the only organisms which eventually got through being moulds. Neither yeasts nor bacteria appeared even on prolonged exposure in the refrigerating room.

A photograph showing three bottles containing wort gelatin has been submitted to us. No. 1 was exposed to the outside air on the east side of the premises and No. 2 to the outside air on the west side of the premises. No. 3 was exposed in the refrigerator room. Growth took place freely in No. 1 and No. 2, but No. 3 is practically free from any development. This is very clearly seen in the photograph. The apparatus stands about four feet high and is about three feet square and in section and contains 11 trays. In the experiment just cited 20,000 cubic feet of air were passed through this apparatus per hour and apparently only one organism per 500 cubic feet of air escaped the joint action of the glycerine and sulphite in the tray. Mr. Ringrose suggests that this air purifier would prove a valuable accessory to every hospital, so that the benefits to mankind which have been brought about by the labours of Lord Lister may in this way be enhanced.

DEATH CERTIFICATION.

THE Lord Chancellor on Friday last received a joint deputation from the London County Council and the Medical Legal Society which was introduced by Sir William J. Collins, M.P. Mr. H. T. Anstruther handed to the Lord Chancellor a report dealing with the necessity for obtaining the appointment of medical investigators who might make preliminary inquiries in cases where an inquest appeared desirable. Sir William Collins spoke upon the imperfections and the dangers of our present lax system of death certification and pointed out in how many cases the drawing up of a preliminary report in cases of suspected unnatural deaths was left to the unskilled coroners' officers. Mr. John Troutbeck, coroner for the South-Western District of London, supported these views. The Lord Chancellor, in reply, promised to give his most serious consideration to the matter, which he considered to be of real and great importance, and added that without loss of time he would investigate the facts personally. We can add our wishes to those of the members of the deputation that our present very haphazard and even dangerous system of death certification may soon be superseded by some better method.

INDUCTION OF LOCAL ANÆSTHESIA BY COCAINE CATAPHORESIS.

CATAPHORESIS, or the introduction of drugs into the system by electricity, is a method which promises much and is still in its infancy. In the *Journal of the American Medical Association* of Feb. 23rd Dr. D. T. Quigley has reported very satisfactory results from the induction of local anaesthesia by cocaine cataphoresis. He claims that under it half the operations of surgery could be performed with greater safety and less worry to both the surgeon and the patient. He has used the method for removal of tumours of the breast and epithelioma of the lip, herniotomy, removal of hæmorrhoids, and destruction of moles. It may be employed for any operation which does not involve the great cavities of the body or in which the field does not extend too far from the surface to be reached by cocaine. The technique is as follows. A piece of aseptic gauze is folded four times and cut of the size of the part to be operated on. The gauze is saturated with a solution composed of cocaine hydrochlorate, one and a half drachms, solution of adrenalin (1 in 1000), two drachms, in sterile water to 2 ounces. The adrenalin constricts the vessels and renders the operation almost bloodless, but secondary hæmorrhage occurs in about 1 case in 4. The gauze is covered with metal foil and connected with the positive pole of the battery. The circuit may be completed by the patient holding in his hand a wet sponge electrode connected with the negative pole, or better, a large pad

electrode may be attached to the skin by a bandage near the seat of operation. If the operation is on a limb the negative electrode may be attached on the opposite side to the positive one, and both may be held in position with the same bandage. But care must be taken that the skin between the poles is perfectly dry; otherwise the current will follow the wet surface and not pass through the skin. The time required is from 15 to 30 minutes and may be longer if a deep effect is necessary. Dr. Quigley has never observed any toxic effects from absorption of cocaine. A battery of 20 or 30 wet or dry cells should be used. A rheostat to control the current is useful but not necessary, as this may be accomplished by diminishing or increasing the number of cells. The current should be as strong as the patient can bear without discomfort; a milliamperemeter is unnecessary. After the current is turned on the edge of the foil-covered gauze should be turned every five minutes and fresh solution applied, as the gauze should be well saturated to get the best effect. In operating on hæmorrhoids the gauze should be applied to a cone-shaped metal electrode large enough to have a dilating effect on the sphincter when applied to the anus. This electrode should have a wooden or hard rubber handle and be pressed firmly into the anus by an assistant. In from 20 to 30 minutes the sphincter will be considerably relaxed and the hæmorrhoidal area anæmic and numb. If the hæmorrhoids are large and pendulous the base may be grasped gently between the blades of a forceps, each blade being wrapped with gauze saturated with the solution. The handle of the forceps is then attached to the positive pole and the circuit is completed. In a few minutes the tumour can be cut off without pain. In operating on navi the area should be anaesthetised as described. Then the navi is transfixed just below the surface with straight needles about one thirty-second of an inch apart. A fine wire is threaded through the eyes of the needles and attached to the negative pole. The current is passed until the spaces between the needles look seared and pale. This destroys the navus and does not leave a scar. The same method may be used for moles but any large hairs in them must be first destroyed by the electric needle attached to the negative pole. This method of inducing local anaesthesia is preferable, Dr. Quigley considers, to Schleich's infiltration method because it is entirely painless, does not involve distension of the tissues, covers a wide area if necessary, and so far has not produced toxic effects. Dr. Quigley does not state, however, the number of cases in which the method has been employed. The anaesthesia lasts over an hour, so that ample time for the operation is afforded.

THE PHARMACOLOGY OF AN ALKALOID FOUND IN FRESH VALERIAN JUICE.

IN THE LANCET of May 20th, 1905, p. 1367, reference was made to the greater activity of fresh valerian juice as compared with the ordinary galenical preparations obtained from dried valerian root. We learn from the *Comptes Rendus* of Jan. 21st that the fresh juice has been examined by M. J. Obevalier with the result that it has been proved to contain an alkaloid and a glucoside, together with some resinous matter. A pharmacological investigation has shown that the special action of the fresh juice is due to the presence of the alkaloid and the glucoside, which are unstable bodies and undergo decomposition during the drying of the roots and the manufacture of the galenical preparations of valerian. As the alkaloid is present in the plant to the extent of only 0.015 per cent. its chemical identification will have to be delayed until sufficient is obtained for a complete examination. The pharmacological investigation of the alkaloid was conducted on dogs. It was found to exert an energetic action upon the bulb and the

medulla oblongata. The predominating action of the alkaloid is depressing and paralysing and is purely central. The depressing action is not confined to the bulb but extends along the whole of the cerebro-spinal axis. The diminution of the excitability of the cerebral centres, following the administration of the alkaloid, points to the value of preparations of fresh valerian root in the treatment of hysteria and especially of epilepsy.

CELEBRATION OF LORD LISTER'S EIGHTIETH BIRTHDAY.

A MEETING of the committee appointed to make a fitting recognition of this anniversary will be held at the Royal College of Surgeons of England, Lincoln's Inn Fields, on April 4th, at 5 o'clock in the afternoon. The business will be: 1. To consider the form and method of republication of Lord Lister's scientific papers. 2. To appoint an editorial committee to undertake the same. 3. To send greetings to Lord Lister on his birthday, April 5th, and to acquaint him with the proposals of the committee. Any communications on the subject should be addressed to Dr. Charles J. Martin, F.R.S., secretary (*pro tem.*) of the committee, at the Lister Institute, Chelsea Gardens, London, S.W.

THE "WHITE LINE" AS A SYMPTOM OF DISEASE OF THE SUPRARENAL CAPSULES.

At a meeting of the Société Médicale des Hôpitaux of Paris on Feb. 8th M. Siredey and M. O. Tinel called attention to the phenomenon known to French clinicians as the "white line" in the diagnosis of disease of the suprarenal capsules. This phenomenon was first described by M. Sergent in 1903.¹ It is the converse of the meningeal streak. Like the latter, it is produced by drawing the finger-nail across the skin of the patient's abdomen. After a period, of from 30 to 60 seconds a white line appears which lasts from two to five minutes. M. Sergent has found it in Addison's disease and in a variety of conditions—the specific fevers, septicæmia, influenza, poisoning by corrosive sublimate, exhaustion from over-exertion—which were all marked by low arterial tension. He thinks that the low tension is due to some alteration in the cells of the suprarenal capsules, a conclusion which was confirmed by the fact that the administration of suprarenal extract was followed by the disappearance of both the "white line" and the low tension. He therefore regarded the "white line" as a symptom of suprarenal insufficiency and insisted upon its importance in the diagnosis of all affections of the suprarenal capsules. His observations have been confirmed by other French writers. At the meeting mentioned above M. Siredey and M. Tinel reported an interesting case of tuberculous meningitis in which the meningeal streak was replaced by the "white line" in consequence of involvement in the disease of the suprarenal capsules. A man, aged 47 years, was taken to hospital comatose. The history, given by his son, was vague. It appeared that the patient had suffered from pleurisy 10 months ago, from which he rapidly recovered. For some weeks he had shown signs of weakness, and three days before admission he was found unconscious. On admission he was in a state of profound coma, with carphology and subultus tendinum. Trismus, rigidity of the neck, and Kernig's sign were found. The pulse was small and the respiration was irregular. Examination of the chest showed generalised bronchitic râles and consolidation at the apices. On attempting to obtain the meningeal streak a thin rose line was produced, which rapidly became white and then slowly broadened, so that after half a minute it was from one to two

centimetres in breadth; it disappeared after two or three minutes. This phenomenon caused suprarenal disease to be suspected. With Potain's sphygmomanometer the vascular tension was found to be only 12. There was no pigmentation of the skin nor were spots present on the mucous membranes. Death occurred on the following day. The necropsy showed meningeal, pulmonary, and peritoneal miliary tuberculosis. Neither the kidneys nor the liver showed any tubercles. But the suprarenal capsules contained large tubercles. The left capsule contained three tubercles of the size of a pea and several smaller ones; the right capsule was less involved. Thus M. Sergent's conclusion as to the value of the "white line" as a symptom of suprarenal disease was confirmed.¹ In the discussion which followed M. Sergent referred to the case of a girl who presented symptoms of meningitis. He could not obtain the meningeal streak but after some seconds a white line appeared which lasted two or three minutes. The patient died and the necropsy showed absence of disease of the meninges but complete caseation of the suprarenal capsules. In connexion with this case M. Sergent has described a pseudo-meningeal syndrome due to suprarenal insufficiency in which the "white line" is present. As to the mechanism of the production of the "white line" it appears to be a reflex spasm of the capillaries provoked in conditions of low vascular tension and vaso-dilatation.

WHOLE MEAL v. WHITE BREAD.

The suggestion of the Bread and Food Reform League that "most people can digest the whole of the wheat grain; if it be ground of a uniform very fine quality of properly selected wheat," would appear to receive endorsement, in some experimental work on the digestibility of foods which has been undertaken by Professor Snyder on behalf of the United States Department of Agriculture. In a pamphlet written by Miss May Yates, the honorary secretary of the league, the chief points of this inquiry are brought out but the general result appears to be that it is essential that the whole meal should be ground and re-ground until it will all pass through a fine sieve and thus that a mechanical condition should be obtained which will enable the gastric juice to act on all the nutrients. According to Professor Snyder, there is more protein, pound for pound, in entire wheat than in patent flour, and therefore if in these experiments the body secured less protein and energy from the coarse flour than from the fine flour it was simply because the meal was not ground fine enough. An experiment showed that whereas from 2463 grammes of patent white bread (containing 133.2 grammes of protein with a loss of 26.9 grammes of protein) only 106.3 grammes of protein were utilised, while with a consumption of 1558 grammes of bread made from flour with the addition of 14 per cent. of bran (containing 148 grammes of protein, with a loss of 14.9 grammes) there were assimilated 133.1 grammes of protein. In other words, a consumption of more white bread amounted to an appropriation of 26.8 grammes less of protein than from a smaller quantity of bread with 14 per cent. of finely ground bran. In addition to this, it is well to bear in mind the fact that with the rejection of the bran an enormous loss of valuable mineral material is entailed. Thus there is nearly double the amount of lime salts in whole wheat meal than there is in fine white flour, and one pound of whole wheat meal has 119 grains of mineral matter and 59.1 grains of phosphoric acid, whilst one pound of white flour has only 49 grains of mineral matter and 21.3 grains of phosphoric acid. This subject has, of course, been very widely debated and it seems to us that there is something to be said on both sides. There can be little doubt that the conclusion hitherto reached that the defective absorption of

¹ Presse Médicale, Nov. 25th.

wholemeal bread is due to the large amount of cellulose or branny particles which it contains is correct. The contention is probably also correct that this defective absorption is to be attributed largely to incomplete grinding and that the absorption would be greater if the flour was reduced to a very finely divided powder. Even, however, when the branny particles are reduced to a fine powder careful experiments have shown that bran is never so easily absorbed as flour.

THE MANUFACTURE OF ELECTROLYTIC DISINFECTING FLUID AT POPLAR.

THE electrolytic apparatus which was installed at Poplar in February, 1906, under the direction of Mr. F. W. Alexander, the medical officer of health of that borough, for the production of disinfecting fluid has now been in going order for over a year and a copy of the balance sheet, representing the cost of the manufacture, has reached us. Mr. Alexander states that in comparing the expenditure of the year 1906 with that of 1905 it will be seen that there has been a saving of £265, and if the sum of £30 paid to the electricity department as rent and supervision be omitted from the account there has been brought about a saving of nearly £300 compared with the cost of carbolic disinfectants, and this amount does not include any charge for the quantity furnished to the guardians, as the fluid was supplied to them gratis. The initial outlay amounted to about £583. Mr. Alexander considers that "the step initiated has proved itself overwhelmingly satisfactory from every point of view, particularly that of the public health of the district during the period for which the plant has been at work." The annual notification rate per 1000 living in the borough was 6.2 against that of 7.5 for London for the year 1906, the death-rate of the borough being 17.5 per 1000 living. It may be added that the fluid prepared in October, 1906, by the improved method has remained constant in strength as regards available chlorine up to March, 1907.

GROCCO'S SIGN IN THE DIAGNOSIS OF PLEURAL EFFUSION.

IN 1902 Grocco of Florence described a new sign of pleural effusion—a paravertebral triangle of dulness on the opposite side. He found that when percussion is performed from above downwards along the vertebral spines while the patient is in the sitting position dulness, at first relative and then absolute, is obtained. Similarly, on percussing downwards on the healthy side in lines parallel to the spine a paravertebral triangle of dulness may be defined. One side of the triangle is represented by the spines of the vertebrae, the base by the line of the lower border of thoracic resonance for a distance of two, three, or more centimetres from the spine, and the outer side by a line rising from the outer extremity of the base obliquely to unite at an acute angle with the median line at the upper limit of dulness. By radiographing a cadaver in which the chest on one side had been filled with a solution of acetate of lead Grocco showed that the shadow of the solution extended sufficiently past the middle line to account for the triangle of dulness. He claimed that this sign was of value in distinguishing pleural effusion from pulmonary consolidation. This has been confirmed by many observers. An important article on the subject, by Dr. W. S. Thayer and Dr. M. Fabian, has been contributed to the *American Journal of the Medical Sciences* for January. In 30 out of 32 cases of pleural effusion they clearly demonstrated a paravertebral triangle of dulness. In one of the remaining cases the effusion was small and the examination was rather hastily and imperfectly performed but a small indefinite area of dulness was found. In the other case the absence

of the paravertebral triangle was explained by the position of the exudation, which was an interlobar empyema. The sign may therefore be regarded as constant in cases in which there is free fluid in the pleural cavity. Dr. Thayer and Dr. Fabian also found that over the paravertebral triangle the respiratory murmur is often suppressed and similar to that heard over the effusion. Egophony or a nasal quality of the vocal resonance may also be heard. The sound produced by striking a coin on the front of the chest below the level of the effusion shows the same metallic ring over the triangle as over the effusion on the affected side. These signs may be so marked as to make possible the definition of the triangle by auscultation. When the patient lies on the affected side the triangle diminishes or disappears and when he assumes the erect posture or lies on the other side it returns. In three cases of encapsulated effusion the paravertebral triangle proved of diagnostic value. Thus, a man, aged 23 years, had a severe attack of typhoid fever. An area of absolute dulness was found below the angle of the right scapula with the patient lying on his left side. The dulness ended sharply at the posterior axillary line. Over the dull area vocal fremitus was diminished, respiration was distant and tubular, the respiratory murmur had a somewhat metallic quality, and the voice sounds were nasal. On the left side was a paravertebral triangle of dulness measuring eight by five and a half centimetres. Puncture of the dull area yielded purulent fluid. Operation showed an encapsulated empyema. In cases of pneumonia a small strip of dulness may be found along the spine on the opposite side but Dr. Thayer and Dr. Fabian were able to detect only once anything approaching a paravertebral triangle, and in this the dulness was not very definite and showed little or no alteration on change of posture.

THE INSANITARY CONDITION OF LONGTON.

A Local Government Board inquiry has been held recently at Stoke-upon-Trent to consider the question of the federation of the municipal boroughs of Stoke-upon-Trent and Longton and the urban district of Fenton into one county borough, when some remarkable evidence was given as to the insanitary condition of Longton. Dr. J. W. Dawes, the medical officer of health of this borough, said that the population was estimated at 36,797 and the number of houses at 7826. The birth-rate was 36.4 and the average death-rate for ten years was 22.4. The infant mortality in ten years gave a return of 228.7 per 1000 births. He considered that there had been great improvement in the sanitary condition of the town, but admitted that the death-rate and infantile mortality were both very high. From his evidence it appeared that property owners on the corporation had prevented the conversion of privies into water-closets. In 1903 he had to report on a well on the corporation sewage farm which was used in connexion with the dairy on the farm, from which milk was supplied to the inhabitants of the town. Nothing was done to remedy this state of things till 1906 when the waterworks supply was put in and he did not know whether or not the well was still in use. When questioned as to cowsheds within the borough he admitted that there was one registered for 19 cows where 38 were kept. In this case the air space was 420 cubic feet per cow and the sheds were dirty, dark, and badly ventilated, whilst the drainage was imperfect. He knew another cowshed registered for 22 cows where 42 were kept and where the air space was 300 cubic feet per cow. As to common lodging-houses there were two or three places used as common lodging-houses which were not registered, and he knew a lodging-house registered for 25 lodgers where three of the sleeping-rooms had no fireplace or substitute for

ventilation. Dr. George Reid, medical officer of health of the county of Stafford, said he could hardly find words to describe the condition of Longton from a sanitary point of view. He had inspected the common lodging-houses, slaughter-houses, and dairies and cowsheds and speaking generally he did not know any other town in Staffordshire even approaching Longton. He spoke of overflowing ashpits, badly paved yards, and defective and dirty cesspools and closets, and described one court containing 14 houses which were dilapidated, filthy, and badly drained, with foul privies six feet from the back doors of the houses. Longton had a refuse destructor but it was either not made use of or it was not capable of doing the work because of the overflowing condition of the ashpits and—where there were ashbins—the ashbins. He confirmed Dr. Dawes's statements as to the condition of cowsheds and lodging-houses. With regard to infantile mortality, for Stoke it was 170 per 1000 births, for Fenton 194, and for Longton 229, that being the average for the ten years 1896-1905. Some little time ago Longton appeared to have the largest infantile mortality in England and both this and the high death-rate must be due to a large extent to the insanitary condition of the town.

EPIDEMIC CEREBRO-SPINAL FEVER.

THE notifications of cerebro-spinal fever indicate a progressive extension of the disease throughout the country without exceptional prevalence in any fresh locality. A large number of sanitary authorities have now made the disease compulsorily notifiable. The public health committee of the London County Council announces that nine cases have been notified in London since March 12th, but one of them was eventually found to be a different disease. Cases have occurred at Horton, near Leek in Staffordshire, and at Bebside, near Blyth in Northumberland. In Glasgow the only information obtainable at present is that there were 102 cases under treatment on March 22nd. Cases have also occurred at Falkirk, at Leith, at Govan, and at Denbeath in Fifeshire. In Belfast there were 39 patients under treatment on March 22nd; 8 new cases were reported on March 25th, making since the commencement of the epidemic a total of 215 cases, among which there have been 115 deaths. On March 20th a case was discovered in the workhouse at Cork.

THE death is announced, in his seventy-first year, at Wiesbaden, of Professor Ernst von Bergmann, the eminent German surgeon. We hope to give an extended account of his career in a future issue.

THE Department of Public Health of Queensland, in a bulletin dated Feb. 9th, states that no further cases of plague have occurred in the New Farm area. 3 other cases, however, have been notified—viz., Case 20, a male, aged 20 years, who was attacked on Jan. 31st; Case 21, a female, aged 58 years, who was attacked on Jan. 30th and died on Feb. 4th; and Case 22, a male, aged 50 years, and attacked on Feb. 4th. A bulletin, dated Feb. 16th, reports 1 further case, No. 23, a male, aged 19 years, who was attacked on Feb. 7th. A case of plague is also reported from Ipswich—viz., a male, aged 35 years. The case was not reported till after the patient's death. As regards Port Douglas 6 fresh cases occurred during the week ending Feb. 9th but no further cases for the week ending Feb. 16th. As regards the Mauritius a telegram from the Governor received at the Colonial Office on March 22nd states that no cases of plague were reported during the week ended March 21st.

THE Thirty-sixth Congress of the German Surgical Society, the Sixth Congress of the German Society for Orthopaedic

Surgery, and the Third Congress of the German Roentgen Society will all meet in Langenbeck House, Berlin, in the beginning of next week.

AT an extraordinary Comitia of the Royal College of Physicians of London held on Monday last, March 25th, Sir Richard Douglas Powell was re-elected President.

THE SECOND INTERNATIONAL CONGRESS ON SCHOOL HYGIENE.

UNDER the Presidency of the Lord Mayor a meeting was held at the Mansion House on March 20th to promote the interests of the forthcoming Congress on School Hygiene which is to be held in London in August of this year. Among those present on the dais were Sir Lauder Brunton, President of the Congress, Lord Ramsay, Sir John Cockburn, Dr. T. J. Macnamara, M.P., Sir Richard Martin, Sir Edwin Brabrook, the Greek, Chinese, Uruguayan, and Serbian Ministers, the Agent-General for Natal (Sir Thomas E. Fuller), the Agent-General for South Australia (Mr. J. Jenkins), Sir Cuthbert Quilter, Dr. J. Kerr, and Mr. Alfred Mosely.

THE LORD MAYOR, in opening the proceedings, said that the meeting was one of the utmost importance to the health of infants and school children.

SIR LAUDER BRUNTON remarked that the congress was an assemblage from every civilised country in the world of people who were interested in the health of school children. Of the subjects to be dealt with by the congress, the first group was concerned with the best methods of training for the minds and bodies of healthy scholars in and out of school, the second group with children who were defective in body or mind, the third group with the important subjects of medical inspection, the instruction both of teachers and of children in the laws of health, and the health of the teaching profession, and the fourth with residential schools, school buildings, and equipment. With regard to medical inspection he observed that it was fervently hoped that the Bill for the compulsory medical inspection of children which was before Parliament would soon become law, for medical inspection was the groundwork upon which the superstructure of school hygiene must be built. Without medical inspection no proper system of physical education was possible. Defective sight alone was the cause of much misery to children at school, for it not only hindered their learning but caused them sometimes to be punished for stupidity and led to most distressing headaches which were a torture to the child. Schools, too, might become a hot-bed of infection for a whole district. As a result of the conference they would probably obtain a scheme of physical training superior to any in existence. The mental and bodily advantages to be derived by the children in this country from information afforded by the congress might not only prevent them from falling into the ranks of the unemployed, but might, in many cases, prevent them from becoming criminals.

Dr. MACNAMARA said that much had been done in the interests of the child during the past 30 or 40 years, but the time had arrived when it was necessary, in the interests of the nation as well as of the children, that the care of the child must be placed on an accurate and scientific basis. The teacher was placed at a great disadvantage by reason of the lack of scientific data upon which to base his methods of dealing with children who showed physical defects, and there was also need for practical examples being set before the child at school in the way of perfectly constructed buildings from a sanitary point of view.

SIR JOHN COCKBURN said that the care of the children was one of the most important problems that could confront any people. Nations depended for their existence on the way in which they dealt with the children who would be the adults of the next generation.

SIR RICHARD MARTIN, in appealing for subscriptions, pointed out that the money spent on the object which the meeting had met to promote was a sound investment and not a charity, for the result of the congress would be that the educational authorities would learn how best to spend the ratepayers' money economically.

Mr. ALFRED MOSELY, in moving a vote of thanks to the

Lord Mayor, referred to his investigation in America where he found educational methods much in advance of English methods and said that it was a very false kind of economy to neglect the health of the future generations.

Mr. SYKES, President of the National Union of Teachers, seconded the proposition, and a unanimous vote of thanks was accorded to the chairman with acclamation.

The LORD MAYOR briefly replied and the proceedings terminated.

Looking Back.

FROM

THE LANCET, SATURDAY, March 23th, 1829.

FOREIGN DEPARTMENT.

CASE OF POISONING BY CHEESE.

DR. WESTRUMB of Eimbeck, in the kingdom of Hanover, was, on the 10th of November, 1826, called to a family, consisting of a middle-aged man, his daughter, a girl of ten years, and a female relation, about sixty years of age, who, an hour after having eaten of a cheese lately bought, had been suddenly seized with symptoms of poisoning, as violent colic pain, vomiting, diarrhoea, tenesmus, &c. On his arrival, he found them with the abdomen swelled, very painful on pressure, especially in the hypochondria, the pulse very small and frequent, the pupils dilated, and complaining of violent headache, vertigo, great debility, and sickness; the rejected matter had the smell of cheese, and was apparently of an alkaline nature. An emetic, and aperient injections, were immediately ordered, when Dr. Westrumb was sent for to another family, consisting of four persons, who, a short time after, having eaten some cheese bought at the same place, had been simultaneously affected with similar symptoms, but in greater intensity. Besides the remedies used in the first cases, very strong coffee, and a solution of boracic acid were ordered. After this treatment had been continued for two days, five of the patients perfectly recovered; in the other two, in whom the symptoms had been most violent, the affection of the head attained to such a degree as to require the application of leeches, and cold affusion; after about a week, they were also convalescent. M. Sertuerner having been requested to examine the substance which had been the probable cause of the symptoms of poisoning, came to the following results: under the continued action of alcohol, two different substances were obtained, the one of a black colour was precipitated, the other of an oily consistence, brown colour, astringent, nauseous taste, and a very penetrating, rancid smell, collected on the surface of the liquid; it was found soluble in hot water and alcohol, changed the colour of litmus to red, and, when mixed with alkalis, formed a soapy mass. The black substance was liquid, insoluble in hot water and alcohol, and being submitted to heat, gave an extract of an acid nature, caseous smell, and containing an ammoniacal salt, the acid of which could not be ascertained. The maceration of the residuum in hot alcohol produced, at first, no change; but after some time a greyish white substance spontaneously precipitated from the alcohol, which melted at a slight degree of heat, and was also apparently of an acid nature. The three substances, thus prepared, but especially the two former, were found to be very powerful poisons; fifteen grains of them injected into the stomach of a large dog, caused a violent inflammation of the intestinal canal, and the subsequent death of the animal.

Dr. Westrumb regards the deleterious principle in the cheese as belonging to the class of narcotico-acid poisons, and attributes its production to the following causes:

1. The milk being furnished by cows, which have eaten of poisonous vegetables; this will, however, be but very seldom the cause, as, under these circumstances, the secretion of milk is greatly diminished, or even entirely suspended.

2. The preparation or conservation of the cheese in metallic vessels. In some cases of poisoning by cheese, traces of copper and tin were actually discovered in it, although but in very small quantities. The Gazette de Santé, of 1766, No. 22, contains a case of this kind.

3. Adulteration of the cheese, especially with the seeds of

hyosciamus, which had inadvertently been mixed with it, instead of cumin seeds.

4. The formation of a poisonous substance by the chemical decomposition of the cheese. This seems to have taken place in most instances, and, as is shown by M. Sertuerner's analysis, did so in those just described.—*Horn's Archiv.*

"SANATORIA FOR CONSUMPTIVES."

UNDER this title Mr. EDWIN T. HALL, Vice-President of the Royal Institute of British Architects, on March 22nd, before the Architectural Association, Westminster, read a paper which had many points of medical interest and led up to an interesting discussion.

Mr. Hall's paper was mainly devoted to a description of various existing sanatoria in this country and abroad and a number of interesting photographs and plans were exhibited on the walls of the room and also by means of the lantern. After discussing the various points brought out by the illustrations in an instructive manner, Mr. Hall, whose claim to having given a great deal of thought to the question is evidently justified, came to some important conclusions on the problem of how to supply cheap sanatoria. Huts, he said, were cheap but very temporary, and cost a great deal to maintain, while they also might offer special risks. He then showed on the screen illustrations of the kind of sanatorium which he considered would be the cheapest permanent form for cases of pulmonary tuberculosis. He described the buildings as made of an inclosing material, including that for floors, which is non-combustible and impervious to rain and vermin. It is made in dry slabs of standard size, which are practically universal in application for the unit. "A sanatorium on these lines," he said, "complete with all essential administrative buildings to suit any required number of beds, with drains, fittings to kitchen and laundry, and water storage, can be erected on a suitable and reasonably accessible site at a cost of about £85 to £105 per bed, depending on its size. I call the design the standardised expanding sanatorium because if a small institution erected on these lines requires to be extended to meet growing wants, this can be readily accomplished by adding units to the wards and administration." As examples of what could be done, Mr. Hall quoted one sanatorium of 16 beds with its appropriate administration to cost about £1680, one of 32 beds to cost about £3170, and one of 48 beds to cost about £4080. None of these buildings compete with the large permanent sanatoria which will remain. Mr. Hall's aim has been different. "In June, 1905," he said, "a profitable discussion of the whole subject took place in London, and Dr. Heron remarked that poor consumptives should be sent into sanatoria for their own sakes and for the sake of the healthy community, which could not be done if sanatoria were built costing £200 to £300 per bed. A sanatorium well equipped for the service of the poor should not cost more than £80 per bed."

Mr. Hall thought that his standardised sanatoria would meet the views of Dr. Heron. The buildings had in them nothing in common with the temporary wood hut or galvanised iron buildings with timber construction and cavity walls and roofs. They had solid thin walls, roofs, and floors, with no cavities. They have smooth internal surfaces, avoiding the expense of plaster or wood covering. These surfaces might be left bare or might be distempered only, painted. The drainage was designed for soiled water only, which if no sewers were available would be taken into cesspools and emptied by closed suction carts. A water-supply was assumed to be available, either from public mains or a local pure stream or other source. Fireplaces in all rooms were provided to avoid the great expense of an engineering plant. A gas-supply was required for heating bath water by geysers, and gas or oil might be used for lighting. All the joinery required could be prepared in labour centres and carted on to the site ready for immediate erection. In all cases the sanatorium was divided into units of eight beds, each unit containing six wards with single beds and one with two beds. With a total of only 16 beds it was assumed that the medical work would be done by a non-resident physician, the patients being in charge of a qualified matron with nurses. With 32 patients, a resident medical man was provided for in addition to the matron and the nurses and servants were increased. With 48 patients quarters were provided for two medical

men, a matron, and an assistant matron or housekeeper, with a larger staff of nurses and servants. A small consulting-room and a waiting-room were also provided. All the buildings were one-storied. All patients' rooms faced south-south-east or south-south-west; all staff rooms faced either south or east and west so that all got ample sunlight. All rooms were approached by corridors or covered ways, protected from rain. All patients' rooms had glass-verandah shelters on the southern side. The open-air treatment was fully adopted.

Colonel GERRARD OLARK, in proposing a vote of thanks to Mr. Hall, asked whether the estimates given for cheap sanatoriums included furniture.

Mr. HALL replied that the estimates were for buildings alone.

Dr. H. T. BULSTRODE said that in commenting upon the lecturer's paper he was somewhat handicapped by reason of his official position. He had visited almost every one of the sanatoriums, both in this country and abroad, mentioned by Mr. Hall and he was at the present moment preparing a report to the Local Government Board on the question of sanatoriums. Therefore he could not express his personal views. At the same time, he had every sympathy with Mr. Hall's attempt to provide cheap sanatoriums. He mentioned that a sanatorium was now being erected in Kent by certain friendly societies much on the same lines as the German institutions, at a cost of about £100 per bed. The reason that Germany was provided with so many sanatoriums was on account of the system of compulsory insurance which prevailed there. The building of such institutions was directly encouraged by the insurance societies which found it in their interests to do so. It was not true, though it was generally believed, that consumption was on the increase in this country; as a matter of fact, it had been dying out for the past 50 years. If it decreased at the same rate as it had been doing for the last half century in the course of the next 30 years it would be as rare as leprosy. It was really a question of increasing the rate of decrease. Consumption was largely a social manifestation and as the social condition of the people improved so would tuberculosis fade away.

Dr. T. GLOVER LYON said that too much was made of the questions of sites and accommodation. Provision should be made for more men than women as the number of male patients was double the number of female patients, probably because the woman could not afford to stay away from her home so long as the man. From his experience at the City of London Hospital for Diseases of the Chest patients did better on the balcony system than in the wards of hospitals and in a sense walls were in the way. What was required was a room to sleep in with three sides arranged so that the amount of air flowing through the room could be regulated. If provision was made to shelter the patients from keen east and north-east winds all that was required were four posts and a roof. In these circumstances it seemed remarkable that efforts should be made to build palaces. The size of the room was absolutely a matter of aesthetics and it had nothing whatever to do with treatment. It had a lot to do, however, with the cost. Mr. Hall's plan for building sanatoriums for £85 per bed should be made as widely known as possible.

Mr. FORSYTH said that they were suffering from too much architecture. He referred to an experience at Mount Vernon Hospital, where it was found that patients removed to tents while the extension of the buildings was being proceeded with improved, while those in the hospital lagged behind.

The CHAIRMAN (Mr. NEEDHAM WILSON) said that some provision ought to be made for patients continuing attached to the sanatorium instead of being somewhat prematurely discharged in the interests of more pressing cases. Some sort of a farm colony might be provided.

A vote of thanks to Mr. Hall was then carried with acclamation, to which that gentleman made a brief reply.

MEDICINE AND THE LAW.

The Case of Caleb Charles Whitefoord.

ON March 19th Caleb Charles Whitefoord, formerly a medical man, was convicted at the Central Criminal Court, before the Lord Chief Justice, for using an instrument upon a young woman with intent to procure miscarriage and was sentenced to ten years' penal servitude. He had been sentenced to five years' penal servitude for a similar offence in

1896, and from the information before the court, Lord Alverstone expressed himself as having no doubt that the prisoner, since his release, had carried on his illicit practices among young women for five or six years. His lordship inquired from the detective in charge of the case what the profits of such acts might be and was informed that the price paid to Whitefoord varied from £1 to £10. No doubt to those who have once fallen into the temptation to make money by this particular crime it presents considerable attractions, for although it is carried out with accomplices who are strangers to the principal criminal it is entirely to their interest, as it is to his, to maintain secrecy, and it is to be noticed how often one conviction follows another with criminals of this class. The crime, moreover, is one which lends itself readily to the extortion of blackmail. In the case in question the prisoner put forward his age and bodily infirmities in asking for a lenient sentence but his lordship considered that these were outweighed by the danger of his acts and the misery caused and encouraged by the continuance of such malpractices unchecked.

"At Present in Good Health."

Lawyers have from time to time discussed what is a healthy person, notably in the case of the pregnant and the insane. A recent insurance case, which is reported from the Australian courts, contains a full discussion of this question from the standpoint of the law. On Sept. 14th, 1902, Mrs. Kidman took out a policy of life insurance from the National Mutual Life Association of Australians; one of the conditions was that the would-be holder "is at present in good health." The day after she had been accepted by the office she sent for her medical adviser, with the result that she was examined under an anæsthetic on the 16th and an ovarian tumour was diagnosed. She went at once into a hospital and in the course of a few days the tumour was removed; she died, however, from the effects of the operation on the 28th of the same month. It further appeared that a year previously she had consulted a medical man and had been advised as to the need of a surgical operation before her disorder could be cured. Upon the widower claiming the insurance money the association repudiated the policy as having been obtained owing to false statements. In the first instance the jury decided in favour of Mr. Kidman on the facts of the case as adduced in court. A new trial was moved for and granted and the court again upheld the policy, for it was ruled that the disorder from which the deceased suffered was not one which, except for the unsuccessful operation, was likely to shorten life. Upon appeal to the High Court a broader view was enunciated and judgment was given for the defendants on the ground that the phrase "at present in good health" must be taken to mean that "the person insured was free from any apparent sensible disease or symptom of disease and was unconscious of any derangement of the bodily functions by which health can be tested."

VITAL STATISTICS.

VITAL STATISTICS OF LONDON DURING FEBRUARY, 1907.

In the accompanying table will be found summarised complete statistics relating to sickness and mortality in the City of London and in each of the metropolitan boroughs. With regard to the notified cases of infectious diseases it appears that the number of persons reported to be suffering from one or other of the nine diseases specified in the table was equal to an annual rate of 6.8 per 1000 of the population, estimated at 4,758,218 persons in the middle of the year. In the three preceding months the rates had been 11.1, 9.5, and 6.8 per 1000 respectively. The lowest rates last month were recorded in Kensington, Chelsea, the City of Westminster, Stoke Newington, Holborn, and the City of London; and the highest rates in Paddington, Bethnal Green, Deptford, and Woolwich. The prevalence of scarlet fever showed a slight increase over that recorded in the preceding month; among the various metropolitan boroughs this disease was proportionally most prevalent in Paddington, Hampstead, Shoreditch, Bethnal Green, Greenwich, and Woolwich. The Metropolitan Asylums hospitals contained 2829 scarlet fever patients at the end of last month, against 4003, 3787, and 3116 at the end of the three preceding months; the weekly admissions averaged 323, against 430, 323, and 299 in the three preceding months. Diphtheria showed no appreciable variation in

* Including membranous group.

* Including membranous group.

prevalence from that recorded in January; the notifications of this disease last month were proportionally most numerous in Hackney, Bethnal Green, Battersea, Wandsworth, Deptford, and Woolwich. The number of diphtheria patients under treatment in the Metropolitan Asylums hospitals, which had been 1075, 995, and 921 at the end of the three preceding months, had further declined to 916 at the end of last month; the weekly admissions averaged 126, against 153, 123, and 124 in the three preceding months. The prevalence of enteric fever, which had shown a continued decline during the three preceding months, decreased still further in February; among the various metropolitan boroughs this disease was proportionally most prevalent in Hampstead, Hackney, Southwark, Bermondsey, Battersea, and Woolwich. There were 103 enteric fever patients under treatment in the Metropolitan Asylums hospitals at the end of last month, against 161, 134, and 100 at the end of the three preceding months; the weekly admissions averaged 16, against 24, 18, and 14 in the three preceding months. The greatest proportional prevalence of erysipelas was recorded last month in St. Marylebone, Hackney, Southwark, Camberwell, Deptford, and Greenwich. The 28 cases of puerperal fever notified during the month included six in Lambeth, three in Wandsworth, and two each in Paddington, Islington, Hackney, Southwark, Battersea, and Camberwell.

The mortality statistics in the table relate to the deaths of persons actually belonging to the several boroughs, the deaths occurring in institutions having been distributed among the boroughs in which the deceased persons had previously resided. During the four weeks ending March 2nd the deaths of 6701 persons belonging to London were registered, equal to an annual rate of 18.4 per 1000; in the three preceding months the rates had been 14.7, 18.3, and 19.9 per 1000 respectively. The death-rates last month ranged from 11.7 in Hampstead, 12.2 in Stoke Newington, 14.1 in Chelsea and in Lewisham, 14.9 in Wandsworth, and 15.6 in Fulham, to 22.9 in Bethnal Green, 23.1 in the City of London, 23.3 in Bermondsey, 23.9 in Finsbury, 24.4 in Holborn, and 25.2 in Shoreditch. The 6701 deaths from all causes in London last month included 466 which were referred to the principal infectious diseases; of these, 130 resulted from measles, 28 from scarlet fever, 72 from diphtheria, 164 from whooping-cough, 10 from enteric fever, and 62 from diarrhoea, but not any from small-pox, from typhus, or from ill-defined pyrexia. No death from any of these diseases was recorded last month in the City of London; among the metropolitan boroughs they caused the lowest death-rates in Chelsea, St. Marylebone, Hampstead, St. Pancras, and Stoke Newington; and the highest rates in Shoreditch, Bethnal Green, Bermondsey, Deptford, and Woolwich. The 120 deaths from measles were 50 below the average number in the corresponding periods of the five preceding years; among the various metropolitan boroughs this disease was proportionally most fatal in Shoreditch, Bethnal Green, Stepney, Bermondsey, Deptford, Greenwich, and Woolwich. The 28 fatal cases of scarlet fever showed a decline of ten from the corrected average number; the greatest proportional mortality from this disease occurred in Paddington, Hammersmith, Shoreditch, Bermondsey, and Woolwich. The 72 deaths from diphtheria were 11 fewer than the average; the highest death-rates from this disease last month were recorded in Hackney, Holborn, Finsbury, Stepney, Deptford, and Greenwich. The 164 fatal cases of whooping-cough were slightly below the average number in the corresponding periods of the five preceding years; among the various metropolitan boroughs this disease was proportionally most fatal in Paddington, Bethnal Green, Southwark, Bermondsey, and Camberwell. The ten deaths from "fever" were less than half the corrected average number; of these ten deaths two belonged to Hackney, two to Stepney, two to Lambeth, and one each to Fulham, Hampstead, Islington, and Battersea. The 62 fatal cases of diarrhoea were equal to the average number in the corresponding periods of the five preceding years; this disease showed the greatest proportional mortality in Fulham, the City of Westminster, Hackney, Holborn, Bethnal Green, and Wandsworth. In conclusion, it may be stated that the aggregate mortality from the principal infectious diseases in London last month was nearly 24 per cent. below the average.

Infant mortality, measured by the proportion of deaths under one year of age to registered births, was equal to 127 per 1000. The lowest rates of infant mortality were

recorded in Chelsea, Stoke Newington, Holborn, Stepney, and Greenwich; and the highest rates in Kensington, the City of London, Shoreditch, Bermondsey, and Woolwich.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointments are notified:—Fleet Surgeons: A. L. Christie to the *Hawke*, E. O. Ward to the *Barfleur*, J. Jenkins to the *Hood*, J. O. Ferguson to the *Ariadne*, and J. O. Wood to the *Andromeda*. Staff Surgeons: W. L. Martin to the *Ganges*, for Shotley Barracks; A. W. B. Livesay to the *Bonaventure* on commissioning; J. W. Craig to the *Hawke*, R. S. Burniston to the *Cumberland*, A. H. Jeremy to the *Carnarvon*, and J. Martin to the Royal Marine Depot, Deal. Surgeons: L. Lindop to the *President*, for three months' study at West London Hospital; F. M. V. Smith to the *Cumberland*; H. A. Browning to the *Pembroke*, additional, lent to *Triton* for surveying season; A. F. Fraser to the *Donegal*, F. E. Bolton to the *Barfleur*, H. G. T. Major to the *Hood*, E. S. Wilkinson to the *Achilles* on commissioning, and R. W. G. Stewart on commissioning.

ROYAL ARMY MEDICAL CORPS.

The undermentioned Lieutenants to be captains (dated Feb. 28th, 1907):—Arthur C. H. Gray, Douglas P. Watson, Thomas S. Dudding, John E. Powell, Francis M. M. Ommanney, Osburne Ievers, Robert H. MacNicol, Hugh H. J. Fawcett, Santiago L. Pallant, Charles R. Sylvester-Bradley, Stanley E. Lewis, Gerard A. Kempthorne, James T. McEntire, Norman E. Dunkerton, Patrick J. Hanafin, John D. Richmond, Ernest M. Glanville, Marmaduke O. Wetherell, Harold C. Hildreth, William MacD. MacDowall, Reginald T. Collins, Thomas J. Wright, and Arthur C. Osburn.

ROYAL ARMY MEDICAL CORPS IN INDIA.

Lieutenant-Colonel L. T. M. Nash is appointed to command Station Hospital, Barrackpore, vice Lieutenant-Colonel J. B. Buchanan; Major F. Smith, D.S.O., to command Station Hospital, Benares, vice Major H. P. Johnson; Lieutenant-Colonel M. W. O'Keefe is appointed officer commanding Station Hospital, Karachi; Lieutenant-Colonel S. Westcott is appointed officer commanding Station Hospital, Mhow; Lieutenant-Colonel J. R. Stuart is appointed officer commanding Station Hospital, Neemuch; Lieutenant-Colonel G. E. Hale is appointed officer commanding Station Hospital, Hyderabad; Lieutenant-Colonel C. T. Blackwell is appointed officer commanding Station Hospital, Belgium; and Lieutenant-Colonel A. Kennedy is appointed officer commanding Station Hospital, Pachmarhi. Captain H. A. Davidson has arrived at Bombay. Lieutenant-Colonel J. Battersby, Major T. H. J. C. Goodwin, D.S.O., and Captain D. Curme have embarked for England. Captain R. H. Bridges has been granted leave out of India for six months on medical certificate. The following officers have been granted extension of sick leave: Lieutenant-Colonel H. Cocks to May 11th and Captain T. Biggam to May 17th, 1907. Lieutenant-Colonel M. W. O'Keefe has been posted to the 4th (Quetta) Division; Lieutenant-Colonel S. Westcott to the 5th (Mhow) Division; Captain J. S. Galle to the 6th (Poona) Division; Captain E. W. Powell to the 6th (Poona) Division; and Lieutenant M. J. Cromie to the 5th (Mhow) Division. Lieutenant-Colonel C. T. Blackwell has been transferred from the 4th (Quetta) Division to the 6th (Poona) Division; Lieutenant-Colonel A. Kennedy from the 6th (Poona) Division to the 5th (Mhow) Division; Lieutenant-Colonel J. J. O'Donnell from the 5th (Mhow) Division to the 6th (Poona) Division; Lieutenant-Colonel F. R. Newland from the 6th (Poona) Division to the 5th (Mhow) Division; Major R. C. Thacker from the Aden Brigade to the 4th (Quetta) Division; Major F. G. Faichnie from the 5th (Mhow) Division to the Aden Brigade; Captain T. Biggam from the Aden Brigade to the 6th (Poona) Division; Captain M. F. Foulds from the 6th (Poona) Division to the Aden Brigade; and Lieutenant F. J. Turner from the Aden Brigade to the 4th (Quetta) Division.

VOLUNTEER CORPS.

Royal Garrison Artillery (Volunteers): 1st Cinque Ports: Surgeon-Lieutenant J. W. Harrison resigns his commission (dated Jan. 1st, 1907).

Rifle: 1st Volunteer Battalion the East Lancashire Regiment: Howard Henry to be Surgeon-Lieutenant (dated

Jan. 21st, 1907). 4th Volunteer Battalion the Durham Light Infantry: The undermentioned to be Second Lieutenant: Ernest George Dryden Benson (late Surgeon-Lieutenant) (dated Jan. 15th, 1907).

ROYAL ARMY MEDICAL CORPS (VOLUNTEERS).

London District: London Companies: Harold Arthur Thomas Fairbank to be Lieutenant (dated March 1st, 1907).

INDIAN MEDICAL ARRANGEMENTS.

The *Standard* of March 25th states that "Lord Kitchener has decided to reorganise the paid appointments to staff surgeons and hospitals among officers of the Royal Army Medical Corps and those of the Indian Medical Service. The establishments will be altered to secure better coördination and working, especially in the north, and the new allotment comes into force on Monday next."

THE NEW ARMY SCHEME.

Mr. Haldane is indefatigable in his endeavours to render his new schemes for the creation of a really national army a success. For this purpose he knows a territorial army to be absolutely essential and that everything turns upon the willingness of the nation to provide it. The question yet to be answered experimentally is whether the number of men required will be forthcoming. The subject has a hygienic and physical health side to it of a very important kind upon which we have previously commented. Mr. Haldane concluded his recent speech at the Guildhall, when he distributed the prizes to a cadet battalion of the King's Royal Rifle Corps, by taking up a position for which we have always contended. "Could anyone look upon a first-rate cadet corps without feeling that every young man in it was better and stronger morally and mentally for the discipline to which he had voluntarily subjected himself? It helped him in life, it helped him in his employment; it helped him to be a better citizen, and fitted him not only for military but civilian duties. From every point of view the cadet corps was a thing to be encouraged in the interests of the nation."

Correspondence.

"Audi alteram partem."

SLEEPING SICKNESS ON THE LUALABA RIVER, CENTRAL AFRICA.

To the Editors of THE LANCET.

SIRS,—Early in the year 1905 Dr. Dutton and Dr. Todd visited the Upper Congo as far as 6° S. Lat. In their valuable report¹ they give Bull as the most southern point of infection on the Upper Congo. Bull is on the Lualaba river, 60 miles south of Kasongo and about 5° 30' S. Lat. Some native porters from Lake Kasali, 200 miles farther south, were examined but no indications of sleeping sickness were evinced. It was supposed, therefore, that the disease at that time had not extended farther south on the Lualaba than Bull.

In August of last year I received a communication from Mr. J. H. Hayes, who was travelling from Lake Kasali southward for 100 miles, stating that the Baluba people in the villages along the Lualaba appeared to be dying in increased numbers and from a disease quite unknown to the people themselves. He believed that it might be sleeping sickness as some of them evinced those symptoms. In October I proceeded to this district on a tour of investigation. At Wundwi, which is a short distance below the Kalenge Rapids on the Lualaba River, and about 100 miles south of Lake Kasali, I found by microscopic examination of cervical gland fluid that 70 per cent. of those examined were infected with trypanosomes. Adults and children alike were infected. The women and children were probably more commonly infected than the men. The old people seemed to be more or less free. These proportions as to age applied to all the villages visited.

At the Congo Post of Bukama, of 45 soldiers from all parts of the Congo State, ten were shown to harbour the organisms in their cervical glands. Of 20 workers from the surrounding district five were infected. At Tengalonzi, opposite the

Post, of 50 examined 40 showed unmistakable glands by palpation and eight had enlarged glands but not so characteristic. At Pengi 30 out of 50 were found with enlarged glands. At Lambula 25 out of 35 were with enlarged cervical glands. At Karu on Lake Kavele, 15 miles west of the Lualaba, I found 20 per cent. of the people with typical glands. The examination of 129 carriers from Lake Kasali showed 11 per cent. to be infected.

The conclusion to be drawn from these observations is that the district is heavily infected. After removing all apparent sources of error it appears on a conservative estimate that at least between 40 and 50 per cent. of the inhabitants have trypanosomiasis. This represents a slightly heavier infection than Dr. Dutton and Dr. Todd found in the districts 200 miles north of this. As before mentioned, the natives themselves recognise sleeping sickness as a new disease. It was also noted above that Dr. Todd had examined at Cabinda two years ago a number of porters from Lake Kasali, but he failed to find in them any indication of trypanosomiasis. It seems, therefore, probable that the disease was not introduced earlier than three years ago at the longest. Dr. Todd mentions that the disease was first noticed at Cabinda in 1900. The mode of introduction seems evident. The Lake Kasali people have for some years carried on an extensive trade in dried fish with Cabinda, 200 miles north. They catch the fish, dry it, and carry it to Cabinda, where they find a ready sale. These carriers have contracted the disease at Cabinda and have been the means of infection on Lake Kasali and the River Lualaba to the south. That it has been introduced in any other way seems improbable, as the Kasali people do not visit any other possible source of infection.

This is the first year that the natives have noticed an increased mortality in their villages. Moreover, they have observed that this increase is only in the villages along the river. Hence, quite on their own initiative they are beginning to move their villages to locations inland. The southern limit of the disease at present seems to be the Kalenge Rapids, about 9° 15' S. Lat. That the disease has not already spread farther south is no doubt due to the fact that the people below the Rapids have practically no intercourse with those above.

The glossina palpalis.—The fly was noticed all along the river where the disease was prevalent. It has also been found at the following places which are as yet free from infection. At the junction of Lufupa and Lualaba rivers; on the Mukulezhi river at about 10° 40' S. Lat.; on the west side of Lake Mweru; at the junction of the Dikulwe with the Lufira river; on the South Kaluli river; on the Luapula river, 10° 29' S. Lat. (Mr. Arthur Pearson); and on the Fwalendes river. Active measures are being taken to prevent the spread of the disease southward. Posts of inspection are established on the main trade routes and it is believed that much can be done to stay its progress. At least its advance can be much delayed, possibly until such time as a cure may be discovered.

I am, Sirs, yours faithfully,
A. YALE MASSEY, B.A., M.D. Tor.,
Medical Officer, Tanganyika Concessions, Limited,
Central Africa.

Ruwe, Congo Free State, Jan. 22nd, 1907.

ALBINISM IN MAN.

To the Editors of THE LANCET.

SIRS,—On looking into the various hereditary conditions which affect man for one which would lend itself to the application of Mendelian methods of investigation that of albinism appealed to me as the most suitable for my purposes. The condition is a striking one, such as may reasonably be expected to impress even the most casual observer, and its occurrence at any time in a family would be a circumstance not likely to be soon forgotten. No estimate that I know of has yet been made as to the frequency with which it occurs in the general population, but it is at least sufficiently common to provide satisfactory data for work such as this.

The condition in itself does not call for description for purposes of identification, but when dealing with a subject about which so little is known it may be as well to venture on a description of what I take to be the type. In the first place, then, in the typical human albino the skin is of a uniform milky colour, except in those parts where the epidermis is thin, allowing the vessels underneath to show through in a highly characteristic manner. The hair system

¹ *Memor. xviii.*, the Liverpool School of Tropical Medicine, March, 1906.

vehicles, such as furniture vans, very often carry a small light in front placed in such a position that vehicles overtaking them have no warning until they are close on them. The country doctor using his motor in answer to an urgent summons in the night or early hours of the morning runs in constant danger from this cause, and every one of us must at some time or other have had narrow escapes owing to the absence of a light showing to the rear giving warning of a cart in front. Even before it was necessary that the motor-cars should carry a light at the back for the purpose of illuminating the number plate it was compulsory that they should show a red light at the back, and how it could be possible for legislators to pass a Bill compelling the fastest vehicles on the road to show a light at the back to prevent them being run into and yet allow farm carts and furniture vans and the like to use the same road and yet carry no light at the back at all has always been a puzzle to me. It would be a great help in securing such an amendment as I have referred to if all medical motorists in the country would write to the Member of Parliament for their district pointing out the danger run by the doctor who has to be out at all hours of the night. I hope medical men will not treat this matter as though it were one of little concern to themselves. The passing of such an amendment would amply repay every medical man in the country for the small amount of time it would take to pen such a letter.

I am, Sirs, yours faithfully,

H. E. B. BRUCE-PORTER,

Honorary Secretary, Committee of Medical Men using Motors.

Grosvenor-street, W., March 22nd, 1907.

"A DESCENDANT OF HUGH OLDHAM."

To the Editors of THE LANCET.

SIRS,—In referring in your issue of March 16th, p. 765, to the late Mr. O. J. Oldham, F.R.C.S., as a "descendant" of Hugh Oldham, Bishop of Exeter, you are exposing that prelate's memory to a good deal of obloquy. The vow of celibacy was enjoined on the clergy by Pope Hildebrand in or about A.D. 1000, whereas Hugh was not born before 1450 and died in 1520. That he died excommunicate is true, but this was not for a breach of the Papal decree but for a dispute on a building question with the powerful Abbot of Tavistock.

The late Mr. Oldham did not claim to be a descendant, but a "kinsman," of Bishop Hugh; beyond that, if we are to judge by his bequests, he seems to have known little about him. For, though Hugh founded Manchester Grammar School, he was also founder of Netley Abbey, which the will ignores. Again, he founded Corpus Christi College, Oxford, in conjunction with Stephen Fox, Bishop of Winchester; but he was also, with the Bishop of Lincoln, joint founder of Brazenose College, Oxford, which is also ignored. As a matter of fact, no Oldham within the last 200 years ever has been able to prove direct connexion either with Bishop Hugh or with Bishop Richard Oldham, who in the thirteenth century was Abbot of Chester and Bishop of Sodor and Man.

I am, Sirs, yours faithfully,

RALPH S. OLDHAM.

* * Our Manchester Correspondent was in error in using the word "descendant."—ED. L.

TERTIARY SYPHILITIC FEVER.

To the Editors of THE LANCET.

SIRS,—Dr. F. Parkes Weber has done well to draw attention to the occurrence of fever with syphilitic lesions, but I venture to suggest that he has not paid sufficient attention to the main points at issue. It may be true that many syphilitic lesions are accompanied by a varying degree of pyrexia—probably more often than is suspected—owing to the fact that the temperature is rarely taken for any considerable time in cases of syphilis. But this is a point of comparatively slight importance from the clinical point of view.

The importance of *syphilitic fever* (I omit the word "tertiary" because there is no real pathological distinction either in time or nature between the so-called secondary and tertiary lesions) consists mainly in the diagnosis. Fever due to syphilis has been mistaken for typhoid fever, pneumonia, and tuberculous meningitis. Dr. J. D. Rolleston has recently

drawn attention to this question with regard to typhoid fever. He has also reported a case in which early syphilitic brain symptoms were mistaken for enteric fever.

Fournier divides syphilitic fever into symptomatic and essential, the former accompanying the outbreak of cutaneous eruptions, &c., the latter independently of them. It is to the latter class that Dr. Parkes Weber refers. Fournier describes a continuous type and an intermittent type, the former of which he designates syphilitic typhosis (typhosis). He also points out that such cases of "syphilitic typhosis" may be mistaken for enteric fever, and says that the chief points in which syphilitic typhosis differs from enteric fever are the absence of the characteristic temperature chart of enteric fever, the enlarged spleen, iliac pain, dry, glazed tongue, and delirium. The blood is also negative to Widal's agglutination reaction. It would therefore appear that, however interesting "syphilitic fever" may be from a pathological point of view, its main importance lies in its diagnosis from enteric fever, meningitis, and pneumonia.

I am, Sirs, yours faithfully,

C. F. MARSHALL.

New Cavendish-street, W., March 18th, 1907.

To the Editors of THE LANCET.

SIRS,—It does not appear to be generally known that the occurrence of fever in syphilis was mentioned by some of the earliest writers on the disease. Having recently had occasion to peruse the early literature of syphilis I have thought that the following notes might be of interest to some of your readers. Long before John Hunter,¹ to whom Dr. Parkes Weber alludes in his interesting paper,² the syphilographers of the sixteenth century, whose works are contained in the collection of Lullinus, had spoken of the existence of fever in the *Morbus Gallicus*. According to Fracastor,³ to whom syphilis owes its name, a slight degree of fever was an occasional though rare event: "*Quandoque et febricula quedam concomitabatur, sed raro.*"⁴ Fallopius's words are similar:⁵ "*Solet aliquando febricula adungi ob fervorem circa viscera ferventia. Sed hoc raro fit.*" Petronius wrote to the same effect:⁶ "*His nunc aberat, nunc adjuncta febris erat.*" Haschard⁷ also speaks of a "*lenis febricula*" as one of the early symptoms of the disease. Rondelet,⁸ the original of Rabelais's *Rondibilis*, stated that "some after receiving the infection are seized with fevers and falling into profuse sweats part of the venom is discharged thereby."⁹

According to Vigo,⁹ fever was a late symptom. "*Ultimo loco vidimus febriculam oriri quæ tot prænominatis malis hominem ad ultimum ejus diem conducebat.*" Ulrich von Hutten,¹⁰ one of the most interesting figures in the history of the Reformation, and himself a sufferer from the new disease, also stated that "phthisis" was a sequel. Ambroise Paré¹¹ also reckoned fever among the late phenomena: "*Autres demeurent asthmatiques et hectiques avec une fièvre lente, et meurent tabides et desseichez.*" Brassavolus¹² took a less serious view of protracted fever: "*Lente febris, ac longæ cum morbo Gallico futuram heclicam minime significant. Infinitos enim vidi, qui in tales incidere febres ... tamen heclicæ non evasere, imo Gallico affectu curato, et etiam per existentia, febris ipsa una curata est, ac abiit.*" Of subsequent writers prior to John Hunter, Daniel Turner deserves special mention. In his work on syphilis which seems to have fallen into ill-merited oblivion numerous references are made to the existence of fever in syphilis.¹³ Then, as now, patients supposed to be suffering with phthisis were really the subjects of venereal infection, and when almost reduced to the last extremity owed their salvation to a correct diagnosis and the exhibition of mercury.

How hopeful a view Turner took of syphilitic fever is well shown by the following quotation: "*Of all the several sorts of consumptions I should more willingly encounter the*

several than any of the rest, where the Blatterpox especially had been overlooked and the Body before unacquainted with the antidote, I mean any mercurial preparation . . . Where one Pox is carried off by a pocky Heetick . . . we have twenty, I might say forty, melted down or dry'd away by that of another nature." "The celebrated Astruc," Turner's contemporary, noted "intermitting and slow fevers among the Disorders of the general Functions in Pocky Persons. . . . slow fevers most commonly arise from violent Pains, from Ulcers of various Parts, from Gummata, from the Putrefaction of Nodes or Exostoses, from Internal Abscesses, &c.; all of which constantly happen in an Intermitting Pox." Of writers later than John Hunter but prior to Wunderlich, Swediaur¹⁴ and Bazzerac¹⁵ in France and Erasmus Wilson¹⁶ in this country should be mentioned. Swediaur states that a kind of slow fever with a weak and accelerated pulse often precedes the appearance of ulcers in the throat and the cutaneous eruption. He also deals with syphilitic phthisis, in which he says the maculation is generally unaccompanied by fever, but hectic fever is sometimes present. Bazzerac had frequently seen febrile attacks in the syphilitic closely resembling a double tertian.

Whether the early writers were correct in attributing fever in each case to syphilis is a matter now impossible to decide. Forster¹⁷, though justly appreciative of their work, admits that they were often unduly credulous and attributed certain morbid states to venereal infection on most inadequate and perilous grounds. Enough, however, has been said to show that the occurrence of fever in syphilis, both at an early and late stage of the disease, and the resemblance of the fever to that of tuberculosis or malaria were recognised long before the introduction of the clinical thermometer.

J. D. HOLLISTON.

Grove Fever Hospital, B.W., March 15th, 1897.

THE DETECTION OF ACETONE IN THE URINE.

To the Editors of THE LANCET.

SIRs,—A ring test, essentially the same as that described in THE LANCET of March 23rd, 1907, p. 206, and on which you comment with approval in an annotation on p. 324 of the same issue, was published by Von F. Lange in the *Münchener Medizinische Wochenschrift*, No. 28, 1906. In Lange's method 15 cubic centimetres of the urine to be tested are mixed with 0.5 to 1.0 cubic centimetre of glacial acetic acid and a drop of freshly prepared sodium-chlorophyll solution. A cubic centimetre of strong ammonia is then run on to the surface and in the presence of acetone a more or less intense violet ring appears at the line of contact, the depth of the colour and the width of the ring varying with the quantity of acetone present in the urine. By this method it is said that 100 per cent. of acetone can be detected, and it has certainly proved in my hands a most delicate and reliable test.

I am, Sirs, yours faithfully,

BAUNSLAND, W., March 22nd, 1907. P. J. CAMMERMEYER.

CENTRES OF MORAL INFECTION.

To the Editors of THE LANCET.

SIRs,—From time to time I, and I have no doubt you, Sirs, and other readers are called at the filthyness of writings and writings in the old-fashioned public consciousness form. I write with, fresh in my mind, a horrible—shall I term it "Grimace"—which I have just seen, and which everybody seeing the place had to see, in a convenience near the corner of the Kensington Gardens. This is a place which must be constantly visited by boys and girls playing in the park. It is impossible to overstate the harm which may be done to them by such places. Now, the London County Council has proposed that at centres of traffic are gradually reducing them. I have seen a place in London place a number, and it is really to be hoped, for the moral state of the people, that they may be removed. At this

but they are abominations. At the present time a new convenience is, I believe, being provided in the Bayswater-road a couple of hundred yards to the east of the filthy place which I have more specially indicated, and it is greatly to be hoped that if M. Park Commissioners will at the earliest moment abolish the old iron filth discriminator and plant decent grass on its site.

I am, Sirs, yours faithfully,

A MEMBER OF TWO HOSPITAL COMMITTEES.

London, March 21st, 1907.

THE ORGANISATION OF THE MEDICAL PROFESSION IN FRANCE.

(FROM OUR SPECIAL CORRESPONDENT.)

The Twenty-fifth Anniversary of the First French Medical Union.—8000 out of 20,000 Medical Men in Salon.—The Parliamentary Medical Group.—220,000 lived in Paris Alone.

Paris, March 15th.

THE medical unions of France have now been in existence over a quarter of a century. Last year a festival was held to celebrate what was called the "silver wedding" of the union of medical men. Strange to say, this movement did not originate in Paris or one of the great provincial centres, but on the contrary in one of the most reactionary and least enlightened parts of France—namely, La Vendée. It is true that so far back as the year 1879 a medical practitioner of Marre, Dr. Marguerite, wrote to the late Dr. Auguste Gailly, who had just founded the *Concours Médical*, protesting that barristers, solicitors, and others were forming unions to defend their professional interests, but that medical men remained listless and disorganised. This letter was the beginning of a prolonged discussion. Many different opinions were expressed and several medical men wrote in opposition, saying that a medical union, if formed, would soon become the instrument of some outside or party and would promote the interests of a selected group to the disadvantage of all the other practitioners. At last the *Concours Médical* appointed a special committee to investigate the whole question. While these debates and discussions were proceeding, in the far-off country district of the Vendée a few practical men actually did what others were merely talking about. It was on March 6th, 1881, that the rules of the Medical Syndicate of Montaigu were definitely adopted and thus the first union of French medical men came into existence. On May 16th following this syndicate held its first official meeting.

Montaigu is a little town of only about 1200 inhabitants and is situated on the banks of the Maine, which is an affluent of the *Loire-Inférieure* in the *Bocage Vendéen*. This town, though small, has a history. It was strongly fortified by Louis XI. It has often been besieged and sacked in turn by the Protestant and by the Roman Catholic armies during the wars of religion. Then more recently it was again taken and retaken by the Republicans and the Royalists during the insurrection of the Vendée. Now there remain but a portion of the dungeon and deep trenches where the walls overlooked the moat. Yet the fighting instinct of the place is not extinct. There is no longer war between rival creeds or rival political systems, but here medical men were first impelled to undertake an economic war in defence of the professional dignity and their material well-being. Dr. Gustave Migon was their leader and he continued to gather together in this small place no less than 40 practitioners, some of them coming from the neighbouring department of the *Loire-Inférieure*. Dr. Migon was born in this little place on Dec. 25th, 1842, and belongs to a well-known family of La Vendée. He received his medical education at Nantes and at Paris, terminating his studies in 1873. He at once went to practice in his native town. Before the great Revolution the Faculty of Medicine was a very close corporation, of very jealous disposition, and not well disposed towards innovations; but all forms of monopoly were swept away by the Revolution. The Empire reorganised the schools of medicine, though it was as opposed to the formation of unions among medical men as it was to all forms of independence or individuality. Therefore, when Dr. Migon began to practice he found the medical profession in a very unattractive condition. There was no rule of conduct, no uniform within the ranks of the profession, everyone was for himself "and the devil

Having recently¹ had occasion to peruse the early literature of syphilis I have thought that the following notes might be of interest to some of your readers. Long before John Hunter,² to whom Dr. Parkes Weber alludes in his interesting paper,³ the syphilographers of the sixteenth century, whose works are contained in the collection of Luisinus, had spoken of the existence of fever in the Morbus Gallions. According to Fracastor,⁴ to whom syphilis owes its name, a slight degree of fever was an occasional though rare event: "Quandoque et febricula quedam concomitabatur, sed raro." Fallopius's words are similar:⁵ "Solet aliquando febricula adungi ob fervorem circa viscera fermentia. Sed hoc raro fit." Petronius wrote to the same effect:⁶ "His nunc aberat, nunc adjuncta febris erat." Haschard⁷ also speaks of a "lenis febricula" as one of the early symptoms of the disease. Rondelet,⁸ the original of Rabelais's Rondibilis, stated that "some after receiving the infection are seized with fevers and falling into profuse sweats part of the venom is discharged thereby."⁹

According to Vigo,¹⁰ fever was a late symptom. "Ultimo loco vidimus febriculam oriri que tot pronomatis malis hominem ad ultimum ejus diem conducebat." Ulrich von Hutten,¹¹ one of the most interesting figures in the history of the Reformation, and himself a sufferer from the new disease, also stated that "phthisis" was a sequel. Ambroise Paré¹² also reckoned fever among the late phenomena: "Autres demeurent asthmatiques et hecticques avec une fièvre lente, et meurent tabides et desséchés." Brassavolus¹³ took a less serious view of protracted fever: "Lentæ febres, ac longæ cum morbo Gallico futuram hecticam minime significant. Infinitos enim vidi, qui in tales incidere febres etiam tamen hectici non evasere, imo Gallico affectu curato, et etiam per existentia, febris ipsa una curata est, ac abivit." Of subsequent writers prior to John Hunter, Daniel Turner deserves special mention. In his work on syphilis which seems to have fallen into ill-merited oblivion numerous references are made to the existence of fever in syphilis.¹⁴ Then, as now, patients supposed to be suffering with phthisis were really the subjects of venereal infection, and when almost reduced to the last extremity owed their salvation to a correct diagnosis and the exhibition of mercury.

How hopeful a view Turner took of syphilitic fever is well shown by the following quotation: "Of all the several sorts of consumptions I should more willingly encounter the

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

Cost of Pauper Lunatics.

WHETHER the apparent increase of insanity be real or the result of increased publicity and greater care for the safety and comfort of the insane there is no doubt as to the serious increase of cost under which the ratepayers are beginning to groan. The deputation on March 10th to the Home Secretary from the Lancashire asylums boards and boards of guardians in the county of Lancaster on the subject of the provision for pauper lunatics was perfectly justified, though no immediate results seem likely to appear. All are agreed that during the last 20 years the expenditure has largely increased, while there seems to be no proportionate increase of cures. And it will be agreed by those who consider the real requirements of the majority of the cases of chronic insanity, that although their surroundings should be airy, bright, and cheerful, several members of the deputation were right in urging that they thought that less costly buildings and less costly maintenance might suffice for chronic cases. No doubt several influences have been at work in causing what may be called extravagance in the building and arrangements of some of our pauper asylums. One of these is the very common one that those who are responsible consider that they should have a structure worthy of the conspicuous position usually occupied by asylums. This has often been illustrated in Manchester in the public buildings erected by the corporation, very notably in some of the palatial baths that were to be "worthy of the city." But why the evidence of so much insanity in our midst should be blazoned forth in this way is not very clear to the sane mind. Then, too, as is quite natural, architects, ambitious, of course, of erecting something that will strike the public eye, may often unconsciously, and sometimes perhaps even consciously, lead authorities into expenditure not really required. The chief necessities are air, light, and good ventilation, which can be provided without elaborate decoration, and good design as to form need not be specially expensive. The Home Secretary evidently sympathised with the deputation in the desire for economy and it is to be hoped that efforts in that direction will be more successful in the future than they have been in the past.

Dangers of Drinking in the Dark.

A pitiful case of accidental poisoning took place at Blackburn on March 20th. A wholesale druggist was cleaning some silver ware in a small conservatory connected with the scullery with cyanide of potassium, which he had in a teacup. He went out to find a silver matchbox to clean, leaving the cup containing the poison on the table, and turning down the light in the scullery, which was the only one that gave light in the conservatory. During his absence his wife went into the scullery to take some pills. She picked up the cup and did not notice anything in it as the place was dark. She drew water from the tap, took a drink from the cup, and then ran into the sitting room calling to her husband, "There is something in that cup," and died almost immediately, before a medical man who was next door could get to her. It is not of much use, perhaps, to moralise on the dangers surrounding those of us who deal in this careless, irresponsible fashion with deadly weapons of any kind, and yet it does not seem right to pass such cases by in silence. The whole history of the case shows a want of appreciation of the danger of leaving a deadly poison in a dark or very dimly lighted room that is almost incredible, and the drinking of this poor woman's fatal draught from a cup which she could only see imperfectly is almost equally incomprehensible. The story points its own moral and, as the coroner said, shows "how very careful people should be when using any sort of deadly poison."

Death from Potomane Poisoning.

One of those unfortunate cases of ptomaine poisoning was inquired into by the Manchester city coroner about a fortnight since. In this case the fatal result was due to eating tinned salmon. Five members of the family and a friend had some of the salmon, which had been bought on the same day. Four of them were taken ill and one little girl died after a week's illness. The shopkeeper said that the salmon had been in stock for three months, which was not considered a long time. They might be kept for years and still be all

right. So many of these cases occur, and the difficulty of discovering whether the contents of the tin that is opened will serve as wholesome food or be the messenger of death should surely be reason enough to incite the men of science to further and closer investigation, so that if possible the unscientific person may be able to detect the dangers of tinned meat before it is too late.

Death from Anthrax.

An inquest was concluded in Salford on March 19th as to the death of a seaman at the Salford Royal Hospital. Mr. W. F. Dearden of the port sanitary authority and Professor S. Delépine found anthrax bacilli in the body. The man was employed on a vessel which carried cattle and during the voyage one of the beasts died and he helped to throw the carcass overboard. The supposition is that he went immediately and shaved himself (it was on a Sunday morning) without washing his hands. In that way, if the animal suffered from anthrax, the germs might easily be conveyed to his own body.

Accrington Hospital Extension.

Accrington has decided to add a new block to the Accrington and District Victoria Hospital. It is to cost £10,000, towards which sum £3000 or more have already been promised. The need for extension is said to be pressing, for the hospital is increasingly useful and the demands on its services continue to grow.

Waste of Infant Life.

At an inquest held about a fortnight since at Blackburn on a baby six months old the mother said she had three children living and had lost seven by death. Only one had lived to be six years old, the others ranged from six months old to a year and three months. The verdict was "death from natural causes, accelerated by neglect in not calling in a medical attendant." The foreman of the jury thought that parents in such cases ought to be seriously dealt with. "It was ridiculous that a child of that age should weigh only five pounds five ounces." It is not wonderful that so many children die, the marvel is that so many live.

Meat Inspection.

Even if the very active trade carried on by the "slink butchers" is put aside there is good reason for a careful inspection of meat. The Manchester corporation, therefore, must be commended for appointing two young veterinary surgeons as meat inspectors. The salary in each case is £150 a year.

March 28th.

LEEDS.

(FROM OUR OWN CORRESPONDENT.)

The General Infirmary at Leeds.

UNDER the chairmanship of the treasurer, Mr. Charles Lupton, the 139th annual meeting of the supporters of the largest of the Leeds charities was held on March 21st. In this column on Jan. 26th an abstract was given of the statistics for the year 1906, the period covered by the annual report, which was taken as read at the meeting. Commenting on the increase of work in all departments of the infirmary, the treasurer directed particular attention to the increase in the amount of abdominal surgery done during the last 20 years. In 1852 there were only 25 abdominal sections performed, and of these ten resulted in the death of the patient. In 1905 there were 504 operations of the class performed; of these, 398 were successful, in 17 cases the patients were unrelieved, and death occurred in 89 instances. The mortality had thus decreased from 40 to less than 18 per cent. The statistics of abdominal cases for 1906 had not been worked out, but the number of abdominal sections had increased by 60. Mr. Lupton in the course of his remarks made an interesting reference to the development of open-air treatment, the utility of which had been emphasised in the management of cases of tuberculosis, pointing out that it was now largely employed in the treatment of many more cases of a non-tuberculous character than formerly. This was especially carried out at the semi-convalescent hospitals at Cookridge and during last summer there were seldom fewer than 20 men, women, and children living day and night entirely out of doors, while even in winter there had been 10 or 12 living with great benefit under the same conditions. Even at the infirmary the outdoor treatment was

take the hindmost." Under the Empire the State always feared the coming into existence of any organisation that might dispute its absolute authority. The most that could be attempted was the formation of a few benefit or mutual insurance societies. However, the Empire fell in 1870, and as the French nation began to recover from the disasters of the war a new and more independent spirit developed under the Third Republic. No sooner had Dr. Mignen formed this union between his neighbouring 40 rural practitioners than the spirit of rivalry between them died away. Instead of competing they helped each other. They agreed on a uniform tariff in regard to their fees and determined not to allow themselves to be exploited by benefit societies or by insurance companies. Soon the example spread. A medical union was formed at Pouzanges, then at Challanges and other places, and after a while all these local unions united and constituted the formidable Syndicate of the Medical Practitioners of the Department of the Vendée.

From the very beginning, however, Dr. Mignen understood that in a country like France, where everything is centralised, mere local effort would not suffice. Therefore he communicated with the *Concours Médical* and was appointed on a committee, with Dr. Barat-Dulaurier of the Dordogne, Dr. Margueritte of Havre and Dr. E. Noir of Brioude, who were now all striving to form medical unions in their respective localities. This was the nucleus which, after the enactment of the law of 1884 authorising the creation of professional and trade unions, advocated, and finally brought into existence the Union of the Medical Syndicates of France. To-day this federation of local unions consists of 80 different syndicates, having about 5500 members. But there are, all included, 157 medical unions with about 8000 members, only many of them are not affiliated to the central union or federation. According to the last published estimate there are 3815 medical men in Paris and 15,189 in the departments. Then there are 470 practitioners in Algeria and 105 in the other colonies, in all 19 579 medical men, and there are also 985 *officiers de santé*, a lower form of qualification which is no longer accorded. Thus, in round numbers, it may be said that there are 20,000 medical practitioners and that 8000 of them are in union. This is a very high proportion and speaks well for the spirit of organisation of the French members of the profession. The income of the national federation is more than sufficient, amounting to nearly £1000 per annum and last year it was able to invest £152. Such is the present position of affairs as shown by figures, and to celebrate this success a gathering and a banquet took place at Montaigu on May 16th, the twenty-fifth anniversary of the commencement of the movement. From all parts of France medical men came, as it were, on a pilgrimage, to visit the cradle of their medical unions and to render personal homage to Dr. Gustave Mignen and the premier medical syndicate of France. Then, later, during the month of November last, when the general assembly of the Union of the Medical Syndicates of France met in Paris, Dr. Mignen was invited to preside. He had then the pleasure of hearing reports relating the practical results attained; among these was the establishment of an official tariff of fees to be paid under what in England would be called the Employers' Liability Act.

At first the law for compensating workmen in cases of accidents worked badly so far as the interests of the medical profession were concerned. The employers resorted to insurance companies which engaged the service of medical men at fixed salaries. The medical attendant was often accused of acting in the interest of his employers. He could do this by allowing the injured workman to return too soon to his work or by drawing up such medical certificates as tended to make the injury appear less grave. This would reduce the amount of compensation to be given by the insurance company that employed the medical man. But if injured workmen complained of the medical practitioner the latter had good cause to complain of the working men, of their employers, and of the State and its laws. A number of laws had been enacted which are described as laws "of social solidarity"—namely, laws increasing the responsibility of society as a whole towards such members of the society as suffer special disadvantages or misfortunes. The compensation for labour accidents was a notable example of such legislation. But in all this the position of the medical practitioners had been entirely overlooked and while the law was endeavouring to give special assistance to large sections

of the community, the members of the medical profession were threatened with a considerable reduction in their incomes. Fortunately, the parliamentary medical group remains intact. Not even the fierce quarrels engendered by the Dreyfus affair were able to break up this admirable organisation. All medical men, whether they be senators or deputies, and whatever the political party to which they belong, form part of the parliamentary group. When a Bill is introduced affecting the medical profession these political adversaries meet on the friendliest terms and discuss the proposed measure from the point of view of their profession. They at once saw that the law on accidents might be used by various organisations such as insurance companies to compel the victims of accidents to place themselves under the care of medical men specially engaged and probably badly paid for that purpose. Already in 1898 the parliamentary medical group succeeded in getting a clause added to the Bill which stipulated that any injured workman was free to select whatever medical attendant he might prefer.

The adoption of a clause reserving for the patient the right to choose his medical adviser established an important principle, but it did not suffice to secure its practical application. The insurance companies set up dispensaries near important works and in centres where accidents often happen. The employers on their side exercised pressure on their workmen. The workmen were free to do as they pleased but the employers were also free to discharge them. Thus it simply amounted to this, that the workmen were made to understand that if they did not employ their master's medical man then their master would not employ them. The purport of the law was therefore easily defeated. Moreover, the object of the medical unions was likewise set aside. The unions strive to maintain the dignity, independence, and impartiality of the medical profession. But here were medical men induced to sacrifice their independence and impartiality for the sake of the regular salaries offered them by the insurance companies. Fortunately, in 1904 the law was to be revised and the parliamentary medical group set to work again. This time they won over the Senate and the revised law of 1904 contains an additional clause imposing fines and punishments on employers and others who in any way, by threats or otherwise, interfere with the workman's free choice of the medical practitioner. The freedom of the worker is thus at last insured and since then he has been practically as well as theoretically able to choose his own medical attendant. The result is that the members of the medical unions have much more work while the medical men in the service of the insurance companies find their employment well-nigh gone.

Nor is this all. Not only have the independent members of the profession won back their patients, but they have advantageously settled the vexed question of fees. Thanks again to the activity of the parliamentary group an official commission was appointed to study the matter and to draw up a tariff of charges. This commission consisted of three delegates of the medical unions, and of delegates of the unions of dispensing chemists, of the employers' unions, of the workmen's unions, and of the insurance companies. In a word, the commission comprised representatives of all the interested parties. Three different tariffs were drawn up. One applies to rural districts, another to small towns, and the third to the large towns. The smallest sum to be paid for a visit is 1 franc 50 centimes; the highest, that is in Paris, 2 francs 50 centimes, or 2s. Of course, this does not include medicine, for French medical practitioners do not dispense. Then there is a very long and complicated tariff for all minor and major surgical operations.

What this means is best set forth by the estimate made by the union of the Paris medical practitioners. After patient and long inquiry they are now convinced that this alteration in the law has increased the income of the Parisian medical practitioners who attend injured workmen to the extent of £20,000 per annum. This is certainly a very substantial result and amply demonstrates the utility of forming medical unions.

(To be continued.)

CLERICAL AND MEDICAL GOLF MATCH.—A golf match took place at Burnham on March 19th between teams representing the clerical and medical professions of Bristol and Olifton. A high wind rendered play difficult, but the clergy eventually won easily.

quislite extension at Drumchapel will cost about £100,000. It is gratifying to note that at the meeting the Lord Provost was able to intimate a list of subscriptions already received amounting to £29,500.

March 25th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

University Education in Ireland.

It might have been thought that the announcement in Parliament that this question would not be dealt with for some time would have lessened the interest in it in Ireland; but it has not had that effect, for the most influential of the morning papers here contain daily columns of letters in reference to what is called "Mr. Bryce's scheme," although nobody knows what it may precisely prove to be. Many meetings have been held here, in England, and even in America, but the question remains unaltered because of the absence of definite knowledge. On March 22nd two demonstrations were held in Trinity College to protest against Mr. Bryce's scheme, as it is generally interpreted to be. The most prominent speaker at the principal meeting, which was held in the examination hall, and the resolutions were spoken to by Lord Ashbourne, Lord Iveagh, Sir Edward Carson, M.P., and many others. The *noli me tangere* policy has been fully adopted by the University of Dublin. It may succeed, or it may not, but the existing conditions have certainly worked well here for 300 years.

Motor-car Accident in Dublin.

Lady Thomson, wife of Sir William Thomson, was knocked down by a motor-car on March 23rd, just in front of their residence in Stephen's Green. The staff of St. Vincent's Hospital, situated a few doors off, were quickly at attendance. Sir William Thomson and her brother, Sir Hornley Stoker, arrived soon and it was ascertained that the patient, although badly bruised, was happily not seriously injured. The owner of the motor-car, who was also a driver, was brought before the chief magistrate on March 25th and remanded on bail pending the convalescence of Lady Thomson and her ability to appear in court.

The Belfast Health Commission.

During the past week the members of the Health Commission have spent their time in visiting mills, slums, and other places referred to in evidence. They also held one night sitting on March 20th, when some of the labour party tendered evidence as to work in the mills and as to filled up round. The Commission, owing to the Easter holidays, will sit again until April 8th, when it meets in the City Hall, Belfast. The Ulster Medical Society has nominated a number of members, Dr. A. Dempsey, Sir John Byers, Professor J. A. Lindsay, Dr. W. Calwell, and Dr. J. McCaw, to give evidence; and Dr. H. Stevenson, the honorary secretary, is to present a series of resolutions passed at various times by the Ulster Medical Society in regard to questions of public health.

Ulster Eye, Ear, and Throat Hospital.

At the annual meeting of the friends of this charity held on March 21st it was reported that there had been 2170 extern and 340 intern patients during the past year. The debt has been reduced from £324 10s. 6d. to £230 9s. 7d. 112 operations were performed.

The Public Health of Belfast.

At a meeting of the public health committee of Belfast held on March 21st the superintendent medical officer of health presented a dismal report. The death-rate for the week ended March 16th from all causes was 22.3 and from the principal zymotics 1.4. There were 18 cases of typhoid fever, ten of scarlet fever, 11 of diphtheria, and 24 of epidemic cerebro-spinal meningitis, as compared with 11, 13, three, and 31 for the previous week. The total number of cases of "spotted fever" since the outbreak of the disease was now 201, and there had been 107 deaths. The medical officer of health reported that there was great difficulty in persuading parents of children suffering from cerebro-spinal meningitis to have the patients removed to Purdysburn fever hospital for treatment, and he asked for instructions on the point, but after discussion

it was decided to leave the matter in his hands. It would have been better had he explained the objections that the parents of the patients have in regard to the hospital, but this will doubtless come out at the inquiry before the Health Commission. At Purdysburn fever hospital, which accommodates 168 patients, there are now 122 cases; of these 25 are suffering from typhoid fever, 39 from scarlet fever, 15 from diphtheria, and 39 from cerebro-spinal fever.

Cerebro spinal Fever.

Despite the fact that the disease is notifiable, that isolation is being promptly used, that it has been advised to boil the water and the milk; and that disinfectants are being given away profusely—so profusely that a deputation of chemists has complained to the public health committee of the unfairness of such lavishness—and, finally, that the weather has become much milder, cerebro-spinal meningitis continues its course apparently unchecked. Five deaths were reported on March 25th and six fresh cases were notified, and up to the present (March 26th) the total number of cases reported is 218, with 118 deaths. Both the medical profession and the public fear that the measures employed are not resulting in the stamping out of the epidemic.

March 26th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Aneurysm of the Ophthalmic Artery cured by Gelatin.

M. Lancereaux and M. Paulesco communicated a paper upon the above subject at the Academy of Sciences on March 4th. They gave the patient injections of gelatinised serum of a strength of 2 per cent. and after 41 injections arrived at a complete cure. Two hours after the first injection the blood in the aneurysmal sac coagulated, with the result that the aneurysmal bruit and the beating sensation disappeared, but as the conglum contracted after seven or eight hours the sac filled again with blood. Repeated injections gradually caused the sac to become quite full of clot, with the result that the bruit gradually got weaker, changing in quality, and finally the sac became completely and definitely obstructed.

A Possible Antidote for Strychnine.

On March 12th M. Pouchet communicated to the Academy of Medicine a letter addressed by the French consul at Batavia to the Minister for Foreign Affairs. Certain planters whose cocoa plantations had suffered much from the attacks of monkeys laid strychnine for them. It was then noticed that after the monkeys had eaten the strychnine they made for certain trees which they climbed and of which they proceeded to eat the leaves. Such monkeys never showed any symptoms of poisoning and continued their games as before. M. Pouchet thought that it would be interesting to get specimens of the leaves of these trees so as to see whether they really had any antidotal properties for strychnine.

Small-pox and Vaccination at Laos.

M. Kermorgant read a communication sent in by M. Roufflandi, a *médecin-major* of colonial troops, before the Academy of Medicine on March 12th on the subject of small-pox and vaccination at Laos from 1889 to 1906. The country in question, the area of which is 267,000 square kilometres, has only 500,000 inhabitants. The villages are, therefore, very distant the one from the other. There are only five medical men throughout the whole territory and they have to go their rounds either by horse or by elephant, or occasionally by steamer. In 11 years these medical men have performed 196,830 vaccinations with 49 per cent. of success, but it must be remembered that the vaccine which comes from Saigon is often from 55 to 60 days old. These medical men have also to resist strenuously the practice of small-pox inoculation which is still widespread in the country, but they have made one great step in advance, for at Hieng-Khouang on the plateau of Tranninh, which is 1200 metres above the sea, they have started a vaccine station which since the year 1905 has been able to furnish the whole of Haut-Laos with vaccine lymph.

March 25th.

being developed and there were now two roof shelters in constant use for the children. One of these was in full use last summer and many of the patients spent the whole of their time in this way in the open air. Turning to the question of finance the chairman, who, as all who are connected with the infirmary are aware, has brought to bear on this question keen business faculties coupled with an amount of large-mindedness not always associated therewith, said the weekly board had reason for congratulation that some success had attended its efforts towards economy. In 1905 there was a reduction in ordinary working expenditure of £400 and in 1906, notwithstanding an increase of four in the number of occupied beds, there was again a decrease of £410. He considered that this was due in part to a diminution in the cost of some of the articles consumed, but he credited the staff of the infirmary with some share in bringing the result about. The total expenditure for the year 1906 at the infirmary and at the two semi-convalescent hospitals had amounted to £35,044. It was true that this included a sum of £1717, which might be regarded as extraordinary expenditure, but he did not consider "extraordinary" expenditure should be regarded as a source of expenditure unlikely to recur. Of this sum £472 had been devoted to the addition to the clinical laboratory. The receipts for the year amounted to £30,814, or £4200 below the expenditure, but he was not discouraged by an examination of the details of the income. There had been, indeed, a slight decrease in the amount of the annual subscriptions and legacies amounted to only £1129, but the subscription from the Leeds Workpeople's Hospital Fund was £5250, which was the largest sum ever received from that source. The subscriptions from workpeople outside the city had also increased and amounted to £1439, while the infirmary received about £1000 more from this class through demonstrations and galas which they promoted in the towns and villages round about. Two beds and one cot had been endowed during the year by donations amounting to £2500. Among the factors which have contributed to the more economical working of the charity during the last few years must be included the systematising of the accounts which has been carried out by Mr. Blair, the general manager, and his staff, under the direction and at the instigation of Mr. Lupton. As a result of this there is circulated every month a large sheet showing not only the daily average number of beds occupied and the average cost per bed occupied but the amount actually expended in connexion with every ward in the infirmary, in the theatres, and in the various out-patient departments. Such sources of expenditure as provisions, dressings, drugs, massage, nurses' salaries, including that of extra nurses engaged, thermometers, glass urinals, &c., are all separately dealt with and the sheet enables one at a glance to see where undue expenditure appears to be going on and cannot fail to lead to a wise economy. In Leeds it is happily the rule that every member of the honorary staff of the infirmary is a member of the board of management and in consequence of this it has been possible to institute a rule, excellent in its intention and fruitful in its results, which it might have been otherwise difficult to introduce without misunderstanding. This rule involves the sending to every member of the staff a monthly, or in some cases a weekly, statement of the number of patients under his care who have been in the infirmary more than eight weeks, of those who are having massage or any specially expensive form of treatment, whether medicinal or surgical, and of those who are having stimulants. The members of the honorary staff would be the first to admit that extras ordered in suitable cases are occasionally through inadvertence continued when the necessity for them has ceased to exist. As showing the importance of apparently small economies Mr. Lupton in his address mentioned that the expenditure of 1d. more per head on one of the meals which was daily supplied to their patients, nurses, and staff servants, involved an increase of £1000 per annum.

Institution of Separate Professorships of Zoology and Botany at the University.

Consequent on the resignation of Professor Miall, who has occupied the chair of biology since the inception of the Yorkshire College in the early "seventies," the conditions of the teaching in the two subjects of zoology and botany have been fully discussed and at the last meeting of the council of the University it was decided to create separate chairs in the two subjects.

March 25th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Edinburgh Royal Infirmary: New Lady Superintendent of Nurses.

THE managers of the Edinburgh Royal Infirmary have appointed Miss Annie Warren Gill, R.R.O., to be lady superintendent of nurses in succession to Miss Spencer. Miss Gill is at present matron of the Royal Berkshire Hospital, Reading. She was trained in Edinburgh and was for some time night superintendent and for three years assistant superintendent of the Nurses' Home. She was in Africa during the war as matron of the Edinburgh and East of Scotland Hospital; she then returned to Edinburgh but was again sent out to Africa, having been selected by the Government for service in the concentration camps in the Orange River Colony. For her services in South Africa she received the decoration of the Royal Red Cross.

An Important Medico-legal Case.

An important trial has been concluded in Edinburgh which from its medico-legal aspect is worthy of note. The case was known as "The Camnock Shortbread Poisoning Case." When the man, who was charged with having sent the shortbread, was brought into court for trial it was submitted by the Crown that he was insane and this was supported by two medical certificates. Counsel for the prisoner opposed this view and insisted that the prisoner had consistently maintained his innocence and had instructed his agents and counsel to maintain his innocence. The court decided against the Crown and allowed the trial to proceed. The evidence against the accused was generally regarded as very weak, but the judge in instructing the jury pointed out to them that they had to consider whether the prisoner was insane or not. The jury, instead of returning one of the three ordinary verdicts, decided that the prisoner was insane, with the result that he is detained as a criminal lunatic during the King's pleasure, with the double stigma of insanity and criminality.

Demonstrations on Diseases of the Lower Animals.

At the request of the Faculty of Physicians and Surgeons, Glasgow, it has been arranged that the corporation veterinary surgeon should give a series of demonstrations to medical men on diseases of the lower animals, more especially with reference to those which are transferable to man. In connexion with this subject it is interesting to note that the Incorporated Sanitary Association has also approached the town council of Glasgow. The association is at present considering the question of instituting an examination for a certificate of competency in inspecting meat and other foods. For such an examination it is necessary that candidates should undergo a course of practical tuition in the various subjects of examination, such as the signs of health and disease in animals, dead or alive, intended for food, the names and situations of the organs in the bodies of animals, the duties of meat inspectors, &c. The association thinks that in the interests of public health the time has arrived when such a course of teaching should be established by the corporation and believes that it would be well supported.

The Royal Hospital for Sick Children, Glasgow.

At the invitation of the Lord Provost a conference of representative citizens was held in the municipal buildings last week to discuss the scheme for the foundation of a new and larger hospital for sick children in Glasgow. The present hospital, situated in Garnethill, contains 74 cots, while at the hospital at Drumchapel there are 24 additional cots, making 98 in all. At the present moment there are 140 cases awaiting admission to the hospital, and some idea of the immensity of the work carried on by the institution can be gathered from the fact that during last year alone 11,600 patients were treated at the outdoor department. The present hospital, which was erected in 1882, is unfortunately situated in the centre of a densely populated district and is overshadowed by tall tenements on either hand. The directors have therefore determined, if possible, to erect a larger hospital on a new site in Glasgow and also to extend the branch in the country at Drumchapel. To be at all adequate the new hospital will require to contain from 200 to 250 cots and to erect such a building on a suitable site and make the

urgeo Flood was buried in the barracks at Fort Churchill in Hudson Bay, his being the first death and the first grave in the history of the Royal North-West Mounted Police in the Hudson Bay district.

The Academy of Medicine, Toronto.

The Ontario Medical Library Association, with a fine library and building fully paid for, has amalgamated with the Toronto Clinical Society, the Toronto Medical Society, and the Toronto Pathological Society into the Academy of Medicine, Toronto. The Academy will be managed during the first year by a council of 12, which will be composed of the officials of the Library Association and the president and secretary of the other three societies. Succeeding councils will be composed of 19 members. Besides the ordinary members there will be resident and non-resident fellows. An addition will be built to the present building at a cost of \$50,000 to provide for a fireproof library and auditorium. Dr. J. F. W. Ross is the president of the Library Association, Dr. H. B. Anderson of the Toronto Clinical Society, Dr. R. D. Rudolf of the Toronto Medical Society, and Dr. J. A. Amyot of the Toronto Pathological Society. The Academy will be composed at first of four sections—namely, the library section, the medical, the surgical, and the obstetrical sections.

Patent and Proprietary Medicines.

The Hon. Mr. Templeman, from British Columbia, has introduced into the Dominion House of Commons a Bill the chief provisions of which are as follows. Every manufacturer or importer of medicines, or agent of such manufacturer or importer, before offering such medicines for sale shall submit to the Department of Inland Revenue two samples of such medicine so manufactured, together with the name of the medicine and a statement declaring whether the medicine does or does not contain alcohol or any of the poisons set forth in the schedule attached. With such samples a fee is also to be transmitted when, if found satisfactory, a licence will be issued. The Bill will also provide for fines and penalties for non-compliance with the provisions of the law.

Royal Victoria Hospital, Montreal.

The number of patients admitted into the wards of the Royal Victoria Hospital, Montreal, during the last hospital year was 3444, an increase of 351 over the previous year. Of this number 1989 were free patients, 1021 public ward patients, and 434 private ward patients. The total days' hospital treatment was 73,993. In the outdoor departments the total number of patients treated was 4229. The income for the year was \$160,436, while the ordinary expenditure amounted to \$130,353, the balance of \$30,082 being applied in the reduction of the indebtedness incurred by new buildings. Dr. W. F. Hamilton and Dr. C. F. Martin were appointed physicians to the hospital. Dr. Francis J. Shepherd was appointed consulting surgeon, retaining his position as surgeon at the General Hospital.

Toronto General Hospital.

For the year ending Sept. 30th, 1906, there were in residence in the Toronto General Hospital each month the following patients: October, 1905, 313; November, 319; and December, 311; January, 1906, 325; February, 356; March, 341; April, 299; May, 293; June, 292; July, 278; August, 261; and September, 267. The average length of stay per patient was 27.19 days. The cost per head per day was \$1.337. There were performed in the main theatre 905 operations; in the pavilion theatre, 239; and in the eye and ear department, 162. On Sept. 30th, 1906, there were 175 males, 122 females, and eight children in the hospital. During the year there were admitted 2121 males and 1462 females and there were born in the hospital 197 children. The patients remaining in the institution on Sept. 30th, 1906, were 264 adults and 15 children.

Toronto, March 14th.

PRESENTATION TO A MEDICAL PRACTITIONER.—On March 4th Dr. H. P. Taylor of Mid Yell, Shetland, was presented by his friends and patients in the islands of Yell and Fetlar with a Blotkenderfer typewriter and case and a cheque as a mark of their esteem. Mrs. Taylor was presented with a case of fish knives and forks.

Obituary.

SURGEON-GENERAL SIR JOHN HARRIE KER INNES,
A.M.D. (RKT.), K.O.B., K.H.S., F.R.C.S. ENG.

FULL of years and honours this distinguished surgeon died on Tuesday, March 12th, in Florence, at his residence in the Piazza dell' Indipendenza, and on the Friday following at the Protestant Cemetery of the Allori, in the presence of many mourners, British, Colonial, and American, the urn containing his ashes was placed beside the grave of his wife who predeceased him in 1901. Though for some time back in failing health, Sir John Innes seemed to possess a wonderful rallying power, and less than three weeks ago he surprised his friends at the Florence Club by dropping in, just as he used to do in the old days, and joining in conversation with his wonted vivacity. But that was his last appearance in public. The influenza, which has numbered many victims during all the winter along the French and Italian Riviera and in the landward winter cities, claimed him also, double pneumonia supervened, and after a brief struggle he passed peacefully away.

Born in 1820 of Scottish parentage—his father was the Rev. J. B. Innes—he showed an early predilection for medical study and was educated at University College, London. In 1841 he obtained the diploma of the Royal College of Surgeons of England. Entering the Army Medical Department in 1842 he was destined to see a good deal of war service in the course of his army career. To begin with, he gained much valuable experience in the Crimean campaign of 1854 where he served as a volunteer and took part in the attack on the Redan on June 18th. He then proceeded to India and served with great distinction throughout the Indian Mutiny with the 1st Battalion of the 60th Rifles, and more especially in connexion with the action on the Hindun, the battle of Budlee-ke-Seral, and the storming of the heights before Delhi, and the siege, assault, and capture of that city. He bore an honourable part during the eventful days of Delhi and Rohilkund. Acting as principal medical officer of Sir John Jones's force, he went through the Rohilkund campaign and subsequently held a like appointment in Oude with Brigadier Troup's column. In recognition of his services during the Mutiny he received the O.B. and was promoted a deputy-surgeon-general in 1858; surgeon-general in 1872. In 1871 he was selected to act as British medical commissioner on the staff of the Crown Prince of Prussia during the Franco-German war and at the close of this campaign he received the war medal and the Iron Cross. From 1876 to 1880 he held the appointment of principal medical officer in India and in 1878 he was appointed an honorary surgeon to Queen Victoria. In 1878-79 Surgeon-General Innes's duties as principal medical officer took him to Afghanistan and he was present at the assault and capture of Ali Musjid and the subsequent advance up the Khaiber Pass. Retiring in 1880, he was promoted to be a Knight Commander of the Bath in 1887 and on the death of the Queen he was gazetted to the K.H.S. which he held at his death.

Elected Fellow of the Royal College of Surgeons in 1860, in 1863 he married Miss Victoria Baker, daughter of Mr. N. Baker, who, all through his subsequent professional career and in his retirement in Florence, contributed much to make his house the resort of lovers of fine art—of music especially.

When Sir John Innes's active life, professionally speaking, came to a close he took up his residence in Florence, but he continued to intervene in beneficent work of all kinds, chief of which was the part that he bore in administering the British Relief Fund in aid of those who have been overtaken by ill-health and the indigence which it often brings with it in the Tuscan capital. He was a zealous promoter of other local charities, while his work on the reconstruction committee of the Church of the Holy Trinity contributed much to make that edifice what it is universally admitted to be—one of the most beautiful, as it is one of the most frequented, of the Anglican churches on the continent. Other interests also found in him an active and genial votary, the Florence golfing club being only less indebted to his support than the private theatricals and the musical recitals which (with the personal intervention of Lady Innes) did much to make "la vita fiorentina" enjoyable to the English-speaking colony—resident or migratory.

difficulty. Six months ago he sustained a severe fracture of the thigh caused by an accident in the hunting field, and he never afterwards regained his strength. The illness to which he succumbed was a virulent form of typhoid fever. This sad and early termination of Dr. Murray's promising career will cause great regret to a large circle of friends not only in South Africa, but also among his old fellow students in England, and much sympathy will be felt with his wife and two little children in their bereavement.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr. Oscar Israel, *Custos* of the Berlin Pathological Institute, in his fifty-third year.—Dr. Erb (son of the Heidelberg professor), assistant in the Strasburg University Medical Clinic.—Several continental journals reported recently the death of Dr. Roux, professor of surgery in Lausanne. We are glad to hear that the report is without foundation. Professor Roux has, however, been suffering from an attack of pneumonia, from which he is now convalescent.

Medical News.

SOCIETY OF APOTHECARIES OF LONDON.—At examinations held recently the following candidates passed in the subjects indicated:—

Surgery.—F. A. Bainbridge (Sections I. and II.), St. Bartholomew's Hospital; A. E. Blythman (Sections I. and II.) and S. P. Fouracre (Section I.), Charing Cross Hospital; A. F. Palmer (Sections I. and II.), Cambridge and Middlesex Hospital; and A. Shepperd (Sections I. and II.), Guy's Hospital.
Medicine.—F. A. Bainbridge (Sections I. and II.), St. Bartholomew's Hospital.
Forensic Medicine.—F. A. Bainbridge, St. Bartholomew's Hospital; and E. S. Cooke, Royal Free Hospital.
Midwifery.—P. A. Bainbridge and H. Morris, St. Bartholomew's Hospital; E. H. Paterson, Guy's Hospital; and W. F. Skinner, Sheffield and University College Hospital.
The diploma of the Society was granted to the following candidates, entitling them to practise medicine, surgery, and midwifery:—F. A. Bainbridge, A. E. Blythman, A. F. Palmer, and W. F. Skinner.

UNIVERSITY OF CAMBRIDGE.—At a congregation on March 14th the following degrees were conferred:—

M.D.—G. H. L. Whale, Jesus; F. E. Shipway, Christ's; and W. B. Heywood, Emmanuel.
M.B.—W. O. Pitt, Emmanuel.

—The General Board of Studies proposes the appointment of a second additional demonstrator of physiology, without stipend from the University, in Professor Langley's department.

TRINITY COLLEGE, DUBLIN.—At examinations held in Hilary term the following candidates were successful:—

FINAL MEDICAL EXAMINATION.

Part II.—**Surgery.**—Frank B. Seymour, John Gray, Ernest Jameson, Edward O. Stonor, George G. Vickery, Francis W. H. Bigley, Henry P. Hart, Albert T. J. McCreery, Arthur F. Knapp, Rev. Richard B. Bryan, John W. Lane, George H. Stack, and John H. Morton.

INTERMEDIATE MEDICAL EXAMINATION.

Part I.—Robert E. T. Tatlow, Victor B. Kyle, Hugh S. Metcalfe, William P. H. Smiley, Charles D. Hannan, Charles B. Jones, Desmond Drew, James D. Murphy, and Alexander K. Cosgrave.

DIPLOMA IN PUBLIC HEALTH.

Part I.—Cecil Scalle.

FOREIGN UNIVERSITY INTELLIGENCE.

Algiers. Dr. Bouin of Nancy has been appointed Professor of Pathological Anatomy and Histology in succession to the late Dr. Planteau.—**Basle.** Dr. Max Wilms of Leipzig has been appointed Professor of Surgery in succession to Professor Eaderlen who goes to Würzburg. Dr. Leopold Rütlimeyer, *privat-docent* of medicine, has been promoted to an Extraordinary Professorship. Dr. Dietrich Gerhardt of Jena, who had been offered a chair in Erlangen, has decided to accept instead the Professorship of Pharmacology in Basle.—**Berlin.** Dr. Eugen Hollander and Dr. Heinrich Riess have been granted the title of Professor. Dr. Philipp Bockenhelmer has been recognised as *privat-docent* of Surgery.—**Berne.** Dr. Léon Asher has been appointed Extraordinary Professor of Physiology.—**Bordeaux.** Dr. Cruchet has been appointed, after competition, *agrégé* in medicine.—**Florence.** Dr. Luigi Lenzi has been recognised as *privat-docent* of

External Pathology.—**Göttingen.** Dr. Bruno Salge of Dresden has been appointed Extraordinary Professor of Children's Diseases. Dr. F. Samuley has been recognised as *privat-docent* of Medicine.—**Greifswald.** Dr. Leopold Heine of Breslau has been appointed Professor of Ophthalmology in succession to Dr. Schirmer.—**Groningen.** Dr. A. Klein of Amsterdam has been appointed Professor of Hygiene, Forensic Medicine, and Pharmacology.—**Kiel.** Dr. Otto Schirmer of Greifswald has been appointed Professor of Ophthalmology in succession to Dr. Völckers, resigned.—**Liège.** Dr. Ravlart and Dr. Breton have been appointed, after competition, *agrégés* in Medicine.—**Lyons.** Dr. J. Lépine, Dr. Lesieur, and Dr. Martin have been appointed, after competition, *agrégés* in Medicine.—**Marburg.** Dr. W. Danielsen has been recognised as *privat-docent* of Surgery.—**Montpellier.** Dr. Lagriffoul, Dr. Leenhardt, and Dr. Gausseil have been appointed, after competition, *agrégés* in Medicine.—**Naples.** Dr. Giuseppe Lucibelli has been recognised as *privat-docent* of Medicine.—**Paris.** Dr. Castaigne, Dr. J. Sicard, Dr. Nobécourt, Dr. Jousset, and Dr. Loëper have been appointed, after competition, *agrégés* in Medicine.—**Paria.** Dr. Guido Sala has been recognised as *privat-docent* of Neurology and Mental Diseases.—**Pisa.** Dr. Taddeo De Hieronymis has been recognised as *privat-docent* of Hygiene.—**Prague (German University).** Dr. Eischnig of Vienna has been offered the chair of Ophthalmology to succeed the late Professor Czermak. Dr. Kretz of Vienna has been offered the chair of Pathological Anatomy in succession to Professor Chlari who goes to Strasburg.—**Rio de Janeiro.** Dr. José Antonio Abreu Fialho has been appointed Professor of Ophthalmology in succession to the late Dr. da Cunha.—**Rome.** Dr. Riccardo Dalla Vedova has been recognised as *privat-docent* of Surgery and Operative Medicine.—**Strasbourg.** Dr. Karl Pfersdorff has been recognised as *privat-docent* of Psychiatry.—**Toulouse.** Dr. Dalous has been appointed, after competition, *agrégé* in Medicine.—**Turin.** Dr. Giuseppe Gavello has been recognised as *privat-docent* of Oto-rhinolaryngology. Dr. G. Battista Allaria has been recognised as *privat-docent* of Children's Diseases.—**Vienna.** Dr. Otto Zuckerkandl, *privat-docent* of Surgery, and Dr. Max Salzmann, *privat-docent* of Ophthalmology, have been granted the title of Professor.—**Würzburg.** Dr. Alfred Sommer has been recognised as *privat-docent* of Comparative Anatomy and Histology.

CENTRAL MIDWIVES BOARD.—A meeting of the Central Midwives Board was held on March 21st at Carlton House, Westminster, Dr. F. H. Champneys being in the chair. The following letter, concerning the midwives roll, addressed to the secretary of the Central Midwives Board was received from the Privy Council:—

SIR.—Referring to your letter inquiring whether the Central Midwives Board has power under the Midwives Act, 1902, to remove the name of a midwife from the roll for reasons other than misconduct I am directed by the Lords of the Council to state that the object of the Act being to provide women in childbirth with the attendance of properly qualified persons, it is, in their lordships' opinion, clearly part of the duty of the Central Midwives Board in respect of what "may be necessary for the due and proper carrying out of the provisions of the Act," to withdraw certificates from persons who are either too old or infirm, or for any other reason incapable of discharging their functions in the event of application being made to them to that effect.

An application was considered from a midwife, Susannah Davies, for the removal of her name from the roll on the ground of defective hearing and memory. The Board resolved to grant the application and directed the secretary to remove her name from the roll of midwives. A letter from Dr. J. Niven, medical officer of health of Manchester, was received reporting a conviction under Section 1(1) of the Midwives Act protecting the title of midwife. A letter was considered from Dr. Sidney Barwise, county medical officer of Derbyshire, as to the licensing and inspection of certified midwives taking cases into their own homes. The Board resolved to refer the letter to the Act Amendment Committee when formed.

HOLIDAYS FOR WORKING LADS.—The "Clerk of the Weather" is more often blamed than praised in our varying climate, but in the eighteenth annual report of the Sea-side Camps for London Working Boys thanks are accorded to the "glorious summer of 1906" for its share in securing the success which has once more crowned the work of the committee. 2551 lads were received at the camps at Bexhill, Eastbourne, and Dymchurch and glowing accounts of their enjoyment are given in this report. Bishop Taylor Smith, Chaplain-General to the Forces, spent a week at Bexhill camp

This is not the place to speak of his private benevolence, which was as large as it was unobtrusive. Let it suffice to say that by his death the Florentine community is in many ways the poorer, as it will continue to realise for some years to come.

CHARLES JAMES OLDHAM, F.R.O.S. ENG., L.R.O.P.
LOND., L.S.A.

THE late Mr. Charles James Oldham of 38, Brunswick-square, Brighton, supplied in himself a remarkable instance of proficiency in two rather dissimilar pursuits. By profession an ophthalmic surgeon he made instrumental music his pastime and became quite celebrated for his collection of Stradivari violins. As already mentioned in our columns, Mr. Oldham died at Brighton on Jan. 24th after an attack of broncho-pneumonia of about 12 days' duration. He was born on Jan. 22nd, 1845, being the eldest son of Mr. James Oldham, F.R.O.S., who began practice in Brighton in January, 1840, travelling there by the first train which went through from London. Mr. James Oldham was one of the founders of the Sussex Medico-Chirurgical Society and was its first secretary. The family is said to be descended from a Lancashire family, one member of which was Hugh Oldham, Bishop of Exeter, who founded Manchester Grammar School, united with Bishop Fox in endowing Corpus Christi College, Oxford, and died in 1519. Mr. Charles Oldham received his school education at Rugby under Dr. Temple, and when a youth was a keen football player. From 1866 to 1871 he studied medicine at Guy's Hospital, where his uncle, Dr. Henry Oldham, had been one of the physicians. In 1870 he took the diplomas of M.R.O.S. Eng., L.R.O.P. Lond., and L.S.A.; in 1871 he was admitted F.R.O.S. Eng. At Guy's Hospital he held the appointments of house physician, house surgeon, and resident accoucheur. He was also resident medical officer at the Evelina Hospital for Sick Children and clinical assistant at the Royal Ophthalmic Hospital, Moorfields. In 1873 he commenced practice in Brighton in partnership with his father until the retirement of the latter in 1880. Mr. Oldham's surgical proclivities were mostly in the direction of ophthalmology and as early as 1872, at the International Ophthalmic Congress held in London, he read an account of an improved refracting ophthalmoscope. His hospital appointments included those of surgeon to the Brighton Hospital for Diseases of the Eye, consulting surgeon to the Brighton Blind Asylum, and assistant surgeon to the Central London Ophthalmic Hospital. In 1886 he was president of the Ophthalmological Section of the British Medical Association; he was also vice-president of the Ophthalmological Society and a member of the council; in the Brighton and Sussex Medico-Chirurgical Society he filled the offices of president and treasurer.

Mr. Oldham's musical abilities procured for him the positions of a director of the Royal Academy of Music and president of the Brighton Sacred Harmonic Society. For many years he played in the orchestra among the first violins at the society's concerts and he led the orchestra at the Good Friday performances of the "Messiah." His collection of Stradivari instruments, already referred to, included three violins, a viola, and a violoncello. For one of these he paid over £3000 and it has recently been on sale for £3500. One violin and the viola were made by Stradivari for the King of Spain. These various instruments were, with one exception, bequeathed by him to the British Museum. Since the publication of the details of the will regrets have been expressed that these masterpieces should be deposited in the British Museum, where they would only be seen in a glass case and would never be played upon. The explanation is, we believe, that the deceased had a great aversion to art treasures of any kind leaving the country and a great dread of their being stolen. His object, therefore, was to place his own collection in keeping where it would not be sold, stolen, or sent out of the country.

Mr. Oldham left estate valued at £77,959 gross, with net personalty £77,418, and of this he has set aside about £80,000 for educational purposes. The chief of the bequests are £10,000 to Corpus Christi College, Oxford, for the encouragement of general learning and of studies of classics; £5000 each to the Universities of Oxford and Cambridge for scholarships for proficiency in classics and in the works of Shakespeare; £3000 to the Manchester Grammar School, founded by his kinsman, Hugh Oldham, formerly Bishop

of Exeter; and £5000 to Epsom College. There are also bequests of £1000 each to the Medical School of Guy's Hospital, the Royal Academy of Music, the Sussex Eye Hospital, the Brighton, Hove, and Preston Dispensary, the Brighton and Sussex Medico-Chirurgical Society, the Brighton Sacred Harmonic Society, and the Actors' Benevolent Fund. The bequest to Guy's Hospital is for a prize in ophthalmology and that to the Royal Academy of Music is intended for the foundation of a violin scholarship. Subject to various bequests or legacies to relatives, friends, and servants he leaves the residue of his property to Corpus Christi College and the Manchester Grammar School. The funeral took place at the Extra-Mural Cemetery, Brighton, on Jan. 29th, and was very largely attended.

CHARLES WEST, L.D.S. R.O.S. ENG.

Mr. Charles West, of 41, Finsbury-square, E.C., died somewhat unexpectedly on March 8th from pneumonia following an operation at the German Hospital, Dalston, N.E. He took the diploma of L.D.S. R.O.S. Eng. in 1863 and had been honorary dentist to the German Hospital for about 35 years; he had also for many years acted in a similar capacity at Queen Adelaide's Dispensary, Bethnal Green-road, N.E. Mr. West was a member of the Odontological Society and a past president of the Metropolitan branch of the British Dental Association. He took a great interest in microscopical research and was a member of the Quekett Society and Selborne Society. He had travelled extensively in Europe and America. In his younger days he was a lieutenant in the Tower Hamlets Volunteers and had gained several prizes for shooting. His death will be regretted by a large number of private and professional friends. The mortal remains were cremated (by the wish of the deceased) at Golders Green, Hampstead, on March 12th, and the funeral took place at Highgate Cemetery on the following day, the Rev. Percy Martin officiating.

JAMES GOOD CURTIS, F.R.O.S. IREL., L.R.O.P. EDIN.

Much regret was felt amongst members of the medical profession in Cork when on March 4th it was publicly announced that Mr. J. Good Curtis had breathed his last on the previous day. It was generally known that he had been suffering from aortic aneurysm and that his condition was serious, so that the end was not unexpected. For a number of years he was a prominent personage in Cork and held more public appointments than any other medical man in that city. He was for a long time surgeon to the South Infirmary and for some years past was consulting surgeon to that institution. He was also inspector of anatomy, certifying factory surgeon, and medical officer of constabulary. His funeral was very representative. The cortege was led by about 50 members of the Royal Irish Constabulary in charge of a district inspector. Next came about 25 of the nurses of the South Infirmary in their picturesque green uniforms. Then followed quite a number of members of the medical profession immediately in front of the bier on which there was a number of floral wreaths, amongst them one from his medical colleagues at the South Infirmary. The chief mourners were his son, Colonel Curtis, R.A.M.C., and his son-in-law, Colonel MacCarthy. The general public were represented by prominent citizens. Mr. Curtis always took the most roseate view of life and had that happy disposition which results in making many friends and few enemies.

FRANK EVERITT MURRAY, M.B., B.O. CAMB.,
F.R.O.S. ENG.

Dr. Frank Everitt Murray, who died at Graaf Reinet, South Africa, on Feb. 1st, was the youngest son of Mr. W. E. Murray of Roodbloom, Graaf Reinet. He began his medical training at St. John's College, Cambridge, in the autumn of 1894. Having taken his degree in the Natural Sciences Tripos in 1899, he entered as a student at St. Bartholomew's Hospital, London, whence he graduated as M.B., B.O. Camb. in 1901. In 1902 he acted as house surgeon to Mr. John Langton at St. Bartholomew's Hospital and in the following year he became a Fellow of the Royal College of Surgeons of England. Returning to South Africa, he resided in Cape Town for a few months and afterwards joined Dr. J. L. Rubidge in Graaf Reinet, where he had endeared himself to the public and the profession, and his advice was much esteemed by his colleagues in cases of

had already occurred; that the local hospital was full of patients suffering from this disease; and whether he would make immediate inquiries as to the cause of this epidemic, which was attributed to the extreme destitution of the people consequent on the failure of the potato crop last year.—**MR. BURELL** (in a written reply) said: An outbreak of typhus fever occurred in this district early in February, since when four families, comprising 25 persons, have been affected. Three deaths have occurred, 16 persons are still in the fever hospital, and six have been discharged cured. The Local Government Board has already investigated the matter and is satisfied that the outbreak was not due to the destitution of the people but to insanitary conditions. None of the people affected were destitute and none had applied for relief at the time of the outbreak. The local medical officer of health, in consultation with the medical inspector of the Local Government Board, is making every possible effort to prevent the spread of the disease. Three additional fever nurses have been appointed by the guardians. There is every reason to hope that no further cases of fever will occur.

The Treatment of Tuberculosis in Parochial Infirmarys.

MR. WILLIAM PEARCE asked the President of the Local Government Board whether he would state which metropolitan parochial infirmaries had special wards for the treatment of cases of pulmonary tuberculosis; and whether the Local Government Board could encourage the establishment of such wards.—**MR. JOHN BURKS** sent the following written reply: In the majority of the metropolitan Poor-law infirmaries special wards are set aside for these cases. The general practice is to extend this system and I desire to encourage it in every way in my power.

Vaccination Wounds.

MR. LUDLOW asked the President of the Local Government Board whether Dr. Fletcher reported on the case of Olive Hunt, who died after vaccination, whether the same Dr. Fletcher reported on the case of Willy Kellam, vaccinated on Oct. 30th, 1906; whether the wound in this case took 72 days to heal; and whether he would lay a copy of Dr. Fletcher's reports upon the table of the House, or give a copy of the report to the relatives.—**MR. BURKS** (in a written answer) replied: Dr. Fletcher reported on both these cases. I do not know the precise number of days which the wound took to heal in the case of Kellam. The reports were made for my information and are confidential documents. Hence I could not take the course suggested in the last part of the question.

Medical Attendance on Coastguards in Buts.

MR. LAMONT asked the Secretary to the Admiralty what was the salary paid for medical attendance on the coastguard of Lamlash and Kildonan respectively in the county of Buts.—**MR. EDWARD ROBERTSON** answered: Dr. Robert Jamieson, surgeon and agent, who attends both the Lamlash and Kildonan detachments, is not in receipt of a fixed salary but is paid at the ordinary rate laid down in the instructions to Admiralty surgeons and agents. If my honourable friend wishes, I can furnish him with a statement of the actual amount paid to Dr. Jamieson during the last financial year in respect of these two stations.

Tuberculous Cows.

SIR ARTHUR BIRCHALL asked the President of the Local Government Board whether his attention had been called to the statement made by Professor McCall that the milk from a cow suffering from tuberculous mammitis should on no account be used for human food, and that such an animal should be destroyed or fattened for the butcher; and whether he would take such action as would prevent such animals being fattened for the butcher to the danger of the public.—**MR. BURKS** replied in writing: I have not seen the statement referred to. The report made in 1893 by the Royal Commission on Tuberculosis, presided over by Sir Herbert Maxwell, contained a statement of the principles upon which it considered that meat inspectors should act in dealing with the carcasses of animals affected with tuberculosis, and the Local Government Board has more than once brought the views of the Commissioners under the notice of local authorities. The Royal Commission, however, did not go so far as to recommend action of the kind referred to in the last part of the question. A further Royal Commission is now considering the transmission of tuberculosis from animals to man, and I should expect guidance from it as to the course which should be taken with regard to the meat of animals affected by the disease. Meanwhile, I could not undertake to promote the legislation which would be necessary to give effect to the suggestion of the honourable Member.

Lead Poisoning in the Potteries.

MR. JOWETT asked the Secretary of State for the Home Department whether any special inquiry was being made into the cause of the recent increase of fatal cases from lead poisoning in the Potteries.—**MR. GLADSTONE** wrote in reply: The figures of fatal and non-fatal cases of lead poisoning for the first two months of this year show ten cases, as against 19 for the corresponding months of the year before. But of these ten cases four have been fatal, as against none for the first two months of last year. With small numbers irregularities are sure to arise in the records of accidents of all kinds. I do not think any explanation can be given of the number of deaths for this year, which I am informed appear to be due to chronic kidney disease originated by lead poisoning of old standing.

MONDAY, MARCH 25TH.

Infants and Alcohol.

MR. SIMMONS asked the Secretary of State for the Home Department whether he was aware that recent investigation had established the fact that in many quarters of London and other large towns every day crowded with women, who not only took their little children into the heated atmosphere of the public bar but also doled their infants with the alcohol; that eminent expert authorities attributed the physical and moral deterioration of certain classes of the people to the fact above stated; and whether in the coming Licensing Bill he would consider the urgency of including a provision that no child should under any pretext whatever be allowed to enter a public-house.—**MR. GLADSTONE** replied: I do not think the state of affairs is as bad as represented by the question, but although it is neither new nor recently discovered the matter is serious and is engaging my earnest attention.

TUESDAY, MARCH 26TH.

Soldiers and Tuberculosis.

MAJOR SEELY asked the Secretary of State for War whether, in view of the fact that only some 6 per cent. of soldiers discharged from the army last year suffering from tubercle of the lung were sent to hospital or sanatoriums, while more than 70 per cent. were sent direct to their homes he could take steps to insure that a larger proportion should in future be sent to institutions where they could receive proper treatment.—**MR. HALDANE** said in reply: The disposal of soldiers invalided with tubercle of the lung is a matter involving several difficult considerations, and I propose to institute a small committee to advise as to what steps it may be practicable to take in the direction indicated by the question. I hope my honourable and gallant friend will give his services to this committee.

Calico and Blood-Poisoning.

MR. SUMNERBELL asked the Secretary of State for the Home Department whether his attention had been called to an inquest held at Sunderland on March 18th as to the death of Ann Wilson, aged 16 years, during the hearing of which the house surgeon at the infirmary said that death was due to blood poisoning, which had been set up by the dressing from the calico, the coroner further remarking that the calico was laden with as much dressing as manufacturers cared to put into it for trade purposes, either to obtain a better price for it or to improve its appearance; and, if so, whether it was his intention to introduce any legislation having for its object the restriction of the sale of calico containing matter of such a dangerous character.—**MR. GLADSTONE** replied: I have obtained a piece of this calico and I am taking steps to obtain an expert opinion upon it and upon all the circumstances of the case.

Insanitary Workshops.

MR. RAMSAY MACDONALD asked the Secretary of State for the Home Department how many complaints as to dirty or otherwise insanitary workshops and factories had been sent by the factory department to the metropolitan borough councils during the 12 months ending Feb. 23rd last; also the number of prosecutions instituted and cases brought before the court by officers of the metropolitan borough councils for overcrowding or insanitation in such factories or workshops.—**MR. GLADSTONE** answered: The number of notices sent by the men inspectors to the metropolitan borough councils during the period named in the question with regard to insanitary conditions in factories and workshops was 488. I have not been able at such short notice to obtain the number of those sent by the women inspectors, but the number in 1906 was 238. I have not the number of prosecutions instituted by the borough councils in respect of insanitary conditions during the period in question, but the figure for 1905, as given by the returns of the medical officers of health, was 19.

Medical Assistance for the Poor in Scotland.

MR. CATHCART WASON asked the Secretary for Scotland whether, in view of the fact that parish councils could not use money out of the rates to compel a medical man to provide an assistant for the general benefit of the public, he would put into operation the powers of the Local Government (Scotland) Act to protect the interests of the poor.—**MR. SIMONAIR** said, in reply: I am informed that the Local Government Board for Scotland have no authority to see that medical assistance is provided for other than the legal poor. The duty of provision for them lies with the parish council.

Medical Attendance in the Navy.

Answering **MR. BOWLES**, **MR. GEORGE LAMBERT**, Civil Lord of the Admiralty, stated that medicines and free treatment for 30 days in hospital were given to men and boys in the Royal Navy.

BOOKS, ETC., RECEIVED.

as chaplain and endeared himself to officers and lads alike. A visitor at Dymchurch writes: "Think of the tremendous change it must be to a London boy living in a noisy thoroughfare where the din is incessant or in an over-crowded slum to find himself in the open country with hardly a house in sight, with no sounds to wake him in the early morning, save the voice of the lark or the call of the reveille bugle! It is indeed a new experience and one which many of these lads would never get were it not for these camps. Surely, to make it possible for them to live a healthy, happy, human life, far removed from the temptations inseparable from great towns, surrounded by influences that make for righteousness, is a religious thing, a deeply spiritual thing. And so I cry, 'God bless the Seaside Camps for the London Working Boys.'" Increased support is asked for and it should be remembered that it is important that an organisation of this kind should have its funds in hand as early as possible in the year, so that it may know in good time how many boys it can undertake to provide for. The office is at 23, Northumberland-avenue, London, W.C., and the secretary is Mr. F. Abel Bloxam.

UNIVERSITY OF LEEDS—The results of the Second and Final (Part I.) Examinations for the degrees of M.B., B.Ch., were issued on March 22nd. The following passed Part II. of the Second Examination (Anatomy and Physiology)—viz., J. P. Munson, B. O. Piercey, A. Riley, W. Shaw, R. E. Smith, and J. N. L. Thoseby. In Part I. of the Second Examination (Materia Medica), A. Perlman passed. In Part I. of the Final Examination the following passed: J. H. M. Frohisher, G. A. O. Mitchell, and G. O. H. Nicol.—At a recent meeting of the council of the University the following, who are lecturers of the University, were elected to the Faculty of Medicine—viz., Arthur G. Plumley, M.B. Lond., L.D.S. Eng., lecturer on dental surgery; Thomas S. Carter, L.D.S. Eng., lecturer on operative dental surgery; A. Alan Forty, L.D.S. Eng., lecturer on dental anatomy and physiology; and O. Rippon, L.D.S. Irel., lecturer on dental mechanics. Dr. Plumley was also elected a member of the Board of the Faculty of Medicine. At the same meeting of the council the dental committee or honorary dental staff of the Leeds Public Dispensary was requested to nominate two of its members for election as members of the dental committee of the Board of the Faculty of Medicine. The effect of this will be to secure for the clinical part of the School of Dentistry a direct representation in the University.

DEATH OF A CENTENARIAN.—Mrs. Brunt of Berrow, Somerset, died on March 20th, aged 101 years and four months.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

Poor-law Medical Officers in Scotland.

MR. GATHCART WATSON has presented a petition to the House of Commons from the Poor-law medical officers of Scotland praying that the disabilities under which they have laboured since the passing of the Local Government (Scotland) Act of 1894 might be removed.

Pharmacopœial Formulas for Patent Drugs.

The international agreement respecting the unification of the pharmacopœial formulas for patent drugs, which was signed at Brussels on Nov. 29th, 1906, has been presented to both Houses of Parliament. Its text is now published in French and English. The agreement is signed by representatives of Great Britain, Germany, Austria and Hungary, Belgium, Bulgaria, Denmark, Spain, the United States, France, Greece, Italy, Luxembourg, Norway, the Netherlands, Russia, Servia, Sweden, and Switzerland.

Deaths from Tetanus.

On the motion of Sir WILLIAM COLLINGS in the House of Commons, a return has been ordered of papers containing the results of an inquiry into the origin of certain deaths from tetanus in the Punjab consequent on the employment of Haffkine's prophylactic against plague.

Municipal Milk Depôts.

Mr. JOHN BYRNS has presented a Bill in the House of Commons "to authorise and regulate the establishment of milk depôts by certain local authorities and for matters incidental thereto."

Education of Afflicted Children (Ireland) Bill.

Mr. CHARLES CRAIG's Bill to provide for the better education of afflicted children in Ireland is backed by Mr. Moore, Mr. Hugh

HARTE, Mr. LONSDALE, and Captain CRAIG. The first clause of the Bill sets forth that it is the duty of local authorities to enable blind and deaf children resident within their area to obtain elementary education in some school which for the time being is certified by the Commissioners of National Education as suitable for providing such education to them. In the second clause powers are conferred on the local authority to make arrangements for ascertaining what children within its area are defective or epileptic. For the purpose of ascertaining whether a child is defective or epileptic within the scope of the measure a certificate to that effect by a duly qualified medical practitioner approved of by the Commissioners of National Education shall be required in each case. In the next clause power is given to the local authority to obtain elementary education for defective and epileptic children in some school certified by the Commissioners as suitable for the purpose.

HOUSE OF COMMONS.

WEDNESDAY, MARCH 20TH.

The Education (Scotland) Bill.

Mr. SEXTON, the Secretary for Scotland, in introducing the Education (Scotland) Bill said that amongst its various purposes the Bill provided for the medical examination and supervision of pupils at the option of the School Board or where special circumstances existed at the option of the Education Department. There was power in the Bill to do all that was necessary in the way of providing the necessary machinery for the provision of meals for school children. A clause of the Bill dealt with what might be termed neglected children. In these cases it was provided that where as the result of medical inspection or otherwise it was brought to the knowledge of the School Board that a child was neglected or was in a filthy or venereal condition, or ill clad, or ill fed it should be the duty of the School Board to make inquiry as to the reasons for his condition. If the parent appeared to be at fault he was to be prosecuted as for cruelty to children and provision made for the child accordingly. If the parent was unable, by reason of poverty or ill health, to do his duty by the child the case was to be referred to the parish council, but help given by the parish council for this purpose would impose no disability on the parent. The School Board had the power in the meantime, and so long as might be necessary pending inquiry, to make provision for the child out of school funds.

Sir HENRY CRAIG, in the course of a criticism on various points in the Bill, said that he was glad to see that it made provision for some medical care of the children in the schools. He pointed out that a Bill for the provision of meals for school children had already been introduced into the House by the Labour Members. That Bill threw the financial onus on the School Board, but the Bill of the right honourable gentleman threw it on the parish council. There was a fundamental distinction between the two principles. Which was the Government prepared to follow?

The Bill was introduced and read a first time.

The Ennis State Inebriate Reformatory.

Mr. WILLIAM REDMOND asked the Chief Secretary to the Lord Lieutenant of Ireland how many men and how many women had been committed to the Ennis State Inebriate Reformatory since its establishment; and whether he could estimate how many of these had been considered cured of drunkenness on discharge; and whether he would direct the special attention of the judicial authorities in Ireland to the advisability of sending persons convicted of offences arising from drunkenness to this reformatory instead of to prison.—Mr. BIRRELL (by written answer) replied: Since the establishment of Ennis State Inebriate Reformatory in 1899 33 men and 63 women have been committed, of whom 29 men and 62 women have been discharged. Each case is watched and reported on periodically after discharge. Of the 29 men discharged, 16 are reported cured, 3 are dead, and 10 have relapsed. Of the 62 women discharged, 21 are reported cured, 5 are relapsed, 2 are in lunatic asylums, and 24 have relapsed. The question of sending persons to the Inebriate reformatory is one entirely for the judicial authorities themselves. I will, however, bring the honourable Member's suggestion to the notice of the Lord Chancellor.

FRIDAY, MARCH 22ND.

Owing to the fact that the sitting of Wednesday was prolonged into Thursday afternoon no questions were taken on the latter date. However, on Friday Ministers circulated the replies which in normal circumstances they would have made in the House on Thursday. Some of these are included among the following questions.

Dangerous and Criminal Lunatics.

Major AMSTRUTHER-GRAY addressed the following three questions to the Lord the subject of dangerous and criminal lunatics in Scotland to the Lord Advocate: (1) whether a dangerous patient in a district lunatic asylum might be discharged and handed over to relatives relieved but not cured; and, in that case, whether the lunacy authorities had no further charge or responsibility; (2) whether he would consider the advisability of taking the necessary steps to insure that all cases of dangerous lunatics who had committed assault resulting in loss of life should be dealt with in a criminal lunatic asylum, instead of relegating them to a district asylum; and (3) whether, seeing that the presence of criminal lunatics who had committed murder was detrimental to the general freedom from severe discipline in district asylums, the beneficial effect of what was termed the "pan-door" system being acknowledged, he would take the necessary steps to keep the district asylums free from criminal lunatics who had committed murder or attempted murder, as far as possible.—Mr. SIMON (who sent a written answer on behalf of the Lord Advocate) said: The question raised by the honourable Member is under inquiry and I must ask him to recur to the matter at a later date when I shall endeavour to answer his questions.

Typhus Fever in County Galway.

Mr. O'MALLEY asked the Chief Secretary to the Lord Lieutenant of Ireland whether his attention had been called to the fact that typhus fever had broken out in Oughterard, county Galway; that three deaths

Notes, Short Comments, and Answers to Correspondents.

A RETIRED MEDICAL MAN AND GOOD OPENINGS.

On the issue of THE LANCET of March 16th the following two little advertisements appeared:—

Wanted to purchase immediately, small PRACTICE in rising neighbourhood. Large, lowly rented house a necessity.—Address, No. 368, THE LANCET Office, 423, Strand, W.C.

For Sale, Nucleus of good-class Practice in excellent neighbourhood. Premium low.—Address, No. 369, THE LANCET Office, 423, Strand, W.C.

Among the replies received by the first advertiser, No. 368, was the following:—

COPY.

8, Stone St.

FAVERSHAM, Kent.

March 15, 1907.

Private & confidential.

In reply mention No. 368.

Dear Sir,

I can introduce you to some good openings for making a start in practice where you would be able to pay expenses from the beginning and make a good practice. They are situated in localities unopposed or where further medical help is required. If you like to give me a call here I can lay the cases before you

Watering-Place

Premium £100,

150 miles from London. One doctor doing £2300 a year, and his assistant carrying on branch 5 miles away, but on the coast, doing £800 a year. A good man starting in the latter place would get it all the £800 in a year I am told by a medical friend. These are the only two doctors in these places.

Kent, premium £50, 20 miles from Town beautifully situated, pop 7000 and only 2 doctors, (partners) & 3 doctors only to 14,000. A fine chance, as extensive works are about to commence employing thousands of hands, houses with stables and gardens to let at £40, £45, £50 & £55 now vacant. Bracing, gravel soil, High Ground.

Kent, £50 premium, Best part of hop and fruit district, very good opening

Bucks £30, & a similar premium for openings in Herts, Hants, Oxon, Essex, Staffs, and Surrey.

I can give some introduction to all.

Yrs faithfully,

P. F. JAY, M.D.

To the second advertisement, numbered 369, a reply was sent upon a postcard in the same handwriting as the letter printed above, dated from 8, Stone-street, Faversham, Kent, and bearing the Faversham post-mark. The postcard ran as follows:—

COPY.

Dr. Betts will be glad to receive full particulars in the strictest confidence.

March 15, '07.

We suggest that the information which Dr. Jay proposes to sell to advertisers like No. 368, who wants to purchase a practice, is obtained from advertisers like No. 369 who wants to sell one. It is obvious that the result of Dr. Jay's intervention might be as follows. He could find out from No. 369 why he was anxious to leave his present position and obtain from him all the information tending to make that position covetable. He could then write to No. 368 and offer him information concerning an opening in return for a fee. He need have no other information about the practice to assume that it is a "good opening" and might easily lead No. 368 to purchase a business of no value. To ask money from a man for such a service is well, let us say enterprising. But suppose Dr. Jay brings the practice of No. 369 to the notice of No. 368 as a business in a place where a medical man could set up for himself without going through the formality of purchase he would pocket a fee himself, while much damaging No. 368's chance of obtaining a purchaser.

We ask our advertisers to help us to stop such methods of business and to do this in their own defence. For the future no letters or post-cards will be forwarded to them from this office which we can tell emanate from Dr. Jay, but by the assumption of pseudonyms, by getting assistance in the directing of envelopes, by posting his replies elsewhere than in Faversham, and so on, he can easily elude our vigilance. In case advertisers do obtain offers of assistance from Dr. Jay we strongly advise them to make no reply, at any rate, to pay no money. Either as buyer or as seller they may be placed at a grave disadvantage in dealings carried on by such intervention, and it is not worth while to pay a fee for such services to any man, even though he be a professional brother.

THE MOTOR UNION AND THE CARS OF MEDICAL MEN.

The Motor Union of Great Britain and Ireland is contributing towards the legal expenses of an important case which raises a question of great interest to medical men using motor-cars throughout the country—namely, whether they are to be charged a water rate as

in the case of business vehicles, when they use their cars partly for professional purposes. The case was taken up at the instance of the Harrogate Automobile Club on behalf of one of its members who is also a member of the Motor Union. The member was sued at the Knaresborough Petty Sessions by the Harrogate Corporation for the recovery of 10s., being a half-year's rate levied in respect of water for his car, which he refused to pay. Mr. J. R. A. Tittley, the Motor Union local solicitor, submitted for the defendant that the corporation could not possibly, under the Act, ask him to pay for water for washing his car for "trade" purposes, that being the provision of the Act under which he was charged. The bench adopted this view and also decided against the contention of the town clerk that there was an implied contract because the defendant had paid on two previous occasions. The bench agreed, at the request of the town clerk, to state a case for the opinion of the High Court, and the Motor Union is assisting its member in order that the decision of the justices may be sustained. Any motorist who has had a similar difficulty with his water rate in the matter of special charges in respect of motor-cars should communicate with the secretary of the Motor Union at 1, Albemarle street, London, W.

WHAT IS PLASTICINE?

To the Editors of THE LANCET.

SIR,—Will you kindly allow me to answer your correspondent "London's" question, "What is plasticine made and coloured with?" Not a single ingredient enters into plasticine, composition and colouring matter, but what people are in the habit of using as food and swallowing every day, such things as sulphur, farina, a vegetable oil, vaseline—the colouring matter being absolutely harmless, no arsenic, copper, lead, or other deleterious substance entering it. The material has been subjected to the most rigorous independent tests by hostile critics as against analyses by experts employed by myself, and in the case of such educational authorities as the late London School Board, the Board of Education for New York, the Incorporated Institute of Hygiene, and other certified analysts, the claim for plasticine being an antiseptic and perfectly safe modelling material has been wholly conceded.

I might add further that of the hundreds of thousands of children now using plasticine there has never been an authenticated case of injury resulting, and of the scores of workpeople (including young girls and children) in my employ, who have been with me for many years engaged in the manufacture of plasticine, there has never been a case of injury, ailment, or epidemic whatever. The material has a wholly beneficial effect upon the skin and joints and has a healing influence upon burns, scalds, abrasions, and wherever the skin is broken. From very extended observations, and numerous reports from school teachers, I make the above statement without any qualification whatever.

My factory is open, by advertised invitation, to the inspection of the public, and many visitors to Bath avail themselves of it.

I am, Gentlemen, yours faithfully,

WM. HARBUTT.

P.S.—The success with which plasticine has met has called into existence worthless and objectionable foreign imitations, some made with clays and caustic potash and other irritant alkalies. I had to warn the public against these dangerous counterfeits last year. Your correspondent may have made acquaintance with one of these "substitutes" for plasticine.

POST HOC, ERGO PROPTER HOC.

In the course of his arguments in favour of teetotalism the lecturer chose to illustrate the harmlessness of water and the harmfulness of alcohol by placing an earth worm first in a glass of the former fluid and then in a glass of whisky. Of course, the worm showed a lively movement in the water, while in the whisky its activities apparently ceased for ever. At the close of the lecture the orator invited the audience to sign the pledge. One old lady pushing her way eagerly in front of others was heartily received and loudly exhorted to sign the pledge and to be a better woman. "No," she said, "I was not thinking about the pledge, I was just wondering where you got that whisky from as I have been suffering from worms for years."

THE PERCENTAGE OF SULPHUR IN FOODS.

M. Baland has published the results of his work on the determination of the amount of sulphur in various food materials (*Journal de Pharmacie et de Chimie*, Jan. 16th, p. 49). As in the case of the phosphorus determinations referred to in THE LANCET of March 2nd, p. 604, the tests were carried out on the fresh food materials and not, as is usually the case, on their ash. The following figures express the percentage of sulphur contained in the foods enumerated: wheat, maize, barley, and rye, 0.027 to 0.046; the percentage is slightly higher in oats and buckwheat. The following green vegetables were first dried in a stove: carrots, 0.092; lettuce, 0.214; turnips, 0.181; leeks, 0.397; and potatoes, 0.1. The percentage of sulphur in the ordinary dried beans, haricot beans, lentils, and peas of commerce varied from 0.032 to 0.18. Stone fruits, dried in a stove, were found to contain notable proportions of sulphur, apricots and strawberries containing from 0.012 to 0.021 per cent., and cherries and peaches from 0.1 to 0.114 per cent. of sulphur.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to THE LANCET Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week such information for gratuitous publication.

ALLEN, C. H., M.B., B.S. Edin., F.R.C.S. Edin., has been appointed Medical Officer to the Nottingham Board of Guardians.

COOKE, THOMAS ALFRED BURBARD, L.R.C.P. Lond., M.R.C.S., has been appointed District Medical Officer by the Pembroke Board of Guardians.

JOHNSON, JAMES BOVELL, M.D., C.M. Montreal, L.S.A. Lond., has been appointed District Medical Officer by the Sturminster (Dorset) Board of Guardians.

KING, WILLIAM WILFRED, L.R.C.P., M.R.C.S., has been appointed Resident Obstetric Officer at the Bristol Royal Infirmary.

SMITH, LIONEL SHINGLETON, L.R.C.P. Lond., M.R.C.S., has been appointed House Surgeon at the South Devon and East Cornwall Hospital, Plymouth.

TAYLOR, FRANK B., M.D., B.S. Lond., F.R.C.S. Eng., M.R.C.P. Lond., D.P.H. Cantab., has been appointed Physician for Diseases of Women to the North-West London Hospital and to the St. Mary-lebone General Dispensary.

TURNER, ARTHUR JOHN, M.B., B.S. Durh., has been appointed Junior House Surgeon at the Bristol Royal Infirmary.

WALTERS, CHARLES FERRIS, F.R.C.S. Eng., L.R.C.P. Lond., has been appointed Surgical Registrar to the Bristol Royal Infirmary.

WYATT, H. D., M.R.C.S., L.R.C.P. Lond., has been appointed House Physician at the Evelina Hospital for Sick Children, Southwark, S.E.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index)

BEDFORD COUNTY HOSPITAL.—Honorary Assistant Physician.

BIRKENHEAD UNION INFIRMARY AND SANATORIUM.—Resident Assistant Medical Officer. Salary £120 per annum, with board, washing, and apartments.

BIRMINGHAM, QUEEN'S HOSPITAL.—Second Physician for Out-patients and Pathologist. Salary £100 per annum.

BIRMINGHAM, UNIVERSITY OF.—Demonstratorship in Anatomy. Stipend £150 per annum. Also Junior Assistant, Pathological Department. Salary £50 per annum.

BIRMINGHAM WORKHOUSE INFIRMARY.—Assistant Resident Surgical Officer. Salary £104 per annum, with apartments, ration, attendance, &c.

BODMIN, CORNWALL COUNTY ASYLUM.—Third Assistant Medical Officer, unmarried. Salary £140 a year, rising to £160, with room, ration, laundry, and attendance.

BURY INFIRMARY.—Senior House Surgeon. Salary £110, with board, residence, and attendance.

CHICHESTER, WEST SUSSEX COUNTY ASYLUM AND GRAYLINGWELL MENTAL HOSPITAL.—Junior Assistant Medical Officer, unmarried.

MAIDSTONE, WEST KENT GENERAL HOSPITAL.—Assistant House Surgeon and Anaesthetist, unmarried. Salary £60, with board lodging, and washing.

METROPOLITAN HOSPITAL, Kingsland-road, N.E.—Dental Surgeon Also Medical Officer in Charge of the Electrical Department. Salary £52 10s. per annum.

MIDDLESBROUGH, NORTH RIDING INFIRMARY.—Assistant House Surgeon, unmarried. Salary £75 per year, with residence, board, and washing.

NEWPORT AND MONMOUTHSHIRE HOSPITAL.—Junior Resident Medical Officer. Salary £70 per annum, with board, residence, and laundry.

NORTHAMPTON GENERAL HOSPITAL.—Assistant House Surgeon. Salary £50 per annum, with apartments, board, washing, and attendance.

PADDINGTON GREEN CHILDREN'S HOSPITAL, London, W.—House Physician, also House Surgeon, for six months. Salary at rate of 50 guineas per annum, with board and residence.

PORTSMOUTH, ROYAL PORTSMOUTH HOSPITAL.—House Physician. Salary £50 per annum, with board, residence, and laundry.

ROYAL MAR HOSPITAL, Dean-street, Soho, W.—House Surgeon, non resident, for six months. Honorarium at rate of £40 per annum.

ROYAL SOUTH LONDON DISPENSARY.—Honorary Surgeon-Dentist.

SCARBOROUGH HOSPITAL AND DISPENSARY.—Junior House Surgeon. Salary £80 per annum, with board and residence.

SEAMEY'S HOSPITAL SOCIETY, Greenwich, S.E.—For DREADNOUTH HOSPITAL: Two House Physicians and Two House Surgeons. Salary in each case £50 per annum, with board, residence, and washing.—For BRANCH HOSPITAL, Royal Albert Dock, E.: Senior House Surgeon and Registrar, also House Surgeon. Salary a former £100 per annum, and of latter £50 per annum, with board residence, and washing.

STAFFORD, STAFFORDSHIRE GENERAL INFIRMARY.—Assistant House Surgeon. Salary £82 per annum, with board, residence, and laundry.

SUNDERLAND INFIRMARY.—House Surgeon. Salary £80 per annum with board, residence, and washing.

THORNTON HOSPITAL, Golden-square, W.—Assistant Surgeon.

WARRINGTON, LANCASHIRE COUNTY ASYLUM, Warrick.—Assistant Medical Officer, unmarried. Salary £150, rising to £200 with apartments, board, &c.

WEST BROMWICH DISTRICT HOSPITAL.—Resident Assistant House Surgeon, unmarried. Salary £50 per annum, with board, residence, and washing.

WEST LONDON HOSPITAL, Hammersmith-road, W.—Assistant Ophthalmic Surgeon.

WIMBORNE, DORSET COUNTY ASYLUM.—House Surgeon. Salary £65, rising to £75, with board, residence, &c. Also Honorary Physician in Ordinary.

WOLVERHAMPTON AND STAFFORDSHIRE GENERAL HOSPITAL.—Senior House Surgeon. Salary £100 per annum, with board, lodging, and laundry.

Births, Marriages, and Deaths.

BIRTHS.

HARDENBERG.—On March 25th, at Duffield House, Watford, the wife of E. F. H. Hardenberg, M.B., M.R.C.S., L.R.C.P., of a son.

PARKER.—On March 23rd, at Clonsilla, Kilnashin, Renfrewshire, the wife of James Parker, M.D., C.M., of a son.

TAYLOR.—On March 26th, at 35, Nicholas-street, Chester, the wife of J. G. Taylor, M.A., M.D., M.R.C.P., of a daughter.

DEATHS.

LEACH.—On March 11th, on the s.s. Argonaut, John Comyns Leach M.D., J.P., of The Lindens, Sturminster Newton, Dorset, aged 65 years.

ROSE.—On March 12th, suddenly, on P. and O. s.s. Navar, Dead Home, L.R.C.P., L.R.C.S. Edin., L.F.P.S. Glasg., aged 23 years.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

SOCIETIES.

WEDNESDAY (2nd).—OBSTETRICAL SOCIETY OF LONDON (20, Hanover-square, W.).—8 P.M.: Special General Meeting to receive the Report of the Council. Specimens will be shown by Dr. H. R. Andrews, Dr. Lewers, and Mr. J. H. Dauber. Paper:—Mr. J. D. Malcolm: On the Adviability of Removing the Cervix in performing Hysterectomy.

THURSDAY (3th).—NORTH-EAST LONDON CLINICAL SOCIETY (Tottenham Hospital, N.).—4 P.M.: Clinical Cases.

FRIDAY (5th).—WEST LONDON MEDICO-CHIRURGICAL SOCIETY.—8 P.M.: Clinical Evening.

LITHOLOGICAL SOCIETY OF LONDON (20, Hanover square, W.).—5 P.M. Exhibition of Cases and Specimens.

WEST-EAST MEDICO-CHIRURGICAL SOCIETY.—Discussion on the Necessity for Organisation in the Medical Profession (opened by Dr. F. S. Toogood).

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

TUESDAY (2nd).—POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.).—10 A.M.: Dr. Moulton: Gynaecological Operations. 2 P.M.: Medical and Surgical Clinics. X Rays. Dr. Ball: Diseases of the Throat, Nose, and Ear. 2.30 P.M.: Operations. Dr. Abraham: Diseases of the Skin.

NORTH-EAST LONDON POST-GRADUATE COLLEGE (Tottenham Hospital, N.).—Cliniques.—10.30 A.M.: Medical Out-patient (Dr. Auld). 2.30 P.M.: Gynaecological Out-patient (Dr. Giles), Surgical Out-patient (Mr. Edmunds). Surgical Operations (Mr. Carson).

WEDNESDAY (3rd).—POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.).—10 A.M.: Dr. Ball: Diseases of the Throat, Nose, and Ear. Dr. Sanders: Diseases of Children. 2 P.M.: Medical and Surgical Clinics. X Rays. 2.30 P.M.: Operations. Dr. Robinson: Diseases of Women.

NORTH-EAST LONDON POST-GRADUATE COLLEGE (Tottenham Hospital, N.).—Cliniques.—2.30 P.M.: Skin (Dr. Meachen), Eye (Mr. Brooks), Medical Out-patient (Dr. Whipple).

CENTRAL LONDON THROAT AND EAR HOSPITAL (Gray's Inn-road, W.C.1).—5 P.M.: Demonstration.—Mr. Stuart-Low: Middle Ear and Labyrinth.

THURSDAY (4th).—POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.).—2 P.M.: Medical and Surgical Clinics. X Rays. 2.30 P.M.: Operations.

NORTH-EAST LONDON POST-GRADUATE COLLEGE (Tottenham Hospital, N.).—2.30 P.M.: Demonstration on Fevers (Dr. P. Thomson at the North-Eastern Fever Hospital, St. Ann's-road, N.), Gynaecological Operations (Dr. Giles), Cliniques.—Medical Out-patient (Dr. Whiting), Surgical Out-patient (Mr. Carson). 3 P.M.: Medical In-patient (Dr. Chappell).

FRIDAY (5th).—POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.).—10 A.M.: Dr. Moulton: Gynaecological Operations. 2 P.M.: Medical and Surgical Clinics. Dr. Ball: Diseases of the Throat, Nose, and Ear. X Rays. 2.30 P.M.: Operations. Dr. Abraham: Diseases of the Skin.

NORTH-EAST LONDON POST-GRADUATE COLLEGE (Tottenham Hospital, N.).—9.30 A.M.: Cliniques.—Surgical Out-patient (Mr. H. Evans). 2.30 P.M.: Surgical Operations (Mr. Edmunds). Cliniques.—Medical Out-patient (Dr. Auld), Eye (Mr. Brooks). 3 P.M.: Medical In-patient (Dr. Leale).

SATURDAY (6th).—POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.).—10 A.M.: Dr. Ball: Diseases of the Throat, Nose and Ear. 2 P.M.: Medical and Surgical Clinics. X Rays. 2.30 P.M.: Operations. Dr. Robinson: Diseases of Women.

EDITORIAL NOTICES.

It is most important that communications relating to the Editorial business of THE LANCET should be addressed exclusively "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners. Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET should be addressed "To the Manager."

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.
TO SUBSCRIBERS.

Will Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.O., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and not to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will insure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 15 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.O.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates, on this or on any other ground, should be resisted. The Proprietors of THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues; and Agents are authorised to collect, and generally do so collect, from the Proprietors the cost of such extra postage.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied. Address—THE MANAGER, THE LANCET OFFICES, 423, STRAND, LONDON, ENGLAND.

METEOROLOGICAL READINGS.

(Taken daily at 3.30 a.m. by Steward's Instruments.)

During the week marked copies of the following newspapers have been received—Melbourne Argus, Scarborough Evening News, Standard, Cornish Times, Westminster Gazette, Liverpool Post, Manchester Guardian, Staffordshire Sentinel, Dublin Telegraph, Manchester Weekly Times, Glasgow Herald, Leeds Mercury, Daily Telegraph, Daily Chronicle, Gloucester Citizen, &c.

A FAMOUS ENGLISH SURGEON.

AN Australian correspondent has sent us a copy of the *Melbourne Argus*, dated Feb. 2nd, 1907, in which there appears a flaming advertisement of the Freeman and Wallace Electro-Medical Institutes under the above title. The institutes, we learn, cure "bladder diseases, kidney diseases, blood poison, lost vitality, varicocele, skin disorders, weakness, rupture, piles, &c.," and address themselves to "weak men" who desire to be "made strong," urging them to "get cured now," for "these diseases we cure. We care not who has failed to cure you." The title of the advertisement is explained by the fact that the institutes have secured the surgical services of "Dr. Kempster, M.R.C.S. Eng., L.R.C.P. Lond., M.S.A. London," of whom they say that he "is an expert in the rapid treatment and cure of men's diseases, and is late Civil Surgeon to the British War Office, London; late Medical Officer of Health, London (Battersea division); late Assistant Divisional Surgeon, London Police; and Deputy District Medical Officer to Wandsworth and Clapham Districts of London (which have an estimated population of half a million), and Fellow of the Incorporated Society of Medical Officers Health, London. Dr. Kempster's experience is large and valuable, and in the rapid treatment and cure of men's diseases, arising from any specific cause, or from exhaustion or heredity, he is an expert both in method and in scientific knowledge. His abilities are so rare and his knowledge of practical surgery so pre-eminent that he has been secured at an enormous salary by the principal of the Freeman and Wallace Electro-Medical Institutes of Melbourne and Sydney for the benefit of diseased and suffering men. Dr. Kempster has qualifications scarcely equalled by any operating surgeon in Australasia; his medical career in England has been distinguished by high achievements in conservative surgery. He is associated with Dr. Wallace, the Institutes Chief Physician, who may be consulted free by any man requiring the best medical advice possible to secure. Special appointments may be made."

Our correspondent inquires, "Is the gentleman being personated or has he really joined with this disreputable clique? Perhaps you will kindly try to throw a light upon the matter for us poor Australians." We have made inquiries, from which it appears possible that Kempster is still upon the Medical Register, though he should not be. He never was in the least respect a famous surgeon and his present occupation as a partner of quacks and a decoy for dupes does not surprise us.

APPARATUS FOR ELEVATING THE HIPS IN BED.

To the Editors of THE LANCET.

SIRS,—On p. 817 of THE LANCET of March 23rd are a picture and description of a new hip elevator made from the design of Dr. E. G. Gilbert. I would like to point out that four years ago (August 2nd, 1902) you published a picture and description of a similar apparatus identical in principle with the one figured in your present issue. In designing my "Sister Doria" bedrest I thought I was supplying a long-felt want, and having proved its comfort and also its capacity for carrying out all that is claimed for it—i.e., the prevention of slipping down in the bed—I am the more surprised that it is not generally known and in more general use.

I am, Sirs, yours faithfully,
Richmond, March 26th, 1907. GEORGE W. ORD.

P.S.—I might call attention to the fact that Messrs. Allen and Hanbury registered the "Sister Doria."

* * Mr. Ord is correct in his facts. But, after all, both devices are only the obvious outcome of the old household method of keeping the patient up by a small chair, placed in the bed, so that it rests on the front edge of the seat and the front of "the back."—ED. L.

A SELF-FILLING FOUNTAIN PEN.

A VERY large proportion of the persons engaged in the professional and commercial worlds now use a fountain pen of some sort, carrying it with them as regularly as they do their watch, so that it is not surprising that the market offers a large choice of such contrivances or that new inventions claiming various advantages are frequently in evidence. The fountain pen has unquestionably been improved in detail. We do not call to mind that any pen other than the "Conklin" has been improved in the direction of doing away with the accustomed method of replenishing the supply of ink by means of the glass dropper with its indiarubber teat. The Conklin Pen Co., through American Agencies, Limited, 38, Shoe-lane, London, E.C., have submitted to us the "Conklin" pen, for which no filler is required; the interior of the pen is, in fact, the filler and the reservoir for the ink. The operation for filling the pen is simple. Give a collar in the middle of the pen a quarter turn, place the point of the pen in a receptacle containing ink, press a crescent-shaped piece of steel over the collar, and the pen is filled. Turn back the collar and the reservoir is closed. In our hands the pen performed its mechanical duty admirably and also has proved a good instrument to work with.

THE VENTILATION OF HATS: AN EXPERIMENT.

WE have received from the Patent Padded Hat Co., of Bradford-on-Avon, a specimen of a "ventilated" hat, in which a simple but perhaps new idea is developed. The hat is of the common shape known as a "bowler" (Amer. "Derby," Canad. "Christie," Fr. *Melon*), though

many dictionaries apparently refuse to recognise the word. The internal leather band of the hat has sewn on to it six small pieces of thin leather about one and a half inches square, arranged in intervals around the band, and each piece incloses a pad of soft felt. The hat, which is perforated in the crown, has no lining but in other respects, such as in the band, brim, and binding, it is similar to the usual type of bowler. There is ample room for ventilation all round the head, a free passage of air being permitted between the ventilation in the crown and the air spaces next the skull. There is no doubt that hats should be properly ventilated and they should not fit so tightly as to leave a mark or ridge on the forehead, for this means interference with the nutrition of the scalp. But the general public is rather conservative in such matters. It has got on till now with a hat fitting the head, and whether it will appreciate the endeavour to convert it to the "ventilated" hat we do not attempt to guess. The idea, however, is a sound one, and may be quite novel but has not something like it been adopted in the construction of pith helmets?

BRITISH MEDICAL BENEVOLENT FUND.

To the Editors of THE LANCET.

SIRS,—I shall be grateful to anyone who has clothing for men, women, or children to spare for distribution to distressed members of the profession or their families if they will send such articles of clothing to the address given below, where I will receive and send them on as I have done hitherto.—I am, Sirs, yours faithfully,

EDWARD HART.

24, Randolph Crescent, Malda Hill, W., March 11th, 1907.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

The Hunterian Lectures

ON

THE PATHOLOGY OF MELANOTIC GROWTHS IN RELATION TO THEIR OPERATIVE TREATMENT.

*Delivered before the Royal College of Surgeons of England on
Feb. 25th and 27th, 1907.*

By W. SAMPSON HANDLEY, M.S. LOND.,
F.R.C.S. ENG.,

HUNTERIAN PROFESSOR; ASSISTANT SURGEON TO THE
MIDDLESEX HOSPITAL.

LECTURE I.

Delivered on Feb. 25th.

MR. PRESIDENT AND GENTLEMEN,—The subject of these lectures attracted me on account of the very unfavourable results of operation in melanotic growths, and the belief that these results are capable of improvement is my principal excuse for claiming your attention. I shall deal almost exclusively with those pigmented growths which arise in the skin. My work on the subject was mainly carried out in the Middlesex Hospital Cancer Research Laboratories during my tenure of the "Richard Hollins" Cancer Research Scholarship. To the Cancer Investigation Committee and to the director of the laboratories, Dr. W. S. Lazarus-Barlow, my best thanks are due for the facilities afforded me and for permission to reproduce certain illustrations from the Archives of the Middlesex Hospital.

Many scientific men have held that the pursuit of useful knowledge, as distinct from the pursuit of knowledge for its own sake, degrades both the research and the student below the level of serious consideration. If that is really the case I must confess my unworthiness of the honour which this College has bestowed upon me, an honour which I would here gratefully acknowledge. But the utilitarian aim which is frankly avowed in the title of my lectures hardly needs a defence before an audience in daily contact with the pitiable urgent problems of cancer in the individual.

I have one other object in view. Two years ago I had the privilege of laying before you certain observations on the dissemination of carcinoma, observations which proved that the obscure and insidious process of permeation—the growth of tendril-like cylinders of cancer cells along the finer lymphatics which surround the primary growth—is the main factor in the dissemination of cancer of the breast. On the present occasion I propose to lay before you the results of parallel observations on melanotic sarcoma and to compare and contrast the mode of spread of these two varieties of growth. Only by the separate study of each variety of growth, a long and laborious task, can the element of theory and of unsafe analogy be eliminated from our knowledge of dissemination and from surgical practice. In my opinion, no more urgent piece of work, and none more certain of immediate result, confronts those who are investigating cancer. In this connexion the valuable work of Mr. G. Lenthal Cheatle upon the spread of squamous carcinoma of the tongue and lip, and that of Mr. C. H. Leaf and of Mr. J. F. Dobson upon lymphatic anatomy, deserve more than a passing mention.

The scope of morbid anatomy is by no means restricted to the revelation of details of structure. Its newer methods are capable of throwing light on the physiological problems of cancer and of indicating promising lines of experiment. In illustration of this statement I may be permitted to remind you that the destructive action of the blood on cancer cells, which was demonstrated by M. B. Schmidt in the pulmonary arterioles, and which I inferred independently three years ago from a study of metastatic distribution in the cancer research laboratories of the Middlesex Hospital, has received experimental confirmation in recent work on the prevention and treatment of mouse cancer, both in the laboratories of the Imperial Research Fund¹ and in America.² To you, Sir, who are so closely connected with both the institutions I have mentioned it must be a source of pleasure to see their work thus converging from opposite

sides upon the same problem. Experimental work and morbid anatomy are the two eyes of cancer research, and to deny the use of either is to forfeit the advantages of binocular vision.

For the sake of convenience it is necessary to depart from the logical order of my subject and to reserve for my second lecture certain problems as to the etiology and nature of malignant melanotic growths and the consideration of their surgical treatment. The present lecture will be concerned with a study of their mode of spread, chiefly based upon the following case.

ABSTRACT OF NECROPSY.

Necropsy No. 186, the Middlesex Hospital, 1905. The body is that of an emaciated woman, aged 34 years. At the insertion of the right tendo Achillis is a small healthy linear scar, where the primary melanotic sarcoma was excised. In Scarpa's triangle on the right side is a considerable mass in the situation of the femoral glands. Beneath the skin over and around this mass are very numerous discrete black nodular growths, occupying an area roughly circular in shape and perhaps eight inches in diameter. (See Fig. 1.) The growths become smaller in all directions the further they are situated from the femoral glands, until apparently healthy skin is reached. On the back, at the level of the tenth dorsal vertebra, there is a patch three inches square studded with similar cutaneous growths. The right breast shows enormous enlargement, and in the skin over the breast are many similar growths. The left breast, though smaller, is in a like condition. Scattered over the front of the thorax and the abdomen are numerous subcutaneous nodules, and there is one on the face in the left malar region. There is far more growth on the right side of the body than on the left. No deposits are present in the skin and subcutaneous tissue of the left leg below the level of the symphysis pubis. There are numerous deposits in the calvaria; a few small nodules are present in the brain and in the thyroid body. Several deposits are found on the posterior surface of the sternum. The cardiac muscle contains numerous nodules and a few are scattered throughout the lungs. The liver weighed 10½ ounces. The only abdominal viscera free from new growth are the spleen, ureters, bladder, and stomach. Numerous nodules are pendent from the mucosa of the intestines. The left femur shows a fracture one inch below the great trochanter, surrounded by a mass of non-pigmented new growth. All the muscles examined show minute specks of melanotic pigment. As regards the lymphatic glands, growth is found in the right femoral and internal iliac glands (and to a less extent in the lumbar glands) and in the cervical and axillary glands on both sides. For the investigation of lymphatic spread in this case it was natural to choose the tissues in the neighbourhood of the largest mass of lymphatic glands—that is to say, the tissues of the right groin. A strip of the parietal tissues passing down the thigh from this mass of glands was removed for examination. It measured 17 cm. in length, and extended from the lower edge of the mass of growth which occupied the situation of the inguinal glands vertically down the anterior surface of the thigh to a point about three inches above the knee. It traversed and passed well below the circum-inguinal area of visible subcutaneous nodules of growth (see Fig. 1). The strip included skin, subcutaneous fat, deep fascia, and a thin layer of muscle. It was frozen and subdivided longitudinally into three thinner strips. One of these was submitted to microscopic examination, while the two other strips, each about three millimeters thick, were mounted as naked-eye specimens.

METHOD OF PREPARATION.

The strips were prepared by a modification of a method which I first employed in 1904 for demonstrating carcinomatous nodules in the parietal tissues in cases of breast cancer. For this purpose long strips of the skin and subjacent parietal tissues radiating in any selected direction from the primary growth were cut from the cadaver and were subsequently stained and rendered translucent. The staining method employed had the defect common to all stains, that it is not specific for cancerous tissues. Moreover, time has shown that the specimens, when mounted in xylol for preservation in a museum, undergo continuous shrinkage and lose their purity of colour, so that after the lapse of two years their deterioration is marked. Melanotic sarcoma offers an ideal field for the application of this method in a simplified form, because the

An original and novel feature of "THE LANCET General Advertiser" is a Special Index to Advertisements on pages 2 and 4, which not only affords a ready means of finding any notice but is in itself an additional advertisement.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Answers are now received at this Office, by special arrangement, to advertisements appearing in THE LANCET.

The Manager cannot hold himself responsible for the return of testimonials, &c., sent to the Office in reply to Advertisements; copies only should be forwarded.

Cheque and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Office, 423, Strand, London, to whom all letters relating to Advertisements or Subscriptions should be addressed.

THE LANCET can be obtained at all Messrs. W. H. Smith and Son's and other Railway Bookstalls throughout the United Kingdom. Advertisements are also received by them and all other Advertising Agents.

Agent for the Advertisement Department in France.—J. ASTIER, 31, Rue Bapts, Asnières, Paris.

Battle has also described a case in which it occurred. At the risk of being tedious, I must remind you that my investigations on the spread of permeation in breast-cancer³ showed

FIG. 3.

An artery filled by melanotic growth from the proximal end of Fig. 2.

three zones surrounding the primary growth. Farthest from it is the zone of fascial permeation, where the permeated fascial lymphatic plexus forms the "microscopic growing edge" of the carcinoma. Here there is no interstitial invasion of the tissues; the cancer cells are found only in the interior of the lymphatic vessels and they occur exclusively in the plane of the deep fascia, while the overlying skin and the underlying muscle are normal. Within this region is a zone, in which an inflammatory reaction (perilymphatic leucocytosis and fibrosis) has been set up owing to the distension and rupture of the lymphatics by the growing cancer cells which they contain. In this zone cancer cells are seen spreading along the fine tributary lymphatics upwards towards the skin and downwards into the muscles and originating nodular metastases in the lymphatic capillary areas of these layers. Nearest to the primary growth comes a third zone in which all or most of the permeated lymphatics, strangled by their newly-formed envelope of fibrous tissue, have entirely disappeared. Consequently, in this region the only cancerous foci are isolated nodules, becoming larger and invading the tissues to an increasing depth until the primary growth is reached.

Now the process of permeation is largely a mechanical one and its spread around a given focus is chiefly determined, like that of an injection fluid, along the line of least resistance. If melanotic sarcoma spreads by permeation one would expect that, round the original focus of growth, the same three zones would be present. In this specimen (Fig. 2) each of them is, I think, clearly indicated. Here is the zone of fascial permeation, represented by small black dots and lines upon and just over the deep fascia. The skin and the muscles in this region are quite free from growth. The minuteness of the black lines indicates that the lymphatics have been recently invaded and that they have not yet been distended or ruptured by the growth within them. Somewhat nearer the primary growth, the coarseness of the lines upon the deep fascia indicates rupture of the lymphatics and small nodules are seen in course of formation over and under the deep fascia. The

skin is not yet attacked, but arcorescent lines of growth are seen running up to it from below. Yet a little nearer the proximal end of the strip the growth has reached and filled up the convergent bundles formed on the under aspect of the dermis by the lymphatics draining the skin into the underlying fascial plexus. Here, too, is seen the first indication of perilymphatic fibrosis—the process which destroys permeated lymphatics—for some of the black lines are vague and moniliform.

We now come to the zone nearest the original focus—the zone of isolated nodules. You will notice the disappearance from the deep fascia of the lines and dots which indicate fascial permeation. But the large nodules which now make their appearance in the various layers are not isolated as in breast-cancer. A network of coarse black lines is still present. This network indicates two fundamental differences between the mode of spread of breast-cancer and that of melanotic sarcoma. First, in melanotic sarcoma the process of perilymphatic fibrosis is only very partially successful in destroying the permeated lymphatics. Secondly, in melanotic sarcoma, as I shall be able to show, blood-vessels are frequently invaded from contiguous permeated lymphatics. The network of coarse black lines at the proximal end of the strip largely consists, not of permeated lymphatics, but of blood-vessels filled by growth.

MICROSCOPIC EXAMINATION OF THE STRIP.

I have now to prove the correctness of the explanation which I have suggested for the appearances seen in the naked-eye specimen. A strip parallel to and adjoining the one which I have just described was divided into nine blocks and examined histologically along its whole length. It would be tedious to plunge into the sea of detail presented by a microscopic section 17 centimetres in length, and I shall briefly summarise the appearances met with in each of the nine blocks, commencing at the end close to the massive gland deposits and travelling radially away from them. A gradual and regular change will be noted as the strip passes

FIG. 4.

× 50. From the proximal end of the strip near the mass of growth which represented the inguinal glands, shows a cylindrical cord of melanotic growth lying unencapsuled in the perivascular tissues and replacing the concomitant venous and lymphatic vessels. D is the artery, C a small vein containing a cylinder of dense growth infiltrated by leucocytes. The circle B shows the situation of Fig. 3.

³ Cancer of the Breast and its Operative Treatment, by W. Sampson Handley. Murray, 1906.

specimens can be mounted in an absolutely unstained condition. The dark colouration of this particular variety of growth is the equivalent of a specific stain for malignant tissues, a desideratum which is at present lacking in the case of other growths. The two strips having been frozen and cut were placed in methylated spirit for 12 hours, and subsequently in acetone for a similar period; they were thence transferred to xylol for a few hours, and finally mounted in liquid paraffin (parolein) as museum specimens in flat-sided jars.

The use of acetone as a dehydrating agent in place of absolute alcohol was suggested to me by Dr. Victor Bonney, while the employment of liquid paraffin as a mounting fluid is an improvement due to Mr. Cecil W. Rowntree. In contrast to xylol liquid paraffin is not appreciably volatile; moreover, it is perfectly transparent and tends to make the specimen soft and pliable rather than to harden it. The only remaining doubt, whether it ultimately exercises any deleterious action on the specimen or is itself discoloured by the action of light, can only be settled by the lapse of time.

FIG. 1.

Showing all the visible subcutaneous nodules of melanotic growth present in the anterior aspect of the body, except one on the face. The dotted line A B shows the position and extent of the strip of tissue removed for examination. The dotted circles in the mammary region represent prominent masses of secondary growth in the breasts. Note that the growth was on the right heel and that most of the secondary nodules are situated on the right side of the body.

NAKED-EYE DESCRIPTION OF THE STRIP.

At the end nearest the inguinal glands the subcutaneous tissue is not transparent, but has a ground-glass appearance resembling that of the cornea in keratitis. Further away, towards its distal end, the fatty subcutaneous tissue has cleared perfectly and is quite transparent. As will be seen later the cloudiness of the tissues at the proximal end of the strip is due to round-celled infiltration and fibrous tissue formation; in other words, to the inflammatory reaction which, as I showed in the case of breast-cancer, accompanies the later stages of permeation. The melanotic foci present in the strip stand out in vivid contrast to the normal tissues as black blotches, sinuous lines, and dots (Fig. 2). The blotches represent spherical nodules, while the lines and dots quite clearly represent vessels lying in the plane of the strip or cut transversely as they penetrate it at right angles. The question at once arises, Are these vessels blood-vessels or lymphatics? Evidently the naked-eye appearances must be interpreted by the aid of the microscope, and the question must be for the present reserved.

The next point to notice is that the growth is not invading the tissues in the form of isolated embolic foci scattered at random here and there in the vessels; it is growing along the vessels and choking them up. At various points vessels filled by growth can be traced for some distance along the strip, giving off at intervals smaller branches, which also are

full of black material. Besides, the regular distribution of the black lines and dots indicates a complete injection of one or both of the vascular systems, spreading from the glands centrifugally, just as an artificial injection-fluid would spread from its point of introduction.

FIG. 2.

Reproduction of drawing, natural size, of a translucent strip of the skin and underlying tissues taken in a radial direction from the mass of growth. In this situation of the inguinal glands to demonstrate the centrifugal spread of permeation. Note that the growth extends much further along the deep fascia than along the skin or in the muscle. A, Skin. B, Subcutaneous fat, separated by the deep fascia from C, a thin layer of muscle.

I will ask you to assume, in anticipation of the microscopic proof, that this process is primarily one of lymphatic permeation. The occurrence in melanotic sarcoma of actual growth along the lymphatics seems to have been first observed and described, though not systematically investigated, by Campbell de Morgan at the Middlesex Hospital. Mr. W. H.

LOCAL DISSEMINATION AROUND THE RIGHT INGUINAL GLANDS.

The spread of subcutaneous nodules in all directions from the invaded mass of inguinal glands (see Fig. 1) indicates the working of a process of local centrifugal spread from point to point around these glands. The nature of this process is made clear by the microscopic findings which are just been described. Its various stages, from the most advanced to the earliest, are seen successively as the selected radial section is traced outwards from the centre of the mass

FIG. 7

Block 5, close to the deep fascia, 3 obj., No. 8 oc. A normal artery and vein are accompanied by two microscopic cords of growth, which doubtless represent their comitant lymphatics. To show that lymphatic invasion precedes invasion of the blood-vessels. Cf. Fig. 6.

of glands. Since the strip was taken down the limb and therefore against the flow of lymph the force of the lymph stream can have taken no share in this process of local centrifugal dissemination, at any rate, in the particular radial section examined.

It is obvious, both from Fig. 2 and from the microscopic sections, that the process is one of continuous growth of sarcoma along the vessels. And since towards the distal end of the strip only the lymphatic vessels are invaded and the blood-vessels are normal it is clear that lymphatic permeation is the initial process in the local centrifugal dissemination which we are discussing and that invasion of the blood-vessels—present only at the proximal end of the strip—is a secondary consequence in point of time, though not in point of importance.

INVASION OF BLOOD-VESSELS FROM COMITANT PERMEATED LYMPHATICS.

The tendency of melanotic sarcoma to spread along the perivascular tissues immediately outside the blood-vessels has been noticed by Borst. His explanation of the fact is a teleological one—namely, that blood is a necessary food for the production of melanin and that consequently the sarcoma cells are attracted towards the blood-vessels by a kind of chemotaxis. The true explanation appears to be a simple anatomical fact. The lymphatic vessels along which permeation extends usually run in company with arteries and veins.

Figs. 3 to 8 show the various events which lead to the invasion first of veins and later of arteries from comitant permeated lymphatics. Figs. 6 and 7 show two permeated lymphatics lying near normal blood-vessels. Fig. 5 shows the rupture of permeated lymphatics and the proliferation of the sarcoma cells around the walls of the accompanying artery and vein. In Fig. 4 the vein has been infiltrated and destroyed by sarcoma and portions of its muscular wall are imbedded in a cord of growth which accompanies the artery. The artery itself remains intact. The last stage of the process is demonstrated in Fig. 3, where an artery filled by growth can be seen. These observations are parallel to those of Goldmann and Schmidt on the invasion of veins from lymphatics in carcinoma.

THE QUESTION OF SPREAD ALONG THE SKIN.

A glance at Fig. 2 shows that the skin is not invaded nearly so widely as the deep fascia. As in carcinoma of the breast, the question arises how invasion of the skin occurs. Does the growth spread along the hypothetical "deep

cutaneous" lymphatic plexus at the junction of the dermis with the subcutaneous fat, as was formerly assumed to be the case in breast-cancer? Between points situated 10 and 12 centimetres along the strip a definite meshwork of black lines in this place can be seen (Fig. 2) and a superficial glance suggests that this network is the permeated "deep cutaneous plexus," and that the growth is in fact spreading slowly in this plane as well as in the plane of the deep fascia.

Closer inspection shows the error of the supposition. Just beyond the furthest point of invasion of the skin the growth is seen creeping up to the skin from below, against the lymph stream, along the vertical tributaries which convey lymph from the skin to the lymphatic plexus of the deep fascia. The fallacious appearance of a permeated deep cutaneous plexus is evidently only a further stage of this process. As Sappey showed, the lymphatic vessels coming from the skin, though they freely interlace, do not form a true plexus at the deep aspect of the dermis. They simply interlace like the entangled boughs of adjacent trees in a thick wood. The only cutaneous lymphatic plexus is the sub-papillary plexus. As in carcinoma, the layers adjoining the plane of the main (deep fascial) lymphatic plexus, are attacked by the upstream extension of permeation along the tributary lymphatics of the fascial plexus.

FIG. 8.

The fascia lata crosses the field vertically. To the left is the subcutaneous fat, to the right the surface of the muscle. Small permeated lymphatics and one large one, which has ruptured, are seen upon the surface of the fascia. In the subcutaneous fat normal blood-vessels are visible accompanied by permeated lymphatics.

REGRESSIVE CHANGES IN MELANOTIC SARCOMA.

The abundant round-celled infiltration present at the proximal end of the strip and the absence from this region of a network of small permeated lymphatics, are clear indications that reparatory processes, inadequate for cure, are not wanting in melanotic sarcoma. Borst has already drawn attention to these regressive processes. Lymphatics and veins invaded by the growth may undergo destruction (if

under review. Briefly speaking, at the proximal end of the strip there is invasion of the arteries and veins, with much round-celled infiltration round the extra-vascular nodules which are present. Towards the distal end no invaded blood-vessels are to be seen, but the lymphatics are filled by fine cylinders of growth. Here there is little evidence of inflammatory reaction and hardly any interstitial invasion of the tissues.

Block 1 shows invasion of arteries and veins, but no reticulum of small permeated lymphatics. Many large nodules are present. Only one cord of growth is present on the deep fascia, probably a large permeated lymphatic which has escaped obliteration. In the subcutaneous tissue is an artery of some size, not accompanied by a vein, filled by degenerate growth (Fig. 3). There is fibrosis of the peri-arterial tissues, which contain here and there granules of pigment and recognisable tumour cells. Deeper down is a normal artery, accompanied by a cord of growth (Fig. 4) which certainly represents its comitant vein, for in it can be seen imbedded remains of muscular tissue. This cord probably replaces also the comitant lymphatics of the artery in question. Some very minute foci of obsolescent growth are present along the fibrous septa which join the skin to the deep fascia. These septa are littered with fine granules of melanotic pigment. As regards the skin, its invasion is not uniform but has occurred at points where the fibrous septa join it. The terminal subdermal expansions of these fibrous septa are densely infiltrated by sarcoma cells.

Block 2.—Save that no artery filled by growth is present the appearances are similar to those seen in Block 1.

Block 3 presents appearances like those in Blocks 1 and 2. It shows an artery filled by growth, the muscular coat of which is infiltrated in its whole thickness by sarcoma cells. Outside the artery are a few recognisable sarcoma cells mixed with round-celled infiltration. The view suggests itself that the artery has been invaded from an adjoining permeated lymphatic which has subsequently undergone fibrosis. A new phenomenon makes its appearance in this block. At various points along the fibrous septa are seen

relatively large thin-walled vessels lined by endothelium. Almost certainly they represent distended lymphatics.

Block 4.—Nodular invasion of the skin has ceased. It

FIG. 6.

Normal blood-vessels accompanied by two lymphatics full of melanotic growth. From the zone of fascial permeation towards the distal end of Fig. 2. Photograph by the Pathological Laboratory, Mortimer-street, W.

FIG. 5.

Block 3, close to the deep fascia. 1 in. obj. No. 3 oc. At this point the growth has permeated the lymphatics and is infiltrating the tissues around but has not yet penetrated to the interior of the blood-vessels. A is an artery, B a vein, both normal. C is an endothelium-lined space (lymphatic), permeated by growth which has burst through its walls. D is a permeated lymphatic the wall of which is still unruptured.

shows merely one or two spaces lined by endothelium containing malignant cells. At one point an artery containing growth is present in the subcutaneous tissue, at another point are seen an artery and vein, both normal, accompanied by a permeated lymphatic.

Block 5.—Round-celled infiltration round the foci of growth, though still present, is becoming much less marked. No invaded blood-vessels are present either in this block or in the succeeding ones. The zone of permeation of the deep fascial plexus has now been reached and five foci of growth inclosed within endothelial walls are spaced out along the deep fascia. In places normal blood-vessels can be seen close to these spaces (Fig. 7). No large nodules are present in the section.

Block 6.—The appearances are similar to those in the preceding block. About 15 foci of growth, spaced out along the deep fascia, represent the permeated fascial plexus in cross-section (see Fig. 8). At two distinct points an artery and vein, both normal, are seen to be accompanied by two permeated lymphatics (Fig. 6).

Block 7 resembles Block 6. Here, again, normal blood-vessels are accompanied by permeated lymphatics. About six intravascular foci upon the fascia represent the permeated lymphatic plexus. Some of these lymphatics have ruptured and the growth within them is beginning to infiltrate the tissues. Microscopic invasion of the skin is still present.

Blocks 8 and 9.—These two blocks are characterised by the almost entire absence of round-celled infiltration round the minute foci of growth which are present. About eight of these foci, spaced out along the deep fascia, represent the permeated fascial plexus. No invaded blood-vessels are to be recognised, and at several points normal are to be seen lying close to permeated blood-vessels can be seen lying close to permeated lymphatics. A few scattered minute foci are present in the subcutaneous fat. The skin present in the subcutaneous fat. The skin present in the subcutaneous fat. The skin present in the subcutaneous fat.

ections until they may involve almost the whole of the face of the body. Usually, however, as in breast-cancer, patient dies before the distal portions of the limbs are acted. Such a mode of spread conclusively proves that embolism is not an invariable factor in the dissemination of skin nodules.

The following case⁵ may be quoted as a typical one. hers could be adduced if time allowed.

fr. D., et. 59, of fair complexion, had a mole situated midway between the umbilicus and the pubes. It commenced to enlarge in 7, while the surrounding skin assumed a brownish hue. Nine months afterwards the swelling was as large as a hen's egg, of a deep brown colour, firm and fleshy, broader at its apex than at its base and discharging an offensive ichorous fluid from its ulcerated surface. Some months after the appearance of this tumour several distinct nodules of similar structure sprang up around it. Owing to the discomfort and pain arising from the tumour it was excised, but recurred within six weeks. Soon the recurrent tumour was surrounded by bercles, some distinct, some confluent, of livid colour, at least 40 in number, forming a mass of disease extending from the spine of one arm to the other, and bearing some resemblance to a large bunch of red-coloured grapes. The inguinal glands were enlarged and the bercles continued to spread. Meantime the patient took exercise as attended to his business. Pains occasionally affected the tumour and adjacent parts, and an early and continued symptom was an excruciating pain just below the left kidney. The urine at times resembled porph. At length the constitutional symptoms became severe, with nausea, anorexia, restlessness, and depression. Dark blue dots arose in the vicinity of a mole on the sternum, others appeared in succession on the sides of the body and back, and very soon upon the forehead and scalp. Dyspnoea and dropsy came on, and his sufferings became severe until death relieved them. At the necropsy the sternum was thickly set with nodules, the lumbar and mesenteric glands were much enlarged. The spleen and bladder were the only abdominal organs free from disease. The chest was almost universally invaded. Similar diseased appearances were present on the skull cap and on the fascia covering the temporal muscles. The brain was healthy, and it is specially noted that with the exception of one speck in the leg the extremities were free from the disease.

This case, published in 1820, 14 years after Lasnece had described melanotic growths, was the first instance of malignant cutaneous melanoma described in England, and I may be permitted a word of pious reference to its chronicler, Dr. William Norris, a practitioner of Stourbridge. The cares of practice had not destroyed his enthusiasm for pathology, witness the following extract:—

When the abdomen, chest, and cranium were thrown open it was a most extraordinary phenomenon; thousands upon thousands of coal-black spots of circular shape and various sizes were to be seen closely besetting the shining mucous, serous, and fibrous membranes of most of the vital organs: I should think the most dazzling sight ever beheld by morbid anatomist. I shall never forget the pleasing thrill which came over me when I first beheld them. It would have puzzled the most powerful descriptive talent to have done full justice to such a novel and striking disease displayed so beautifully in endless profusion everywhere.

A country practitioner who loved his profession well enough to make a complete necropsy in private practice, and to ride 20 miles for the sight of a case of melanotic sarcoma, must have been in those days rather a rarity. Norris was, in fact, the intellectual grandson of John Hunter, as the pupil of Mr. Casner, one of Hunter's house surgeons. May we not trace in the pioneer work of Norris, in his power of accurate observation and record, and in his keen love of knowledge, the transmission through two generations, and by inference up to the present time, of Hunter's personal influence, and of the best qualities of his mind? The books and collections to which Hunter owes his nominal immortality are perhaps after all the lesser part of the legacy he has left.

As bearing upon the question of centrifugal spread it is of interest to note that when the primary tumour arises near the head the arms are attacked by subcutaneous nodules before the lower extremities; and, indeed, the lower limbs may remain entirely free from nodules until death occurs. Thus Anger⁶ records the following case:—

The patient was a woman of sixty, with a tumour as large as a nut upon the left cheek, which had been noticed for four months. Its growth was slow and painless. It was surrounded by four small jet-black tumours. The submaxillary glands were enlarged. Caustic was applied to the primary growth, but the satellite tumours were left alone and did not develop. The patient left the hospital in two months in a satisfactory state, but returned about a month later with multiple tumours of the form and colour of black currants upon the scalp, the neck, the arms, and the anterior and lateral parts of the chest and abdomen. The thighs, legs, and forearms were free from them. She died within a few days of readmission.

A COMPARISON BETWEEN THE MODE OF SPREAD OF CARCINOMA AND THAT OF MELANOTIC SARCOMA.

One of the aims of this research has been to test the conclusions on the spread of breast carcinoma at which I

⁵ William Norris, M.D.: Eight Cases of Melanosis, 1857; also Edinburgh Medical and Surgical Journal, October, 1820, p. 562.
⁶ Anger: Les Melanomes, Paris, 1856.

had previously arrived. For if it be granted that sarcoma can obtain access to and can exist within the lymphatic vessels its mode of spread within them must be to a certain extent determined by the same mechanical factors as in the case of carcinoma or of an artificial injection mass. My conclusions on the spread of breast-cancer were necessarily reached by microscopic methods only, but in melanotic sarcoma a direct appeal to the eye becomes possible; and Fig. 2 strengthens my former conclusions by indicating the identity of the mode of spread of melanotic sarcoma in the parietal tissues with the mode of spread which I inferred to take place in breast-cancer.

In the earlier stages the processes of dissemination are essentially identical in carcinoma and in melanotic sarcoma. Dissemination is initiated by the access of malignant cells to the fine lymphatics, followed by the centrifugal spread of permeation along the main lymphatic plexus into which the primary growth pours its lymph, and by secondary permeation of small tributaries of this plexus. Embolic invasion of the regional lymphatic glands occurs and around this fresh focus permeation recommences. Meanwhile, almost invariably in melanotic sarcoma and sometimes in carcinoma, invasion of the blood stream takes place, either by local infiltration of veins from comitant permeated lymphatics, or by malignant cells carried into the blood along the thoracic duct from invaded lymphatic glands. When this stage is reached dissemination in melanotic sarcoma and in carcinoma respectively develops along divergent lines. In carcinoma lymphatic permeation, aided by the escape of cancer cells into the serous cavities, usually remains to the end the main agent in producing secondary growths—a fact which appears to depend upon the almost invariable destruction of such epithelial cells as obtain access to the blood stream. The same mode of dissemination may sometimes occur in melanotic sarcoma, but as a rule the mesoblastic cells of melanotic sarcoma are able to thrive when lodged in a blood-vessel. Thus in the later stages of melanotic sarcoma the slow process of lymphatic permeation usually recedes into insignificance and the patient dies with almost universal deposits resulting from blood embolism—an event which only as a rare exception occurs in carcinoma.

The Lancelian Lectures

ON

THE INCREASE OF INSANITY.

Delivered before the Royal College of Physicians of London on March 14th, 19th, and 21st,

By G. H. SAVAGE, M.D. LOND.,
F.R.C.P. LOND.,

CONSULTING PHYSICIAN FOR, AND LATE LECTURER ON, MENTAL DISEASES, GUY'S HOSPITAL; CONSULTING PHYSICIAN TO THE IDIOT ASYLUM, EARLSWOOD.

LECTURE II.¹

Delivered on March 19th.

MR. PRESIDENT, FELLOWS, AND GENTLEMEN,—This lecture will be devoted to the causes of insanity. I shall only take a few of these such as will indicate sufficiently my views as to the probable increase among the insane. The three principal causes which I shall refer to are hereditary predisposition, alcoholic excess, and the influenzal poisoning.

The whole question of heredity is being studied with so much care that enormous numbers of facts have been added to our knowledge, but as yet no great and directing gold has been discovered, for though one has to accept it established that no mutilation or established acquisition transmitted to the offspring, yet I have to maintain many nervous peculiarities are passed on more or less from one generation to another. A considerable part of my lecture will be devoted to my views founded on my experience as to the amount and forms of neurosis which may be transmitted, and probably this is one of the most important that I have to consider. It is a very wide field that every case of insanity depends in some way on inheritance, and certainly the belief that insanity are equally dangerous, as far as

¹ Lecture I. was published in THE LANCET Oct.

the patient lives long enough) by a process of local inflammation essentially identical with the process of "perilymphatic fibrosis" which I have described in breast-cancer. Large secondary deposits, and in all probability even the primary growth itself (Fox), may sometimes be destroyed in a similar way. In this connexion my senior colleague, Mr. A. Pearce Gould,⁴ has lately recorded a very interesting case:—

H. S., *et. 38*, consulted Mr. Pearce Gould on June 23rd, 1933. A congenital mole on the front of his chest had begun to enlarge on June, 1902, and had been excised in October, 1932. A small healthy scar marked the site of the operation. It was soon followed by the appearance of tiny nodules in and under his skin. Mr. Gould found the nodules most numerous on the trunk, but they were scattered over almost the whole surface of the body, save that none were present on the lower limbs below the groins. On July 14th no new nodules had appeared and all the old ones were flatter and smaller. The enlarged glands were also smaller. On the 30th many of the nodules had disappeared altogether; others were present only as black stains, visible but not palpable. The glands had further diminished in size. On Oct. 1st he was found to have gained flesh and only two palpable nodules were present over the whole surface of the body. The glands in the groin were normal, those in the axillae but slightly enlarged. In February, 1934, two new nodules appeared near the right knee. In March the liver was enlarged and a fresh nodule appeared on the right side of the neck. The patient died in September, 1934, having been confined to his bed for only three or four days. While under Mr. Gould's care he took regularly a pill containing Venice turpentine and sulphur and amended an alcoholic habit which he had formed, but, as Mr. Gould remarks, the regressive changes which occurred were probably independent of these measures.

Mr. R. H. Jocelyn Swan has informed me of a somewhat similar case under his care in which macroscopic nodules of melanotic growth were observed to shrink and disappear.

CONCLUSIONS FROM EXAMINATION OF THE TISSUES IN THE INGUINAL REGION.

1. From the fairly regular distribution of skin nodules around the embolically invaded right inguinal glands it may be inferred that a process of local centrifugal spread, independent of the direction of the lymph current, took place around these glands as a focus.

Examination of a radial strip of the parietal tissues extending from these glands showed:—

2. That permeation of the lymphatics is the principal agent in this local centrifugal spread and that it occurs primarily and most extensively in the plane of the deep fascial lymphatic plexus.

3. Invasion of skin and muscle is due to upstream permeation of the lymphatics which carry lymph from these layers to the fascial lymphatic plexus.

4. Owing to the fact that arteries and veins usually run in close contiguity to lymphatic vessels lymphatic permeation is followed by infiltration of the walls of veins, and later of arteries, and by intrusion of the growth into the lumen of the blood-vessels. The importance of invasion of the veins with regard to pulmonary and systemic dissemination is obvious.

5. The order in time of these various events is deduced from the orderly sequence of processes seen as the strip of tissues is traced from its distal end towards the mass of glands which formed the local centre of infection.

6. Regressive changes, due to inflammation excited by the growth, may occur in melanotic sarcoma.

THE SHARE OF EMBOLISM IN PRODUCING THE METASTASES.

The direct evidence that the majority of the skin nodules present did not originate from emboli carried by the blood stream has already been adduced. It is interesting to note that nearly all the subcutaneous nodules present were situated on the same side as the primary growth. This distribution is inconsistent with the embolic origin of these particular secondary growths, and strongly suggest a process of local spread from point to point. On the other hand, it is probable that most of the visceral deposits, perhaps those in the breasts and a few of the subcutaneous nodules, took their origin in blood embolism. Such an embolic origin could be clearly traced in the kidneys, where the glomerular tufts were occupied in places by melanotic material, which at other points had burst into Bowman's capsule. Although "tissue-predisposition" is doubtless, as Mr. Stephen Paget showed, a factor in the survival of embolised fragments of

growth, it is difficult to explain on these lines the relative freedom from metastases of the subcutaneous tissues of the left side, as compared with those of the right side.

As soon as permeation in the lymphatics round the embolically invaded right femoral glands attained a radius of spread reaching to the level of the umbilicus—the dividing line between the territory of the inguinal and the axillary glands—embolic invasion of the axillary glands would occur. Local centrifugal spread around these glands, reaching a maximum in the rich lymphatic network of the breast, would account for the subcutaneous nodules present over the chest and for the mammary masses of growth.

DISEMINATION AROUND A PRIMARY MELANOTIC SARCOMA.

Since in this case the primary growth had been removed by operation, it was not possible to study centrifugal lymphatic spread around the primary focus, but only around a

FIG. 9.

× 160. Represents highly magnified, the lower circle B in Fig. 4 and illustrates the reparative processes which occur even in very malignant growths. A is a normal artery, G a mass of growth lying in a space without definite walls, which may be an artefact of the hardening process but in any case probably represents a ruptured lymphatic or vein. The growth G is surrounded by a very dense collection of inflammatory round cells R. In other parts of the section from which Fig. 9 is derived the later stages of perilymphatic fibrosis could be traced.

secondary focus—the embolically invaded inguinal glands of the right side.

No opportunity of investigating the spread of permeation round a primary focus of melanotic growth has fallen to me. Such opportunities must be extremely rare, for the examination of excised growths is unsatisfactory. But there is no lack of clinical evidence that permeation does occur round the primary growth as the initial step in the process of dissemination, a step soon followed by embolic invasion of the nearest glands along the trunk lymphatics. The appearance of subcutaneous nodules near the scar is one of the commonest sequels to the removal of a melanotic growth. As in the case of breast-cancer such nodules must be regarded as "efflorescences," not as a rule due to insufficient removal of skin but to incomplete removal of the permeated area of the fascial plexus. Generally subcutaneous nodules first appear close to the primary growth and spread from it in all

⁴ Pearce Gould: Archives of the Middlesex Hospital, vol. ix.

directions until they may involve almost the whole of the surface of the body. Usually, however, as in breast-cancer, the patient dies before the distal portions of the limbs are affected. Such a mode of spread conclusively proves that blood embolism is not an invariable factor in the dissemination of skin nodules.

The following case* may be quoted as a typical one. Others could be adduced if time allowed.

Mr. D., æt. 59, of fair complexion, had a mole situated midway between the umbilicus and the pubes. It commenced to enlarge in 1817, while the surrounding skin assumed a brownish hue. Nine months afterwards the swelling was as large as a hen's egg, of a deep brown colour, firm and fleshy, broader at its apex than at its base and exuding an offensive ichorous fluid from its ulcerated surface. Some few months after the appearance of this tumour several distinct brown nodules of similar structure sprang up around it. Owing to the discomfort and pain arising from the tumour it was excised, but recurred within six weeks. Soon the recurrent tumour was surrounded by tubercles, some distinct, some confluent, of livid colour, at least 40 in number, forming a mass of disease extending from the spine of one os ilium to the other, and bearing some resemblance to a large bunch of dark-coloured grapes. The inguinal glands were enlarged and the tubercles continued to spread. Meantime the patient took exercise and attended to his business. Pains occasionally affected the tumour and adjacent parts, and an early and continued symptom was an excruciating pain just below the left kidney. The urine at times resembled porter. At length the constitutional symptoms became severe, with nausea, anorexia, restlessness, and depression. Dark blue spots arose in the vicinity of a mole on the sternum, others appeared in succession on the sides of the body and back, and very soon upon the forehead and scalp. Dyspnoea and dropsy came on, and his sufferings became severe until death relieved them. At the necropsy the peritoneum was thickly set with nodules, the lumbar and mesenteric glands were much enlarged. The spleen and bladder were the only abdominal organs free from disease. The chest was almost universally invaded. Similar diseased appearances were present on the skull cap and on the fascia covering the temporal muscles. The brain was healthy, and it is especially noted that with the exception of one speck in the leg the extremities were free from the disease.

This case, published in 1820, 14 years after Laennec had described melanotic growths, was the first instance of malignant cutaneous melanoma described in England, and I may be permitted a word of pious reference to its chronicler, Dr. William Norris, a practitioner of Stourbridge. The cares of practice had not destroyed his enthusiasm for pathology, witness the following extract:—

When the abdomen, chest, and cranium were thrown open it was a most extraordinary phenomenon; thousands upon thousands of coal-black spots of circular shape and various sizes were to be seen closely dotting the shining mucous, serous, and fibrous membranes of most of the vital organs: I should think the most dazzling sight ever beheld by morbid anatomist. I shall never forget the pleasing thrill which came over me when I first beheld them. It would have puzzled the most powerful descriptive talent to have done full justice to such a novel and striking disease displayed so beautifully in endless profusion everywhere.

A country practitioner who loved his profession well enough to make a complete necropsy in private practice, and to ride 20 miles for the sight of a case of melanotic sarcoma, must have been in those days rather a rarity. Norris was, in fact, the intellectual grandson of John Hunter, as the pupil of Mr. Caser, one of Hunter's house surgeons. May we not trace in the pioneer work of Norris, in his power of accurate observation and record, and in his keen love of knowledge, the transmission through two generations, and by inference up to the present time, of Hunter's personal influence, and of the best qualities of his mind? The books and collections to which Hunter owes his nominal immortality are perhaps after all the lesser part of the legacy he has left.

As bearing upon the question of centrifugal spread it is of interest to note that when the primary tumour arises near the head the arms are attacked by subcutaneous nodules before the lower extremities; and, indeed, the lower limbs may remain entirely free from nodules until death occurs. Thus Anger* records the following case:—

The patient was a woman of sixty, with a tumour as large as a nut upon the left cheek, which had been noticed for four months. Its growth was slow and painless. It was surrounded by four small jet-black tumours. The submaxillary glands were enlarged. Caustic was applied to the primary growth, but the satellite tumours were left alone and did not develop. The patient left the hospital in two months in a satisfactory state, but returned about a month later with multiple tumours of the form and colour of black currants upon the scalp, the neck, the arms, and the anterior and lateral parts of the chest and abdomen. The thighs, legs, and forearms were free from them. She died within a few days of readmission.

A COMPARISON BETWEEN THE MODE OF SPREAD OF CARCINOMA AND THAT OF MELANOTIC SARCOMA.
One of the aims of this research has been to test the conclusions on the spread of breast carcinoma at which I

had previously arrived. For if it be granted that sarcoma can obtain access to and can exist within the lymphatic vessels its mode of spread within them must be to a certain extent determined by the same mechanical factors as in the case of carcinoma or of an artificial injection mass. My conclusions on the spread of breast-cancer were necessarily reached by microscopic methods only, but in melanotic sarcoma a direct appeal to the eye becomes possible; and Fig. 2 strengthens my former conclusions by indicating the identity of the mode of spread of melanotic sarcoma in the parietal tissues with the mode of spread which I inferred to take place in breast-cancer.

In the earlier stages the processes of dissemination are essentially identical in carcinoma and in melanotic sarcoma. Dissemination is initiated by the access of malignant cells to the fine lymphatics, followed by the centrifugal spread of permeation along the main lymphatic plexus into which the primary growth pours its lymph, and by secondary permeation of small tributaries of this plexus. Embolic invasion of the regional lymphatic glands occurs and around this fresh focus permeation recommences. Meanwhile, almost invariably in melanotic sarcoma and sometimes in carcinoma, invasion of the blood stream takes place, either by local infiltration of veins from comitant permeated lymphatics, or by malignant cells carried into the blood along the thoracic duct from invaded lymphatic glands. When this stage is reached dissemination in melanotic sarcoma and in carcinoma respectively develops along divergent lines. In carcinoma lymphatic permeation, aided by the escape of cancer cells into the serous cavities, usually remains to the end the main agent in producing secondary growths—a fact which appears to depend upon the almost invariable destruction of such epithelial cells as obtain access to the blood stream. The same mode of dissemination may sometimes occur in melanotic sarcoma, but as a rule the mesoblastic cells of melanotic sarcoma are able to thrive when lodged in a blood-vessel. Thus in the later stages of melanotic sarcoma the slow process of lymphatic permeation usually recedes into insignificance and the patient dies with almost universal deposits resulting from blood embolism—an event which only as a rare exception occurs in carcinoma.

the patient lives long enough) by a process of local inflammation essentially identical with the process of "perilymphatic fibrosis" which I have described in breast-cancer. Large secondary deposits, and in all probability even the primary growth itself (Fox), may sometimes be destroyed in a similar way. In this connexion my senior colleague, Mr. A. Pearce Gould,⁴ has lately recorded a very interesting case:—

II. S., at 33, consulted Mr. Pearce Gould on June 23rd, 1903. A congenital mole on the front of his chest had begun to enlarge on June, 1902, and had been excised in October, 1902. A small healthy scar marked the site of the operation. It was soon followed by the appearance of tiny nodules in and under his skin. Mr. Gould found the nodules most numerous on the trunk, but they were scattered over almost the whole surface of the body, save that none were present on the lower limbs below the groins. On July 14th no new nodules had appeared and all the old ones were flatter and smaller. The enlarged glands were also smaller. On the 30th many of the nodules had disappeared altogether; others were present only as black stains, visible but not palpable. The glands had further diminished in size. On Oct. 1st he was found to have gained flesh and only two palpable nodules were present over the whole surface of the body. The glands in the groin were normal, those in the axillæ but slightly enlarged. In February, 1904, two new nodules appeared near the right knee. In March the liver was enlarged and a fresh nodule appeared on the right side of the neck. The patient died in September, 1904, having been confined to his bed for only three or four days. While under Mr. Gould's care he took regularly a pill containing Venice turpentine and sulphur and amended an alcoholic habit which he had formed, but, as Mr. Gould remarks, the regressive changes which occurred were probably independent of these measures.

Mr. R. H. Jocelyn Swan has informed me of a somewhat similar case under his care in which macroscopic nodules of melanotic growth were observed to shrink and disappear.

CONCLUSIONS FROM EXAMINATION OF THE TISSUES IN THE INGUINAL REGION.

1. From the fairly regular distribution of skin nodules around the embolically invaded right inguinal glands it may be inferred that a process of local centrifugal spread, independent of the direction of the lymph current, took place around these glands as a focus.

Examination of a radial strip of the parietal tissues extending from these glands showed:—

2. That permeation of the lymphatics is the principal agent in this local centrifugal spread and that it occurs primarily and most extensively in the plane of the deep fascial lymphatic plexus.

3. Invasion of skin and muscle is due to upstream permeation of the lymphatics which carry lymph from these layers to the fascial lymphatic plexus.

4. Owing to the fact that arteries and veins usually run in close contiguity to lymphatic vessels lymphatic permeation is followed by infiltration of the walls of veins, and later of arteries, and by intrusion of the growth into the lumen of the blood-vessels. The importance of invasion of the veins with regard to pulmonary and systemic dissemination is obvious.

5. The order in time of these various events is deduced from the orderly sequence of processes seen as the strip of tissues is traced from its distal end towards the mass of glands which formed the local centre of infection.

6. Regressive changes, due to inflammation excited by the growth, may occur in melanotic sarcoma.

THE SHARE OF EMBOLISM IN PRODUCING THE METASTASES.

The direct evidence that the majority of the skin nodules present did not originate from emboli carried by the blood stream has already been adduced. It is interesting to note that nearly all the subcutaneous nodules present were situated on the same side as the primary growth. This distribution is inconsistent with the embolic origin of these particular secondary growths, and strongly suggest a process of local spread from point to point. On the other hand, it is probable that most of the visceral deposits, perhaps those in the breasts and a few of the subcutaneous nodules, took their origin in blood embolism. Such an embollic origin could be clearly traced in the kidneys, where the glomerular tufts were occupied in places by melanotic material, which at other points had burst into Bowman's capsule. Although "tissue-predisposition" is doubtless, as Mr. Stephen Paget showed, a factor in the survival of embolised fragments of

growth, it is difficult to explain on these lines the relative freedom from metastases of the subcutaneous tissues of the left side, as compared with those of the right side.

As soon as permeation in the lymphatics round the embolically invaded right femoral glands attained a radius of spread reaching to the level of the umbilicus—the dividing line between the territory of the inguinal and the axillary glands—embolic invasion of the axillary glands would occur. Local centrifugal spread around these glands, reaching a maximum in the rich lymphatic network of the breast, would account for the subcutaneous nodules present over the chest and for the mammary masses of growth.

DISSEMINATION AROUND A PRIMARY MELANOTIC SARCOMA.

Since in this case the primary growth had been removed by operation, it was not possible to study centrifugal lymphatic spread around the primary focus, but only around a

FIG. 9.

× 160. Represents highly magnified, the lower circle B in Fig. 4 and illustrates the reparative processes which occur even in very malignant growths. A is a normal artery, G a growth of granular cells in a space without definite walls, which may be an artefact of the hardening process but in any case probably represents a ruptured lymphatic or vein. The growth G is surrounded by a very dense collection of inflammatory round cells R. secondary focus—the embolically invaded inguinal glands on the right side.

No opportunity of investigating the spread of permeatic round a *primary* focus of melanotic growth has fallen to me. Such opportunities must be extremely rare, for the examination of excised growths is unsatisfactory. But there is a lack of clinical evidence that permeation does occur round the primary growth as the initial step in the process of dissemination, a step soon followed by embolic invasion of the nearest glands along the trunk lymphatics. The appearance of subcutaneous nodules near the scar is one of the commonest sequels to the removal of a melanotic growth. A in the case of breast-cancer such nodules must be regarded as "efflorescences," not as a rule due to insufficient removal of skin but to incomplete removal of the permeated area or the fascial plexus. Generally subcutaneous nodules first appear close to the primary growth and spread from it in all

It will be my duty later to point out special forms of mental disorder which, in my experience, have been clearly related to insane inheritance. It may be said in passing that it is fully recognised that brain tumours, general paralysis of the insane, and many cases of senile dementia have little to do with neurotic inheritance; while, on the other hand, it is manifest that certain forms of delusional insanity, moral insanity, and the insanity of obsessions almost invariably have inheritance of insanity, or allied states, as a partial cause.

We have always to bear in mind, when we meet with insanity in children, that besides inheritance there is association. It is quite certain that the association of an insane parent with children may be extremely dangerous. I have seen very clear and distinct examples of the *folie à deux*, such as the following. A mother is left a widow with two children and a very small amount of money to live upon. She has to change her residence and lives in a poor and meagre way. Avoiding the expense of entertaining friends she and her children live absolutely alone. She gets morbidly suspicious about them and about everybody in the neighbourhood, begins to suspect people of talking about her, of interfering with her, and, perhaps, tampering with her food. This is slowly borne in upon the young children, who in due course develop similar delusions. That, of course, is an extreme case, but it bears out what one wishes to impress upon you, that the association of the insane parent with the child may have a dangerous effect upon the mental stability of the child.

Again, it is not an uncommon experience for me to be consulted about the daughter of some elderly widow who has died after a prolonged mental illness. The daughter has devoted herself body and soul to this mother who has been a chronic or paralytic dement. In due course, after the death of the mother, the daughter begins to wonder whether her mother's symptoms are not reappearing in herself and it has been not an uncommon experience for me to see such a daughter mimicking to a great extent the symptoms of her mother. Expectancy and association have a great deal to do with heredity.

It has been thought that there is a great danger of transmission of the suicidal tendency and I would put it in this way: that I have histories of families many members of which have committed suicide, and in many cases the suicides have occurred in different parts of the world and under different conditions, and apparently without any knowledge of the occurrence of suicide in any other members of the family. This, of course, may or may not be quite accurate. At all events, I have known families in which suicide has been common. Such families undoubtedly belong to the unstable, to the neurotic—that is, to those who are unduly sensitive and unduly emotional. I say that probably there is a tendency to transmit not necessarily melancholia, but emotional states which readily lead to melancholia; and so people who are unusually sensitive and unusually emotional react too readily to painful surroundings and the tendency is to suicide. That definite concrete ideas or delusions should reappear apart from collusion seems to me at least improbable, yet I have had several instances like the following. I was consulted about a girl, aged 20 years, who, being sleepless and depressed, accused herself of the unpardonable sin. After some weeks she improved and finally recovered. Then her father, a bright and prominent business man, called on me and said that for years he had been convinced that he was "the man of sin," that he had committed "the unpardonable sin," and that there was no hope for him. He, being convinced of his doom, had borne it without a word to his family and he was horrified to find its reappearance in his daughter. It is difficult to explain this case, though I should say that a family in which unpardonable sin is talked about and thought about is sure to be impregnated with depressing religious views, which tend to a scriptural interpretation. And thus I would explain the occurrence of a similar idea in a child and in a parent.

Undoubtedly, although one does not get the fully developed delusion often in parent and child, I have seen such cases as the following: A father consulted me about his daughter, saying that she had morbid dreads about trains, about heights, and about being in public places. He said it was very alarming to him, because he himself had similar feelings all his life. That a nervous unstable person should have these similar dreads is common. I am constantly in the habit of seeing children who certainly, by the time they are 12 or 13

years of age, have dreads of heights, dreads of trains, and the like. They belong almost invariably to neurotic and possibly insane stock. That father and daughter should have such ideas is merely saying that under similar conditions similar feelings are similarly interpreted. That bears upon another point which I think is of value and importance. It is, that though these single isolated delusions or ideas may occur in a large number of neurotic people, they do not as a rule tend to further mental disorder; that they resemble in fact the stammer or trick in speech, or facial movements which are so common among the neurotic. There may be a single dominant idea, which recurs but does not lead to further disorder. The person with a stammer may go on all his life stammering, and this may be corrected to a certain extent. And in the same way there are many persons who have mental stammers, if I may use the term, and yet who do not become more insane. In such cases I have been often asked as to the danger of marriage. And I admit that I almost invariably say, "Well, it is quite possible that you may have children who will experience similar feelings to those from which you suffer. If you find them so intolerable to yourself pray warn your children as to the danger of their possessing them. But otherwise I do not think you need be afraid; that is, you need not be afraid if the child be a daughter that she will break down with puerperal insanity, or if he be a son that he is likely to develop general paralysis."

Allied to what I have just said, I would wish to make clear that people belonging to a neurotic stock, people who are likely to transmit the neurotic tendency to their children if they become insane, have certain definite peculiarities. I have observed that it is possible for many of them to have obsessions or monomanias, if one may still use the term; moral and sensory, rather than intellectual defects. But besides this there is a great tendency to develop hallucinations of the senses. I have sometimes felt inclined to say the neurotic are more likely to go out of their senses than out of their minds. Delusional insanity associated with hallucinations of hearing, sight and of the other special senses is common among neurotics. Then it is noteworthy that the person who is of very insane stock is much more likely to break down at certain periods of life. And this, again, is an important point when we are considering the question of the increase in the numbers of the insane. It is pretty certain that a large number of the patients who are now described as suffering from dementia præcox belong to neurotic stock. It is thought that those coming of neurotic stock are more liable to break down under what may be called physiological stress; that with adolescence, with child-bearing, with change of life they are more likely to break down. Next, those belonging to strongly nervous stock are likely to recover at least once, except those cases of quite early developing or developmental insanity. I have long been in the habit of saying that if a person had to become insane it was very much better for his prospects of, at all events, recovering that he should have had an insane parent. The tolerance of recurring attacks of very violent insanity in neurotic persons is extraordinary. I have known members of insane families who have had recurring attacks during 30 and 40 years, attacks of most violent mania or most profound melancholia, which have passed off, leaving no evidence of the tremendous mental storms that have raged. Readily upset as these neurotics are they seem capable of being reset to an unusual degree.

As to the question of inheritance in relationship to the various forms of insanity, I have already pointed out that the types of delusional insanity are specially associated with a neurotic inheritance. I have also said that general paralysis of the insane, as a rule, has but a distant relationship to inheritance. I am inclined to think that with melancholia there is a greater tendency to transmission than with mania or with some other forms of insanity. In melancholia one has such a large amount of disorder, evidenced by changes in the body as well as by changes in the mind, that one is not altogether surprised to find that a tendency to melancholia runs not uncommonly in families. Again, this is of importance in connexion with the question of increase among the insane. A large number of people who now live to 80 years of age, or even more, in asylums are suffering from melancholia. The weight of years is represented by melancholia in some families, and I have known some very distinguished families the members of which when they approach fourscore years exhibit signs of melancholia and end in mental gloom.

is concerned, is very widely spread. If I have succeeded in making anything clear in my first lecture I hope it is that there is no definite form of insanity which is likely to be transmitted. The importance of considering in detail the relationship of inheritance to mental disorders is not only medical but social. It is a question that medical men, especially family medical men, have frequently before them—the danger of marrying into families in which cases of insanity have occurred. In some cases, undoubtedly, alliances of that kind are to be hindered and, if possible, stopped altogether. On the other hand, there are many cases in which insanity of the parent is not more likely to be transmitted in any shape or form to the descendants than an accidental injury or mutilation. In passing, one would say that the same holds good in relationship to consanguineous marriages. It used to be believed that a large percentage of deaf mutes in asylums, and of the imbeciles and idiots who are met with, are the result of consanguineous unions. It is pretty conclusively proved that consanguinity itself is of little or no importance. In fact, if the two blood relations happen to belong to absolutely healthy stock the progeny themselves will have an excellent chance of being healthy. If, on the other hand, there is any tendency to neurosis in the stock, or if there is a tendency to neurosis on the one hand, and to degenerative disorders, such as phthisis, on the other, then undoubtedly the union of blood relations is specially dangerous. In some cases one has seen unions that one would not have advised still turn out quite satisfactory. It therefore is my opinion that although it is undesirable that neurotics should marry one another, yet the marriage of a neurotic with a perfectly sound and healthy individual is much more likely to eradicate the neuroses in the offspring than to accentuate them. It has been thought that some of the increase among the insane depended upon the fact that a large number of patients were now discharged convalescent from asylums before they were really well and that during this period of convalescence they might become pregnant or might beget children who would certainly be predisposed to nervous disorders. The statistics of asylums, especially those given recently from the Irish asylums, do not in any way substantiate this belief. There undoubtedly are cases, and such have come before my immediate notice, in which a patient recently recovered from insanity has become the parent of a child who has been unduly unstable. No statistics, however, are available to show that any increase of insanity depends upon any such cause. I am in the habit of comparing neuroses to the mycelium of a fungus; just as the plant grows unseen beneath the surface and is only recognised by the development of the mushroom or the toadstool, so the inherited neurosis may be hidden and only appear under special conditions. I believe there is a neurotic type, to which I shall have later to refer, which may produce a brilliant result, on the one hand, or, given other conditions, may lead to a disastrous or dangerous product, either criminal or lunatic. It has to be recognised that though insanity itself in a definite form is not transmitted there is a tendency to develop various forms of a neurosis which are transmitted, and I am inclined to think that the increase of insanity at the present time depends to a certain extent upon such transmission.

I would definitely say that mental disorder reaching the line of insanity is to be compared with highly specialised mental capacity—with genius, if you like—and that this is not at all likely to be passed on. The poet, or the distinguished statesman, rarely has similarly gifted children. The lunatic may have defective children, and if the mental disorder is of a grave type, and if the children have been born after there has been definite mental breakdown, idiocy rather than lunacy is to be expected. I feel some hesitancy in dogmatizing on the relationship between genius and insanity; the subject has been so frequently handled that I fear little that I could say so frequently to your knowledge. But I am more and more struck by the fact that any individual who has become markedly conspicuous along any very definite or specialised line has a conspicuous tendency to transmit not that special ability or distinct tendency to transmit but that special ability or capacity but an instability which may lead to mental incapacity of one type or another. I would go so far as to say that special capacity or genius, whether it be on the mental or even muscular side, is associated with danger. I may say that in my experience I have seen the neurotic disposition show itself in the descendants of athletes, inventors, poets, statesmen, and the like. The tendency of

gifted parents either to have no children at all or to have neurotic children is established. It is not unnatural, and certainly follows the lines of Darwin's observations, that no great special or individual capacity is transmitted. The variation of species, if it has originated by slow additions or slow modifications of existing bodies, must have been associated with transmission of extraordinarily minute changes, and one is more and more convinced that specific changes have not been by leaps and bounds. It is probable that any qualities that are transmitted from parent to child will be small; you do not get a poetic child of a poetic father, but you would get a child with sensory or intellectual instability, a tendency perhaps to emotional display. In fact, tricks of body (extra fingers) and tricks of mind are much more likely to reappear in the children than are the great and marked characteristics. I think most of us recognise that very slight habits are conspicuous by their reappearance in a second or third generation. For instance, I personally have been very much impressed by the transmission of special forms of handwriting. Thus a mother writing a bad hand and a father writing a good one, it has been my frequent experience to find the sons following the type of writing of the mother, the daughters that of the father. And in some such cases the characteristic writing has been very marked, although the children have been brought up away from home almost entirely. In one very interesting case a man, the son of an insane mother, himself sane, married and had a son who was markedly neurotic. He lost his wife, married again, and had a daughter who exhibited similar symptoms of nervous instability to her half-brother. The mothers were both apparently healthy.

Now as to some of my experience in relationship to inheritance and the transmission of neuroses. I have had opportunities of seeing children of an insane mother, a mother who, even during her insanity, lived with her husband and bore children. I have known those children grow up, at all events, into adolescence without any sign of mental disorder. They have been somewhat unstable, that is, emotional, given, perhaps, to infantile rages, predisposed to variations in temperature with but slight cause, with a tendency to dreaminess, and occasionally with certain other minor nervous symptoms. I have, on the other hand, seen children who have been born of a mother who has suffered from puerperal insanity, who, therefore, has not developed from insanity until after the birth of the child, but who yet—the insanity until after the birth of the child, but who yet—if I may refer once more to my simile of the mycelium of the fungus—was practically insane, if not actually insane, during the pregnancy. I have known such children come into the world not insane, but with marked tendency to convulsive seizures, leading ultimately to epilepsy and to moral defects of one kind or another. These individuals are very often good examples of the anti-social tendency to the anti-social side of mental disorder. The children of an insane parent may tend rather, as I say, to emotional instability and to moral defect than to actual intellectual want.

Undoubtedly a certain number of idiots are the result of insane parents, but my experience is that a very large percentage of idiots have no distinct insanity in their ancestors. Just as in the common chemical experiment it used to be shown that two colourless solutions when mixed may produce a black solution or precipitate, so it has been my constant experience to find that when a family consists of several idiotic children the parents have not, either of them, been insane, but have, on the other hand, been highly neurotic, or have been peculiar in one way or another, so that without ever having been considered insane, they have been looked upon as unstable and the result has been weak-minded progeny. Doubtless, sooner or later, one may be able to recognise what the types are who, when united, produce such disastrous results. I should give as my experience, too, that a child begotten of a degenerating parent—one, say, broken down from alcoholic excess, from general paralysis of the insane, or from some senile disorder—would very likely be imbecile or idiotic. I have a certain number of special instances in which I have known the result of impregnation by a general paralytic father to have been an idiotic child. It is difficult, however, from a few individual cases, to generalise. Though I do not expect the insane parent to have an insane offspring, yet, as many insane people belong to a specially unstable class, I find the offspring of the insane or highly neurotic to develop certain special forms of nervous disorder.

It will be my duty later to point out special forms of mental disorder which, in my experience, have been clearly related to insane inheritance. It may be said in passing that it is fully recognised that brain tumours, general paralysis of the insane, and many cases of senile dementia have little to do with neurotic inheritance; while, on the other hand, it is manifest that certain forms of delusional insanity, moral insanity, and the insanity of obsessions almost invariably have inheritance of insanity, or allied states, as a partial cause.

We have always to bear in mind, when we meet, with insanity in children, that besides inheritance there is association. It is quite certain that the association of an insane parent with children may be extremely dangerous. I have seen very clear and distinct examples of the *folie à deux*, such as the following. A mother is left a widow with two children and a very small amount of money to live upon. She has to change her residence and lives in a poor and meagre way. Avoiding the expense of entertaining friends she and her children live absolutely alone. She gets morbidly suspicious about them and about everybody in the neighbourhood, begins to suspect people of talking about her, of interfering with her, and, perhaps, tampering with her food. This is slowly borne in upon the young children, who in due course develop similar delusions. That, of course, is an extreme case, but it bears out what one wishes to impress upon you, that the association of the insane parent with the child may have a dangerous effect upon the mental stability of the child.

Again, it is not an uncommon experience for me to be consulted about the daughter of some elderly widow who has died after a prolonged mental illness. The daughter has devoted herself body and soul to this mother who has been a chronic or paralytic dement. In due course, after the death of the mother, the daughter begins to wonder whether her mother's symptoms are not reappearing in herself and it has been not an uncommon experience for me to see such a daughter mimicking to a great extent the symptoms of her mother. Expectancy and association have a great deal to do with heredity.

It has been thought that there is a great danger of transmission of the suicidal tendency and I would put it in this way: that I have histories of families many members of which have committed suicide, and in many cases the suicides have occurred in different parts of the world and under different conditions, and apparently without any knowledge of the occurrence of suicide in any other members of the family. This, of course, may or may not be quite accurate. At all events, I have known families in which suicide has been common. Such families undoubtedly belong to the unstable, to the neurotic—that is, to those who are unduly sensitive and unduly emotional. I say that probably there is a tendency to transmit not necessarily melancholia, but emotional states which readily lead to melancholia; and so people who are unusually sensitive and unusually emotional react too readily to painful surroundings and the tendency is to suicide. That definite concrete ideas or delusions should reappear apart from collusion seems to me at least improbable, yet I have had several instances like the following. I was consulted about a girl, aged 20 years, who, being sleepless and depressed, accused herself of the unpardonable sin. After some weeks she improved and finally recovered. Then her father, a bright and prominent business man, called on me and said that for years he had been convinced that he was "the man of sin," that he had committed "the unpardonable sin," and that there was no hope for him. He, being convinced of his doom, had borne it without a word to his family and he was horrified to find its reappearance in his daughter. It is difficult to explain this case, though I should say that a family in which unpardonable sin is talked about and thought about is sure to be impregnated with depressing religious views, which tend to a scriptural interpretation. And thus I would explain the occurrence of a similar idea in a child and in a parent.

Undoubtedly, although one does not get the fully developed delusion often in parent and child, I have seen such cases as the following: A father consulted me about his daughter, saying that she had morbid dreads about trains, about heights, and about being in public places. He said it was very alarming to him, because he himself had similar feelings all his life. That a nervous unstable person should have these similar dreads is common. I am constantly in the habit of seeing children who certainly, by the time they are 12 or 13

years of age, have dreads of heights, dreads of trains, and the like. They belong almost invariably to neurotic and possibly insane stock. That father and daughter should have such ideas is merely saying that under similar conditions similar feelings are similarly interpreted. That bears upon another point which I think is of value and importance. It is, that though these single isolated delusions or ideas may occur in a large number of neurotic people, they do not as a rule tend to further mental disorder; that they resemble in fact the stammer or trick in speech, or facial movements which are so common among the neurotic. There may be a single dominant idea, which recurs but does not lead to further disorder. The person with a stammer may go on all his life stammering, and this may be corrected to a certain extent. And in the same way there are many persons who have mental stammers, if I may use the term, and yet who do not become more insane. In such cases I have been often asked as to the danger of marriage. And I admit that I almost invariably say, "Well, it is quite possible that you may have children who will experience similar feelings to those from which you suffer. If you find them so intolerable to yourself pray warn your children as to the danger of their possessing them. But otherwise I do not think you need be afraid; that is, you need not be afraid if the child be a daughter that she will break down with puerperal insanity, or if he be a son that he is likely to develop general paralysis."

Allied to what I have just said, I would wish to make clear that people belonging to a neurotic stock, people who are likely to transmit the neurotic tendency to their children if they become insane, have certain definite peculiarities. I have observed that it is possible for many of them to have obsessions or monomanias, if one may still use the term; moral and sensory, rather than intellectual defects. But besides this there is a great tendency to develop hallucinations of the senses. I have sometimes felt inclined to say the neurotic are more likely to go out of their senses than out of their minds. Delusional insanity associated with hallucinations of hearing, sight and of the other special senses is common among neurotics. Then it is noteworthy that the person who is of very insane stock is much more likely to break down at certain periods of life. And this, again, is an important point when we are considering the question of the increase in the numbers of the insane. It is pretty certain that a large number of the patients who are now described as suffering from dementia praecox belong to neurotic stock. It is thought that those coming of neurotic stock are more liable to break down under what may be called physiological stress; that with adolescence, with child-bearing, with change of life they are more likely to break down. Next, those belonging to strongly nervous stock are likely to recover at least once, except those cases of quite early developing or developmental insanity. I have long been in the habit of saying that if a person had to become insane it was very much better for his prospects of, at all events, recovering that he should have had an insane parent. The tolerance of recurring attacks of very violent insanity in neurotic persons is extraordinary. I have known members of insane families who have had recurring attacks during 30 and 40 years, attacks of most violent mania or most profound melancholia, which have passed off, leaving no evidence of the tremendous mental storms that have raged. Readily upset as these neurotics are they seem capable of being reset to an unusual degree.

As to the question of inheritance in relationship to the various forms of insanity, I have already pointed out that the types of delusional insanity are specially associated with a neurotic inheritance. I have also said that general paralysis of the insane, as a rule, has but a distant relationship to inheritance. I am inclined to think that with melancholia there is a greater tendency to transmission than with mania or with some other forms of insanity. In melancholia one has such a large amount of disorder, evidenced by changes in the body as well as by changes in the mind, that one is not altogether surprised to find that a tendency to melancholia runs not uncommonly in families. Again, this is of importance in connexion with the question of increase among the insane. A large number of people who now live to 80 years of age, or even more, in asylums are suffering from melancholia. The weight of years is represented by melancholia in some families, and I have known some very distinguished families the members of which when they approach fourscore years exhibit signs of melancholia and end in mental gloom.

I here add some extracts from the Irish Commissioners' reports, giving the opinions of some of the asylum physicians. Taking the percentages *seriatim* it will be seen that during the decade the proportion of cases in which heredity was a factor in the causation shows a small increase.

Page 7.—So far as the figures at our disposal go, there is no ground for the idea that asylums are breeding places of insanity, turning out every year thousands of patients technically "cured," but with the evil in the blood to beget an infected progeny. No facts have come to my knowledge to warrant such a theory. I find no cases of patients descended from former inmates of the asylum who have been discharged as recovered. It cannot be denied that discharged patients may marry and propagate the disease, but a kind of corrective is supplied in public sentiment which condemns such marriages. The greatest misconceptions prevail as to heredity in its causative relation to insanity. The truth is, mental, like most bodily diseases, are not in themselves directly transmissible. We inherit not insanity but an ill-adjusted nervous system, which may easily collapse beneath an unaccustomed strain. That heredity marks out the lines along which the chartered curses of humanity find easy progress we must believe. (Graham.)

Page 13.—As a result of my observations here and elsewhere I am convinced that heredity is largely accountable for the prevailing insanity. I have frequently had insane parents and their children receive treatment at the same time, and sometimes as many as three or four members of the same family. There is no doubt that in many instances the patients are descended from former inmates of the asylum who had been discharged recovered or improved. (Hatchell.)

Page 16.—CAUSES OF INSANITY.—The most prominent of these amongst those admitted has to be recorded as usual under the head of hereditary; 49 out of a total of 113 were assigned this as a cause. This probably does not represent all who might truly be added here—for various reasons we are not always able to arrive at the truth; nine were said to be caused by congenital defects. (Harvey.)

Page 19.—Hereditary exercise its influence chiefly at adolescence, and when the exciting cause which has brought on the attack has been removed the patient usually recovers, often marries, and has a family more or less liable to insanity, epilepsy, or some neurotic disease. (Yoods.)

Page 21.—In connexion with the question of heredity, which undoubtedly is one of the most important considerations in connexion with the problem of insanity, it is a consolation to know, as the outcome of modern research, that the old pessimistic doctrine of a hopelessly handicapped posterity springing from insane progenitors is no longer absolute. (Nolan.)

Page 13.—We therefore find that a preponderance of the cases breaking out without well-marked exogenous cause in the time of late boyhood or early manhood are cases in which there is some strong hereditary tendency, or cases that are stigmatised from the first either by definite physical defects and malformations or by distinct nervous instability. These are, in other words, cases of constitutional or idiopathic predilection. (Conolly Norman.)

primordial predisposition. (Conolly Norman.)

Page 51.—With regard to the great question of heredity, it is easy to attribute an undue importance to this factor. I do not go so far as to deny, as some have done in modern times, that it is a factor at all, but I must point out that it is extremely indefinite. With a disease so common as insanity, if those who are hereditarily tainted constituted a distinct class, that fact would soon be patent to the world. But they do not, and this suggests that the incidence of insanity is scattered pretty generally through the population. It is true that the more carefully one examines into the family history of sufferers from mental unsoundness the more sure one is to come across cases of mental and other nervous diseases. But on the other hand, when one has an opportunity of examining a family history, starting from a person who is not of unsound mind, one comes across mental and nervous disease quite in a similar way. Indeed, as far as I am able to judge, facts bear out speculation, and everyone has insane relations, nearer, as the case may be, or more remote. Heredity would be much more often assigned to insanity than it is were it not for the reticence and the ignorance of relatives, but this would make little difference in the nature of the problem. Of course, no clinical observer of experience has failed to recognise families in which the liability to insanity is strong, and even tends to increase, till it terminates in the destruction of the stock. But in the majority of cases heredity can hardly be regarded as more than a disposition, common to our race, a little stronger in one than in another, and usually requiring some second or contributing agency to make it operative.

Table IV., under the heading of heredity,

The statistics given in Table IV, under the heading of heredity, cannot be quite accurate, as may be given greater weight to heredity said above, but the tendency has been to give greater weight to heredity as the years went on, and no increase under this head has been noticeable. Now with regard to the specific question as to whether an appreciable increase in the number of the insane has been brought about through the discharge of recovered patients who have then propagated the statistics of this asylum nor the facts of my own experience give any support to this notion. (Conolly Norman.)

Melancholic states are much more likely to occur, I think, in families than are maniacal conditions; that of all forms of hereditary insanity, those associated with hallucinations of the senses and with definite obsessions and marked delusions are common; that with a strong inheritance there is a tendency to moral defect as well as to imbecility and idiosyncrasy; that consanguinity alone is not to be looked upon as very dangerous. I take it for granted that there is no such thing as inheritance of any function as such, but only the transmission of the physical capacity or predisposition to react in certain definite ways under certain definite stimulation. Thus, the power to learn to speak exists, but not the special tendency to speak in one language. Again, manual aptitudes may be present, but there is no special transmission of power to perform definite acts in definite

ways. The power of rapidly varying in relationship to rapidly changing surrounding is represented by still more and more mobile organic compounds. The possession of such mobile combinations tends to instability; and, after all, we have to consider neurosis as nothing but a special form of instability. Such instability may be represented by brilliant genius or feeble inconsequence. As already pointed out, various neuroses are allied and may in some cases be interchangeable. Neurotic instability and tendency to insanity may depend on causes of physical weakness in a parent, yet unstable parents may have normal children. Atavism is not so marked in insanity as in some forms of physical peculiarity. It is not true that all forms of insanity are easily transmitted to the offspring. Healthy mating, too, may get rid of the tendency, or may result in but a slight tendency to tricks, habits, or manners representing the neurosis in the parent. Strong neurotic inheritance will often show itself in special forms of nervous disorder in childhood and adolescence, and, again, in anti-social or criminal tendencies.

THE AREA OF "ACUTE ABDOMINAL
CONFLUX" AND THE "INCISION
OF INCIDENCE."

BY CHARLES P. CHILDE, B.A., F.R.O.S. ENG.,
SURGEON TO THE ROYAL PORTSMOUTH HOSPITAL.

IN the acute abdomen, notwithstanding an exhaustive inquiry into the previous history and present illness, a thorough abdominal, rectal (and in the case of a woman vaginal) examination, an inspection of the vomit and excreta if any, a close scrutiny of the various hernial rings, and a second examination after the patient has been brought under the influence of the anæsthetic, yet in a certain proportion of cases the surgeon will be in doubt as to the nature of the illness with which he has to deal. This is owing to the fact that the general symptoms—pain, collapse, vomiting, followed by distension—are common to most, if not all, the conditions producing the acute abdomen, while the distinguishing features of any particular affection may be absent. A perforated duodenal ulcer, for instance, may be indistinguishable from an acute perforative or gangrenous appendicitis; the latter may simulate acute intestinal obstruction from various causes, a gangrenous pancreatitis may imitate an acute perforation of the digestive tract, and so on. In such cases the surgeon only knows that an acute abdominal catastrophe has occurred and he feels certain that, humanly speaking, the only chance lies in immediate operation. Many of these patients have been ill two or three days or longer, their abdomens are distended, rendering examination negative, and their general condition is bad. In these unfavourable circumstances the surgeon is conscious that if he is fortunate enough to hit on the source of mischief at once he is fortunate enough to hit on the source of mischief at once and succeeds in remedying it without undue delay, the patient's life may be saved. If, on the other hand, he is not so fortunate and a prolonged search, followed possibly by a second incision or evisceration, is needed, though the operation may be concluded successfully, the ordeal will have been beyond the patient's power to survive. We then frequently hear that, "though the operation was perfectly successful, the patient died the next day"—a somewhat paradoxical and poor consolation. If as a result of his examination the surgeon arrives at a probable diagnosis he will usually make his incision over the suspected organ—and rightly so, too, even though he should turn out to be wrong. But should his examination leave him completely in the dark as to its nature, where is he to make it? It is generally advised that the exploratory incision be made in the middle line below the umbilicus and the whole or part of the hand be introduced to ascertain the source of the trouble. The intention of the present paper is to question the soundness of this advice and to advocate the right semilunar line as the position of election. We are dealing with a question of probabilities. The objective in view is to hit on the source of mischief as quickly as possible, to avoid a prolonged search and a second incision. This desirable end is not to be attained in every case by making the incision in any position. But in these desperate illnesses where the avoidance of delay and of difficulties is the very condition of success, the incision which hits the mark in the majority of cases is the one that

will give the best aggregate of results and should be generally adopted, even though in individual cases it may be found wanting. If the surgeon makes a probable diagnosis he usually explores over the suspected area. If he cannot, he should explore over the area which in the acute abdomen is *always* to be suspected.

The oesophageal opening of the stomach is situated behind the seventh costal cartilage of the left side, about one inch from the sternum. Drop a perpendicular line, which for purposes of reference may be called (a), from this point to Poupart's ligament. Next, draw a line, called in the same way (b), from the right anterior superior iliac spine perpendicularly upwards to the lower border of the thorax. Within the area bordered by these two lines almost every acute abdominal crisis either must occur, or, as a matter of fact, does occur. It may be termed the "area of acute abdominal conflux."—It may be subdivided into an upper and a lower compartment by a horizontal line at the level of the umbilicus. The incision which will lay bare this area is a vertical one midway between the lines (a) and (b)—i.e., one just about the outer border of the right rectus. This may therefore be called the "incision of incidence" in the acute abdomen.

The factors in the production of the acute abdomen will now be briefly considered with reference to their locality. It is assumed that a strangulated hernia at one of the rings has been excluded. This usually presents no difficulty. These factors may be divided into three classes: (I.) those that can only occur within the area; (II.) those that may occur either within or without the area; and (III.) those that can only occur without the area.

Class I. (those that can only occur within the area) includes (1) appendicitis (excluding the rare condition transposition); (2) pericæcal hernia; (3) right ruptured pyosalpinx; (4) right ruptured ectopic gestation; (5) acute gall-bladder complications, suppurative cholecystitis and cholelithiasis, perforation, and gangrene; (6) perforation of a duodenal ulcer; (7) perforation of a gastric ulcer; (8) hernia through the foramen of Winslow; (9) right diaphragmatic hernia; and (10) hernia duodeno-jejunalis, the mouth of the fossa, the seat of strangulation, being at the junction of the duodenum and jejunum and looking to the right.

Class II. (those that may occur either within or without the area) includes:—1. Intussusception. According to Warren in about one-third of all cases no palpable tumour is present. Out of 109 consecutive cases occurring at St. Thomas's Hospital 75 were ileo-cæcal, 12 enteric, 5 ileo-colic, 5 colic, and 12 were double or unusual forms. Wiggin found in 103 cases 89 per cent. of the ileo-cæcal variety. Intussusception, therefore, does occur far more frequently within the area than without it. 2. Obstruction by Meckel's diverticulum. This is usually attached to the lower ileum within three feet of the ileo-cæcal valve. It is situated, therefore, usually within the area. 3. Obstruction by bands and adhesions. These are usually the result of previous attacks of localised peritonitis. Such peritonitis has its most frequent origin in inflammations of the appendix, Fallopian tubes, gall-bladder, duodenum and stomach (ulcer), peritoneum, mesenteric glands, and intestine (tubercle). Post-operative bands are excluded, because in these cases the surgeon would not be without a clue, which in this paper is supposed to be wanting. It will be seen that the great majority of organs usually giving rise to localised peritonitis and the consequent formation of bands are situated within the area. Of the 101 cases of strangulation in Fitz's table (which includes: adhesions, 63; vitelline remains, 21; adherent appendix, 6; mesenteric and omental slits, 6; peritoneal pouches and openings, 3; adherent tube, 1; and peduncular tumour, 1), in 67 per cent. the strangulation was in the right iliac fossa—i.e., within the lower area of acute abdominal conflux. 4. Obstruction of the intestine by a foreign body (most commonly gall-stones, rarely enteroliths, worms, and tumours). The lower ileum is the narrowest part of the intestinal tract. Foreign bodies are, therefore, most frequently, as might have been expected, arrested there—i.e., within the area. Tumours of the bowel are usually malignant, occur in the large intestine, and most frequently give rise to chronic obstruction. Such tumours as fibromata, myomata, and lipomata are exceedingly rare. 5. Perforation of typhoid ulcers. This occasionally has taken place in the ambulatory form of the disease, when the patient was not suspected to be suffering from typhoid fever. Out of 362 cases in Harte's and Ashurst's series, in 73 per cent. the

perforation was found within 12 inches of the cæcum; next most frequently in the appendix; and, lastly, in the ascending colon, all positions within the area. In Harte's and Ashurst's table of operation for these cases the right iliac incision gives the lowest mortality. 6. Perforation of tuberculous ulcers. These ulcers are most commonly found in the ileum, cæcum, and colon. Should they perforate, they would do so in the majority of cases within the area. 7. In cases of chronic mechanical obstruction of the large intestine, due mostly to malignant disease in the sigmoid, splenic flexure, &c., perforation occasionally takes place somewhere on the proximal side of the growth. The most common situation for this is in the cæcum—i.e., within the area. 8. Volvulus and knots. The most common site of volvulus is the sigmoid flexure (50 per cent. in Fitz's table)—i.e., outside the area. The next most common sites are the cæcum and the lower part of the ileum, both within the area. 9. Twisting of an ovarian or fibroid pedicle. This may occur either within or without the area. A palpable tumour would be likely to be present in these cases. If not, the condition could probably be readily detected and dealt with from the right semilunar incision. 10. Gangrene due to embolism of the superior mesenteric artery or thrombosis of the mesenteric veins. In the former, if the embolus is arrested in the main vessel, the terminal portion of the ileum will at all events be involved, the length of intestine becoming gangrenous varying with the size of the embolus. The terminal portion of the ileum lies within the area. If the embolus be arrested in the right or middle colic artery the resulting gangrene will likewise take place within the area. 11. Strangulated diaphragmatic hernia. Though left diaphragmatic hernia is much more common than right, the hernial openings in this condition are generally found on either side close to the median line (the oesophageal opening gaps between the sternal and costal portions of the muscle and similar gaps between the lumbar and costal portions of the muscle). The mouth of the hernia will usually, therefore, be found within the area.

Class III. (those that can only occur without the area) includes: (1) volvulus of the sigmoid flexure; (2) inter-sigmoid hernia; (3) left ruptured pyosalpinx; (4) left ruptured ectopic gestation; and (5) left diaphragmatic hernia (rarely).

Many of the factors enumerated in the above table are exceedingly rare; others are common. Of the latter it will be seen, on referring to the tables given above, that a large number of them must originate within the area of acute abdominal conflux. They are appendicitis, acute gall-bladder affections, perforated gastric and duodenal ulcers, right ruptured ectopic gestation, right ruptured pyosalpinx, and less common gangrenous pancreatitis. Rare conditions, pericæcal hernia, hernia through the foramen of Winslow, right diaphragmatic hernia, and hernia duodeno-jejunalis (the mouth of the sac), must also occur within the area. Of the factors that may give rise to the acute abdomen either within or without the area we find as a matter of experience that all of them, with two exceptions (volvulus and twisted ovarian or fibroid pedicle) actually do give rise to it far more frequently within than without the area. Intussusception, obstruction by Meckel's diverticulum, obstruction by bands and adhesions, obstruction of the intestine by a foreign body, perforation of typhoid, tuberculous or stercoral ulcers, diaphragmatic hernia, and gangrene from embolism of the superior mesenteric artery, do occur far most commonly here. The only conditions that must occur outside the area are volvulus and knots and bands involving the left portion of the intestine, left ruptured ectopic gestation, left ruptured pyosalpinx, and the very rare condition inter-sigmoid hernia.

We may next separate our patients into two classes by a known factor—sex. In the case of a male, ectopic gestation, pyosalpinx, and twisted pedicles, ovarian or fibroid, are excluded. We thus arrive at the fact that every condition producing the acute abdomen, with the single exceptions of volvulus and the very rare complication inter-sigmoid hernia, either must occur within the area of acute abdominal conflux or, as a matter of fact, most commonly does so. If the patient be a woman the preponderance is not quite so overwhelming owing to the possible pelvic complications on the left side, which have been enumerated. But even here the excess is very large.

The practical conclusion from the above consideration is that in a case of the acute abdomen of doubtful origin the incision which will expose and give ready access to this area

is that of election. This incision lies in the right semilunar line and has been previously named the "incision of incidence." The usual practice is to make the incision in the mid-line below the umbilicus and to introduce the hand for the purpose of exploring the abdomen by touch. There is no doubt that with increased experience within the abdomen the tactile sense becomes educated and examination thereby becomes intelligent and purposeful. But all who are called upon to open the abdomen may not be in possession of the tactile skill, which practice alone bestows, and, moreover, even to those who have had large experience within the abdomen, an ounce of sight is worth a ton of touch. The actually seeing the condition enables us to take in the whole situation at once. Such information touch alone rarely affords. Moreover, the examination by touch in those cases in which exposure fails can be just as well conducted through an incision in the right semilunar as in the median line.

For these reasons the following routine is recommended as the operation of exploration in the acute abdomen of doubtful origin. An incision should be made, large enough to give plenty of room, just within the outer border of the right rectus, commencing about the level of the umbilicus and continued downwards. Turning the rectus inwards the peritoneal cavity is opened. By the aid of retractors the lower area of acute abdominal conflux is exposed. This should be explored first because the appendix is far the most common defaulter in the acute abdomen. In a series of 456 cases of the acute abdomen occurring at St. Thomas's Hospital during the years 1900, 1901, and 1902 37 per cent were due to the appendix and its complications. This incision will also give access to, if present, right ruptured ectopic gestation, right ruptured pyosalpinx, and pericecal hernia. It will in addition give information as to the state of the large bowel, whether empty or the reverse, in cases of obstruction and indicate whether the obstruction is in the large or small intestine. In those cases, too, where the general condition of the patient warrants no more than the establishment of an artificial anus this can be accomplished at the seat of election, the cæcum being used for this purpose if distended, and if collapsed a point as low down as possible in the ileum will be accessible, which is the indication in such cases. It will also in all probability expose an intussusception, obstruction by Meckel's diverticulum, obturation of the intestine by a foreign body, and perforation of typhoid, tuberculous, or stercoral ulcers. If the cause of the trouble is not in this area the hand can be passed into the incision and the umbilical ring and hernial rings on both sides, as well as the contents of the left pelvis, can be explored by touch. Should success not reward the surgeon's efforts the incision should be prolonged upwards, the rectus shelled out of its sheath, and the peritoneal opening enlarged into the upper area of acute abdominal conflux, the lower area already explored being packed off with gauze. Here he will obtain direct access to acute gall-bladder conditions, perforated duodenal and gastric ulcers, acute gangrenous pancreatitis, the mouth of a hernia duodeno-jejunalis, hernia into the foramen of Winslow, diaphragmatic hernia (usually), and probably bands and adhesions if not found in the lower area. To deal with some of these conditions, for instance, an ulcer near the cardiac end of the stomach, the incision would probably have to be extended inwards along the lower border of the ribs. Finally, if the cause is not discovered, which will be very unlikely, the hand can be introduced through the incision and the rest of the abdominal cavity explored by touch just as well as through a median incision. Of course, it hardly requires insisting that incidents occurring during the course of the exploration would in some cases modify this routine method. If, for instance, on opening the abdomen in the lower right quadrant free blood were found in the peritoneal cavity, the surgeon would naturally go down into the pelvis at once for a ruptured ectopic gestation. If, again, he found gas or stomach contents he would prolong the incision at once upwards, &c. All rules have their exceptions. The object of this paper is to indicate the general plan on which the acute abdomen should be explored and to demonstrate the method which is most likely to reward our efforts in cases which are always difficult. It is not contended that it must rigidly be adhered to in every case.

To sum up, the advantages claimed for this incision in comparison with the median incision are: 1. That it directly exposes to sight that part of the abdominal cavity which in

a large proportion of cases *must* contain the offending organ and which in another large proportion of cases do as a matter of fact do so. 2. That therefore in the large majority of cases it will enable the surgeon to deal directly with the offending organ and without the necessity for an second incision unless this be required for drainage. 3. That for these reasons it makes, in the majority of cases, for the avoidance of delay and difficulty, two essentials of success in these operations, and will therefore give the best aggregate of results. 4. That in the minority of cases, in which it fails to expose the offending organ, the abdomen can be examined by touch just as well through the right semilunar as through the median incision. 5. That in those cases of intestinal obstruction where the patient can bear no more than the establishment of an artificial anus it is close to the seat of election for this operation—the cæcum or lower ileum.

All surgeons who are much engaged with the acute abdomen must experience how frequently the condition producing it is encountered between the lines (a) and (b) within the area of acute abdominal conflux, how comparatively seldom to the left of (a). To expose the former is, therefore, I venture to submit, the clear indication. In a series of 53 consecutive acute abdominal illnesses, for which I have recently operated (except one which was under my care but in which the operation was performed by a London surgeon), no less than 33, or 62·2 per cent., almost certainly had their origin in the appendix. I say "almost certainly" because in a few of them, in which a localised abscess was present, the appendix was not removed, although it was practically assured that that organ was the source of the mischief. The remaining 20 were constituted as in the following table:—

Condition.	No.	Locality of mischief.
Ruptured ectopic gestation.	5	Three right, two left.
Acute double salpingitis.	1	—
Acute intestinal obstruction.	1	Band in right iliac fossa.
"	1	Gall-stone impacted at the ileo-cæcal valve.
"	2	Malignant disease of the cæcum.
Perforation of stercoral ulcer.	1	Cæcum.
Perforation of gastric ulcer.	1	Near cardiac end.
Acute intussusception without tumour.	1	Right iliac region.
Acute hæmorrhagic pancreatitis.	1	Swelling to the left of the median line.
Acute gall-bladder and bile-duct infections.	3	Right hypochondrium.
Acute suppurative peritonitis of doubtful origin.	3	Pus evacuated by right semilunar incision.

Dealing first with the last three in the series, in all of them pus was evacuated by a right semilunar incision, but two of them were so ill that no further procedure was possible. One from the history probably had its origin in the appendix; another was not due to appendix disease, as the appendix was exposed at the operation, but the cause was not ascertained. The third case was one of suppurative peritonitis in a man, where a most thorough exploration of the abdominal viscera on the lines indicated in this paper was conducted, but without result. The patient died the next day and a very careful post-mortem examination under my own supervision failed to indicate the origin of the mischief.

Excluding these three cases of doubtful origin we have in 14 out of 17 the source of trouble within the area of acute abdominal conflux, so that out of the whole series of 53 cases no less than 33, plus 14—i.e., 47, or 90 per cent.—occurred within this area, and in an additional three pus was evacuated from it, though the source of it could not be ascertained. Of the 53 cases, in 43 a certain or probable diagnosis was made and the incision was planned to meet their requirements. In the remaining 10 either no further diagnosis was made than that an acute abdominal crisis had occurred, requiring immediate surgical interference, or where a diagnosis was made as to the condition (acute obstruction, for instance) none was arrived at as to locality. These were cases of acute perforative appendicitis with general peritonitis (six), obstruction by a band (one), obstruction due to a gall-stone impacted at the ileo-cæcal valve (one), acute obstruction consequent on malignant disease of the cæcum

(one), acute intussusception without tumour or rectal hæmorrhage (one), and acute hæmorrhagic pancreatitis (one). In all of these, with two exceptions, the exploratory incision was made in the right semilunar line and exposed the source of the trouble at once. The exceptions were the case of hæmorrhagic pancreatitis, in which a swelling was present in the upper abdomen to the left of the median line and the incision was made over it; and one of the cases of suppurative appendicitis, in which no diagnosis was arrived at, and the incision was made in the middle line below the umbilicus by a London surgeon. It would have been better, as the case turned out, to have made it in the right semilunar line. The above brief analysis, though from the limited number of cases necessarily incomplete, confirms by actual practice the conclusion as to the semilunar incision being the correct one.

In conclusion, the acute abdomen should be explored early. It must be confessed that in spite of the advance in abdominal surgery during the past quarter of a century, reducing the mortality of operations performed in the cold stage, however severe, to almost insignificant proportions, the acute abdomen remains a *bête noire* with its high mortality. The reasons are not difficult to assign. They are difficulty in diagnosis, drugs, and delay. A patient is seized suddenly with acute abdominal pain, vomiting, and collapse. It may be nothing more than an acute colic. I have myself seen apparently very severe symptoms, indistinguishable in their onset from those of a perforated appendix, for instance, produced by the administration of a couple of colocynth pills. In an hour or two of course they disappeared. Probably every practitioner can recall experiences of acute abdominal symptoms, which caused him a few hours of grave anxiety as to what had happened, but the outcome of which demonstrated that his fears were unfounded. Like symptoms, on the other hand, may be due to a serious abdominal catastrophe, in which every hour of delay in opening the abdomen materially lessens the patient's prospect of recovery. Every acute abdomen, it goes without saying, should therefore be watched from hour to hour, with the determination ever uppermost in the practitioner's mind to summon the surgeon should improvement not rapidly set in. During this interval, if there be one, morphine should not be given if it can be avoided. But it cannot always be avoided, and in such cases the minimal dose which will meet the requirements of the case should be administered. If, as has been insisted upon over and over again, the necessity for a second dose arises it should be a golden rule to invite the surgeon to see the case first. When a patient is under the influence of morphine it is well-nigh impossible to gauge the magnitude of the disaster. A patient with a perforated appendix, as I have myself witnessed, may, under its delusive sway, sit up in bed, look cheerful, and say he feels all right, and his aspect and pulse may not indicate that he is not. If the initial symptoms do not rapidly abate (and morphine, if it has been administered, must be allowed for in estimating such abatement), or if after the effect of the drug is wearing off they recur, they point almost certainly to no passing or trifling condition but to one of the serious catastrophes requiring probably immediate operation. Should the practitioner not intend to operate himself then it is manifest that the sooner the surgeon sees the case in consultation with him the better, and inasmuch as the latter has to bear the responsibility of the result of the operation it is only fair to give him every chance of insuring its success. In case of failure it is generally thought and said that the patient died from the operation, whereas in reality in most cases it is the want of operation which has killed the patient. So long as a patient with the acute abdomen is given a trial of medical treatment first for two or three days, and then, when it is evident he is not going to get better, the surgeon is called in to operate, so long as this is a common practice the mortality will inevitably be high. It cannot be denied that during the last quarter of a century the surgeon has become greedy. He has become worse. He has become omnivorous, encroaching from all sides on the province of the physician, and the latter would be more than human if he felt no reluctance to part with his cherished preserves. This is the irony of the ever-swinging pendulum. A quarter of a century ago the surgeon was not required in the acute abdomen. He is required now. By a swing in the opposite direction it is safe to say that the physician of the future will get back his own, and possibly more than his own, in other fields owing to the discovery of methods less rude and

more scientific than the knife. But knowledge as at present vouchsafed to us has constituted the acute abdomen surgical affection. The most cursory glance at the fact concerned in its production must convince any practitioner how lucky it will be if the patient survives it without surgical aid. It is true that a patient after perforation of gastric ulcer may recover. There is proof on record that has occurred. It is true that intestine may slip under band and, after giving rise to acute obstruction, may slip back again; that a gall-stone blocking the bowel may pass *per vias naturales*; that a patient after being death's door from internal hæmorrhage owing to a ruptured ectopic gestation may recover. But it will not, I think, be questioned that the chances of such lucky terminations are infinitesimal compared with the prospect of recovery if a patient is operated upon and the lesion remedied before complications have arisen which from their nature must go far to negative the success of any operation, however skilfully and carefully performed.

AMYL NITRITE IN HÆMOPTYSIS.¹

BY GEORGE A. ORAOE-OALVERT, M.B. LOND.,
M.R.C.S. ENG., L.R.C.P. LOND.,

PHYSICIAN TO THE VALE OF CLWYD SANATORIUM, BUTHIN, NO
WALES.

THE occurrence of hæmoptysis is nearly always an alarming symptom both to the patient and his friends and the physician. The patient is usually very frightened especially if he has never had a hæmorrhage before. till then has apparently been in good health, though I have known of patients with considerable amounts of blood who have pursued their ordinary work afterwards till something or other has pulled them up and compelled them to consult their medical man. To the majority of physicians too, hæmorrhage is, I think, one of those symptoms that are glad to see the last of, for till recently our methods of appliances for its treatment have not been on the whole satisfactory, so much so that one writer remarks that "cessation of hæmorrhage after the exhibition of a drug is itself no proof that the effect was produced by the drug." In ordinary practice, by the time that the medical man reaches the patient suffering from hæmoptysis, the bleed if profuse, will probably have proved fatal, while if a slight the first alarming symptoms will have subsided the bleeding may be ceasing spontaneously. In sanatorium work, however, the physician is usually able to be called the very outset and has to be prepared to act promptly, even what appears to be only going to be a small hæmorrhage may rapidly increase and prove fatal in a few minutes as happened in a case that I shall mention presently. It being so, it follows that we should like to have available drug or drugs which will act promptly and effectively. Until recently we have had to be content with drugs which though theoretically of the correct therapeutic action—have been far from satisfactory, and perhaps largely so because of the difficulty of administration and because of their comparatively slow action.

It will be a long time before I forget the sense of helplessness that I felt in the case just referred to where the patient—a man with moderately advanced mischief in a fairly quiescent state, apparently in ordinary health—was upstairs one evening to his room and at once came again, spitting up a little blood and asked another patient whom he met to go for the doctor. My partner went once and found him sitting on the edge of the bed, coughing up blood freely, and by the time that I arrived he brought up a large quantity of blood and was almost unconscious and it was a puzzle to know whether to give morphine to try to check the cough and bleeding, or to give strychnine to try to stimulate him to cough up the blood already effused into the lungs. However, he died almost before anything could be done, but I have often wondered since—if he had been given an inhalation of nitrite of amyl as soon as he was seen—whether his life might not have been saved, or, at least, prolonged a little.

Of the drugs which are usually used in a case of hæm-

¹ A paper read before the Denbigh and Flint division of the N. Wales branch of the British Medical Association, Wrexham, Feb. 15th, 1907.

² Dr. W. E. Dixon. THE LANCET, March 24th, 1906, p. 626.

rhage—viz., ergot, adrenalin, morphine, calcium chloride or lactate—I do not think that any are of supreme value but there is no doubt that several may help considerably if there is time for them to act, though Dr. W. E. Dixon in a recent article already quoted says that “the tannins, adrenalin, digitalis, and its allies, ergot, veratrine, barium, and lead, are all worse than useless for hæmoptysis.” Morphine usually proves of some use but should be used with discretion. Its action in quietening a nervous, excitable patient, slowing and weakening the heart, and dilating the vessels, combined with its ease of administration hypodermically, is often of great value but at the same time must be remembered its action in depressing the respiratory centre and so checking cough, for it seems to me that it is often of doubtful value to check the cough, especially in those cases where there has been a fairly sharp hæmorrhage. For though to check the cough may undoubtedly help to check the bleeding, at the same time it tends to cause accumulation in the air passages of the blood already effused, and if the blood be retained it will almost certainly decompose and form a most favourable medium for the development of any number of septic and other organisms which will probably land the patient into septic pneumonia or a rapid extension of his tuberculous condition. So that it seems to me to be better—unless the patient is greatly alarmed and excited or the cough is irritable and useless—not to give morphine at all, or else to delay doing so until as much effused blood as possible has been coughed up. Meanwhile much may be done to calm an excited patient by giving directions quietly and telling him exactly what to do in restraining useless cough and in breathing regularly and gently.

Calcium salts—the best being perhaps the lactate—in profuse hæmoptysis are useless because of the time they take to act but may prove useful in cases where the bleeding continues for some days. The lactate is best given in one dose of 60 grains, repeated if necessary in a day or so.

The drug, however, which seems to me to be most valuable in practically all cases of hæmoptysis is nitrite of amyl. At first sight it appears to be madness to give a patient with a wounded and bleeding vessel a drug which acts powerfully as a dilator of vessels but—even though its action be only transient—it produces such an immediate fall in the general blood pressure by dilatation of the vessels throughout the body that the pressure at the bleeding point is lowered and there is time for clotting to take place and the hæmoptysis usually ceases almost instantly. Even if the pulmonary vessels are dilated the ill-effects are more than counterbalanced by the fall in blood pressure, but Dr. Francis W. E. Hare (who first suggested the use of nitrite of amyl) quotes in an article in the first number of the *British Journal of Tuberculosis* experiments which seem to prove that it has a direct vaso-constrictor action on the vessels of the pulmonary periphery in spite of a vaso-dilator action elsewhere. It may, however, be urged that this constriction of the pulmonary vessels is bad in that it must raise the blood pressure in those vessels, but this seems to be more than counterbalanced by the fall in general pressure, whereas in the case of adrenalin, ergot, &c., there is no corresponding fall in general pressure. Moreover, nitrite of amyl causes no reactionary pulmonary hyperæmia (after the anæmia), while adrenalin apparently does, for I have heard of a cyst being removed by a “bloodless” operation under cocaine and adrenalin and next day a large clot of blood being found in the place which the cyst had occupied. Again, nitrite of amyl has a further good point and that is the fact that it does not interfere with coughing and so does not place any obstacles in the way of the patient getting rid of the effused blood and hence it considerably lessens the risk of septic trouble later.

I now always carry three-minim capsules of amyl nitrite and as soon as I am called to a case of hæmoptysis break one and tell the patient to inhale it quietly and regularly and at the same time warn him of the feeling of fullness in the head it produces as I found this feeling had alarmed one or two patients. The bleeding usually stops almost at once, though the patient may go on coughing up clotted blood which has been already effused. After that, if the patient is excited or alarmed, or the lungs appear to be irritable, I may give a hypodermic of morphine. From my experience of its action, however, I believe that in nitrite of amyl we

have the best drug to administer first in any case of hæmorrhage.

The following are brief notes of cases which have been treated with nitrite of amyl and may be of interest.

CASE 1.—A youth, aged 19 years, with most of the right lung consolidated, without any cavities, had a slight hæmoptysis (about half an ounce) one evening. It ceased for the time being after inhaling three minims of nitrite of amyl, though for the next three days he brought up blood-stained sputum.

CASE 2.—This patient had advanced mischief in both lungs and had many hæmorrhages at various times. On March 1st he had a small sharp hæmorrhage which was followed during the next few days by several small attacks, all of which promptly yielded to inhalations of nitrite of amyl. He was placed on liquor calcoli chloridi and the blood gradually disappeared from his sputum. On May 8th he had another short hæmorrhage which yielded at once to amyl nitrite, though he continued to bring up bright coloured sputum for a couple of days, apparently from a recently formed cavity. On the 17th he brought up three-quarters of a pint of blood and this attack stopped after two capsules of amyl nitrite and morphine (quarter of a grain). On the next day at 5 P.M. he brought up two or three mouthfuls of bright blood which ceased after an inhalation. On the next day (May 19th) he started a profuse hæmorrhage and at once inhaled the contents of a capsule and was then given another by the nurse. When I arrived a minute or two later he appeared to be dying, though the bleeding had apparently ceased. His heart was beating irregularly and feebly and his pulse was scarcely perceptible. I gave him a quarter of a grain of morphine, and he revived and vomited a quantity of blood which with what he had coughed up came to two pints. There was no further hæmorrhage, but he died ten days later. In this case I am convinced that the nitrite of amyl saved him from immediate death on several occasions.

CASE 3.—This patient had a cirrhotic left lung of several years' standing, active mischief throughout the right lung, and a dilated irregular heart. He had seven attacks of hæmoptysis during three days (several being fairly sharp) and all yielded more or less promptly to inhalations of amyl nitrite. He died a day later from sudden heart failure.

CASE 4.—This patient had tuberculous mischief throughout the left lung and had three attacks of hæmoptyses. The first stopped at once with one inhalation, but the next two did not yield so promptly, perhaps because he did not have sufficient nitrite as he did not have the feeling of fullness in the head to the same extent as on the first occasion.

CASE 5.—This patient—a nervous, excitable man—had several attacks of hæmoptysis at intervals of a few days which were all fairly promptly checked by inhalations of nitrite of amyl, though he sometimes continued to bring up brightly coloured sputum for a short time afterwards.

In all there are about 22 attacks of hæmoptyses occurring in five patients, and in the whole of them the bleeding ceased at once or was remarkably diminished directly after the administration of the nitrite of amyl, so that it seems impossible not to ascribe the good effects to this drug.

Ruthin, North Wales.

ASEPTIC AND SEPTIC MIDWIFERY AT THE LIVERPOOL WORKHOUSE HOSPITAL.

BY WILLIAM ALEXANDER, M.D.R.U.I.,
F.R.O.S. ENG.,

VISITING SURGEON TO THE HOSPITAL.

At the Liverpool Workhouse Hospital the obstetric wards are under the charge of the visiting surgeon and this is the reason that a general surgeon like myself reports the obstetrical work done in that institution during 1906. Being a surgeon, I look at obstetrics from a surgical point of view, and I consider the ragged, roughened area on the internal surface of the uterus that is left after a confinement to be for all practical purposes a *wound*, for which nature has provided an aseptic treatment of an unrivalled character, and one which meddlesome midwives do their best to upset, but which true obstetricians more and more respect. When sepsis does occur the treatment is pure surgery, modified by the position of the wound, and so-called puerperal fever is

* Ibid.

is no sense of the term a fever such as the eruptive or continued fevers are, but is a *round* fever and should be treated as such.

I shall enter no further here into these important questions, but after this brief confession of faith will proceed to describe under what conditions labours are attended at Brownlow Hill, the results of such treatment, and finally describe our treatment of some septic cases that were sent in by the medical officer of health and the measure of success which we attained by such treatment. In conclusion, I will offer some suggestions as to the management of obstetric cases in private practice amongst the poorer classes, based on an experience of many years. A thorough system of aseptic surgery is in force in the surgical wards of the workhouse hospital and this system has been gradually introduced as far as possible into the obstetrical department. These wards are in a wing of the general hospital and form part of an old building that is very much out of date for hospital purposes. The life of the old building has been prolonged up to the present only by the careful and strict use first of the antiseptic system of surgery and now of the aseptic system. Had the older systems of surgery been in vogue the whole hospital would have been pulled down long ago as unhealthy and unsuitable. We receive no assistance, therefore, from structural arrangements, but whatever success we obtain is in spite of obsolete hospital construction. Whenever a patient is admitted to the wards (which form also a training school for midwives and monthly nurses) the nurse to whom the patient is allotted by the superintendent midwife washes her hands in soap and water, scrubs them well, and soaks them for three minutes in a solution of perchloride of mercury, 1 in 1000, and proceeds to ascertain if the patient is in labour or not. If not in labour she is sent to a division of the workhouse to await that event, sleeping every night in a room adjacent to the lying-in ward. Should she be in labour her temperature is taken, and if above normal the patient is sent to another division to be confined, being attended there by the lying-in nurses. If the temperature is normal and should time allow, the patient is bathed, vulvar hair is removed, and the external parts are well washed with ethereal soap. She is dressed in warmed and thoroughly cleaned night clothes and put to bed. The mattress of the bed contains clean straw that has not been used for a bed before. The vagina is now washed out with a quart of solution of perchloride of mercury (1 in 1000). After the completion of the cleansing process the patient is given some warm milk to drink and is ready for the process of labour. The above is the usual proceeding modified by the exigencies of each case. Having again washed her hands the nurse brings a basin of izal (one drachm to the pint) and sets it beside the bed so that she may dip her hands in it frequently during the labour. We tried the Condy and oxalic method of cleansing the nurses' hands, and the surgeons still use it in operative cases, but with the nurses who have to cleanse their hands so frequently each day it caused so much irritation that it had to be abandoned and milder methods adopted.

As few digital examinations are made as possible, but the patient is closely watched both by the eye and finger for any sign of abnormality during confinement. This is reported to the head midwife who if necessary sends for the senior house surgeon or one of the two house surgeons who are always on the premises. After the labour is over a piece of iodoform-gauze is applied to any abrasions or lacerations and a sterilised pad of cotton wool inclosed in gauze is applied to the vulva. This is changed about four times a day or oftener if necessary. At the end of 24 hours the patient is removed from the labour ward to the lying-in ward, where another new and clean bed awaits her, having a small crib at the side of the bed for the baby. At the end of a week she is removed to the convalescent ward to a third new clean bed where she remains till her discharge, which generally takes place about a fortnight after the confinement. Should any patient become decidedly feverish from any cause she is removed at once from the obstetric department and treated by nurses having no connexion with the obstetric wards. Patients delivered on the street on their way to the wards are not admitted into the obstetric wards as far as possible from all dangers of infections, either puerperal or general. No visiting by friends is allowed in the obstetric wards. The results of all these precautions for the year ending 1906 are given below. Total number of labours, 401; married, 218; single, 183; primiparae, 157.

Admitted in labour, 248; from workhouse, 148; and from lock, 5. Maternity mortality, 3—viz., the forty-sixth, the 181st, and the 357th case.

Causes of maternal deaths.—Case 46, a primipara, aged 22 years, admitted with albuminuria and eclampsia. Delivered of twins, fits continued after labour, and in spite of treatment ended in coma and death. Case 181, aged 31 years, was admitted blanched and bleeding from placenta prævia. The bleeding had been going on for 24 hours. Version was performed and the child delivered. She had an attack of a low form of pneumonia and phlebitis from which she never recovered, but died after repeated relapses on July 18th, exactly a month after; no necropsy was allowed. Case 387, aged 23 years, was admitted from lock with gonorrhœal discharge and secondary ulceration of the labia. She was delivered naturally and easily, the temperature on admission being normal. The next morning she had a rigor, double pneumonia set in, and she died from that disease three days afterwards. The uterine organs were normal as verified by post-mortem examination.

Births.—Males 203, females 204; twins six times.

Infantile mortality.—Debility after birth, 21; stillborn, 7; decomposed and premature, 31.

Presentations.—Head, 377; breech, 14; foot, 7; transverse, 5; brow, 1; and face, 3. Cord prolapsed twice with head presentations.

Operations.—Forceps, 13; version, podalic, 6; cephalic, 3.

Complications, maternal.—Accidental hæmorrhage, 7; albuminuria, 6; placenta prævia, 6; eclampsia, 3; adherent placenta, 4; and pneumonia, 1. In 2 cases of placenta prævia the head came down and labour terminated naturally.

Complications, infantile.—Ophthalmia neonatorum, 1.

Mothers sent to other wards on account of being febrile, 4.

During the year 17 pupil midwives were trained here and they all succeeded in passing the Central Midwives Board at their first entrance. Nine probationers were allowed a month's practice in the obstetric wards and will be able to act as monthly nurses should occasion arise in their general nursing practice. All the pupil midwives have had two years and nine months' training in the general medical and surgical wards before they enter upon the three months' training in the obstetric wards by which they complete their three years' hospital training. Our pupil midwives consequently possess an amount of professional knowledge that few pupil midwives at the beginning of their period of training possess and are consequently much easier to teach.

I will next give a summary of cases of puerperal sepsis treated in the Workhouse Hospital, Liverpool, during 1906, all of which, except four, were admitted from the city of Liverpool, having been notified as puerperal fever—viz., 32 cases with 11 deaths, or a mortality of 36·5 per cent.

CASE 1.—Multipara, aged 33 years, admitted from town Dec. 31st, 1905. Confined nine days before admission. Comatose; purulent discharge from uterus. Treatment: uterine and vaginal douches; ergot, quinine, oxygen, stimulants. Result: death, Jan. 5th, 1906. No post-mortem examination.

CASE 2.—Primipara, aged 22 years, from workhouse lying-in, two days after confinement. Ruptured perineum. Temperature 105° F. from sixth to tenth day after confinement. Discharge from uterus. Abscess in left broad ligament, opened per vaginam. Treatment: uterine and vaginal douches; ergot, quinine, and strychnine. Discharged well, April 24th, 1906.

CASE 3.—Multipara, aged 39 years. Admitted from town Jan. 24th, 1906, ten days after abortion caused by a fall downstairs, followed by severe flooding. On admission her temperature was 104° F. There were a purulent uterine discharge and general septicæmia. Treatment: uterine douches, curetting; ergot, quinine, strychnine, stimulants. Result: death Feb. 7th, 1906. No post-mortem examination.

CASE 4.—Multipara, aged 42 years. Admitted from town Feb. 9th, 1906, 17 days after abortion; uterine hæmorrhage daily since. Patient in state of collapse, constant vomiting, and diarrhoea. Purulent and hæmorrhagic discharge from uterus. Treatment: uterine and vaginal douches; ergot, quinine, strychnine, stimulants. Result: death Feb. 13th, 1906. No post-mortem examination.

CASE 5.—A woman, aged 25 years. Admitted from town March 5th, 1906, 12 days after abortion; three or four months pregnant; severe hæmorrhage for three days; purulent uterine discharge; double pneumonia. Treatment: uterine and vaginal douches, poultices; ergot, quinine, strychnine, digitals, stimulants. Result: death March 6th, 1906.

CASE 6.—Multipara, aged 40 years. Admitted from town March 6th, 1906, six days after confinement; attended by midwife. Purulent uterine discharge; pneumonia, with a low temperature. Treatment: uterine and vaginal douches; ergot, quinine, strychnine, am. carb., and stimulants; poultices for pneumonia. Result: discharged well March 13th, 1906.

CASE 7.—Multipara, aged 36 years. Admitted from town March 10th, 1906, two weeks after confinement; attended by midwife and medical man. Purulent uterine discharge beginning ten days after confinement. Treatment: uterine and vaginal douches; ergot, quinine. Result: discharged well March 26th, 1906.

CASE 8.—A woman, aged 38 years. Admitted from town March 23rd, 1906, ten days after confinement; attended by a midwife. Purulent

uterine discharge. Treatment: douches of weak creolin; ergot and quinine. Result: discharged well April 9th, 1906.

CASE 9.—Multipara, aged 24 years. Admitted from town April 9th, 1906. Confined three weeks before. Quite well a week when healthy discharge stopped and fever and flooding and finally pneumonia set in. On admission her temperature was 105° F. and the pulse was 120. Pneumonia and purulent uterine discharge. Treatment: douches, poultices; ergot, quinine, strychnine, stimulants. Result: discharged well.

CASE 10.—Multipara, aged 30 years. Admitted May 30th, 1906, four days after confinement. Purulent uterine discharge, vomiting, pneumonia. Attended by a midwife. Treatment: douches, poultices; ergot, spiritus ammoniac aromaticus, quinine, stimulants. Result: discharged well June 13th, 1906.

CASE 11.—A woman, aged 25 years. Admitted from town June 1st, 1906, one week after confinement; was attended by midwife. Purulent uterine discharge, melancholia, bronchitis. Treatment: douches, poultices; ergot, quinine, strychnine, stimulants. Result: discharged cured June 24th, 1906.

CASE 12.—A woman, aged 22 years. Admitted from workhouse lying-in July 11th, 1906. Confined 24 hours of very decomposed child. Purulent uterine discharge. Temperature 102° F. Treatment: douches; ergot, quinine, stimulants. Result: discharged well July 21st, 1906.

CASE 13.—Primipara, aged 21 years. Admitted from town June 5th, 1906, with a diagnosis of puerperal fever two weeks after confinement; was attended by midwife. Temperature 105° F.; pulse 123. Purulent hemorrhagic uterine discharge. Pleuro-pneumonia, vomiting, but no peritonitis. Treatment: douches, poultices; ergot, quinine, strychnine, atropine, ammonia, stimulants. Result: death June 14th, 1906. No post-mortem examination.

CASE 14.—Primipara, aged 20 years. Admitted from town July 7th, 1906, 12 days after confinement; attended by midwife. Became febrile on third day—i.e., nine days before admission. Purulent uterine discharge. Treatment: douches; uterus packed with cyanide gauze; ergot, quinine. Result: discharged cured July 19th, 1906.

CASE 15.—Primipara, aged 22 years, admitted from town 12 days after confinement. Temperature 103° F.; some delirium. Purulent discharge from uterus, thick, yellow, and offensive. Treatment: uterine douches; ergot, quinine. Result: discharged well, August 11th, 1906.

CASE 16.—A woman, aged 37 years. Admitted from town August 27th, 1906. Said she had an abortion two months ago. Pale and weak. Treatment: ergot and douches. Result: discharged well Sept. 13th, 1906.

CASE 17.—Primipara, aged 19 years. Admitted from town Sept. 13th, 1906, ten days after confinement. Pulse 104; respirations 29. Delirious and noisy. Purulent uterine discharge. Diarrhoea, vomiting. Bronchitis. Treatment: uterine douches, stupes; ergot, quinine, stimulants. Result: discharged well Oct. 18th, 1906.

CASE 18.—A woman, aged 23 years. Admitted from town Oct. 15th, 1906, ten days after confinement; attended by a midwife. Temperature 103° F.; pulse 116; respirations 44. Purulent hemorrhagic discharge, vomiting, bronchitis. Treatment: douches, poultices; ergot, quinine, strychnine, morphine, stimulants. Result: discharged well Nov. 9th, 1906.

CASE 19.—Multipara, aged 36 years. Admitted from town Oct. 9th, 1906, 16 days after confinement; attended by midwife and medical man. Purulent discharge, semi-comatose, bronchitis, albuminuria. Treatment: douches, poultices; ergot, quinine, strychnine, stimulants. Result: discharged well Nov. 6th, 1906.

CASE 20.—A woman, aged 24 years. Admitted from town Oct. 23rd, 1906, nine days after confinement; attended by midwife and medical man. Purulent hemorrhagic discharge from uterus, diarrhoea, vomiting. Treatment: douches, stupes; ergot, quinine. Discharged well Nov. 8th, 1906.

CASE 21.—Multipara, aged 41 years. Admitted from town Oct. 18th, 1906, six days after confinement; attended by midwife and medical man. Temperature 103° 40' F.; pulse 132; respirations 28. Rupture of perineum, phlebitis, purulent discharge, vomiting, diarrhoea. Treatment: douches, stupes, linimentum belladonnae to legs; ergot, quinine, strychnine, digitalis, stimulants. Uterus curetted and packed with gauze. Glass tube left in uterus for one week. Result: discharged well Dec. 23rd, 1906.

CASE 22.—Multipara, aged 34 years. Confined two days before admission. Temperature 102° F. Vaginal discharge hemorrhagic and offensive. Pain in abdomen. Treatment: stupes, douche; quinine. Result: discharged well Oct. 19th, 1906.

CASE 23.—A woman, aged 28 years. Admitted from workhouse lying-in, Nov. 24th, 1906, where two days before she was delivered of decomposed child; attended by pupil midwife. Purulent discharge, vomiting, diarrhoea, bronchitis. Treatment: douches, poultices, stupes; ergot, quinine, digitalis, strychnine, stimulants. Glass drainage-tube in uterus for one week. Discharged well, Jan. 2nd, 1907.

CASE 24.—Multipara, aged 38 years. Admitted from town Nov. 16th, 1906, eight days after confinement; attended by midwife. Purulent discharge, bronchitis; looked starved. Treatment: douches, stupes; ergot, quinine, strychnine, digitalis, stimulants. Discharged well Jan. 8th, 1907.

CASE 25.—A woman, aged 29 years, admitted from town Nov. 28th, 1906, very weak and ill, 12 days after confinement; attended by midwife. Temperature 102° F.; pulse 133; respirations 32. Purulent hemorrhagic uterine discharge, vomiting, diarrhoea, bronchitis. Treatment: douches, poultices, stupes; ergot, quinine, strychnine, stimulants. Result: discharged well, Dec. 28th, 1906.

CASE 26.—Multipara, aged 30 years. Admitted from town Dec. 4th, 1906, five days after confinement; attended by a midwife. Patient in a state of collapse, delirious, cyanosed. Purulent discharge, peritonitis. Temperature 104° F.; pulse 166; respirations 36. Treatment: douche, poultices, stupes; strychnine, quinine, digitalis, stimulants. Result: died nine hours after admission. No post-mortem examination.

CASE 27.—Primipara, aged 22 years. Admitted from town Dec. 5th, 1906, seven days after confinement; attended by midwife. Delirious, badly lacerated. Purulent hemorrhagic discharge. Temperature 104° F.; pulse 160; respirations 48. Treatment: douches, stupes; nutrient enemata, ergot, quinine, strychnine, digitalis, stimulants. Result: death Dec. 7th, 1906. No post-mortem examination.

CASE 28.—A woman, aged 28 years. Admitted from town Dec. 5th, 1906, ten days after confinement; attended by midwife. Delirious;

abdomen distended, purulent discharge from uterus, bronchitis. Temperature 104° 60' F.; pulse 134; respirations 33. Treatment: douches, stupes, poultices; ergot, quinine, strychnine, digitalis, stimulants. Result: death Dec. 11th, 1906. Post-mortem examination, purulent peritonitis.

CASE 29.—A woman, aged 31 years. Admitted from town Dec. 11th, 1906, five days after confinement; attended by midwife. Vomiting, diarrhoea, double pneumonia, purulent discharge from uterus. Temperature 103° 80' F.; pulse 124; respirations 36. Treatment: douches, poultices, steam tent; ergot, quinine, strychnine, digitalis, stimulants. Death Dec. 14th, 1906. Post-mortem examination, septic uterine double pneumonia.

CASE 30.—Multipara, aged 32 years. Admitted from town Dec. 13th, 1906, three days after confinement; attended by midwife. Vomiting, abdomen distended and tender, purulent hemorrhagic discharge from uterus, bronchitis. Treatment: douches, stupes, poultices; ergot, quinine, strychnine, digitalis, stimulants. Result: death Dec. 15th, 1906. Post-mortem examination, purulent peritonitis.

CASE 31.—Multipara, aged 27 years. Admitted from town Dec. 17th, 1906, six days after confinement. Diarrhoea, vomiting, pain in abdomen, purulent discharge from uterus, right basal pneumonia. Treatment: douche; ergot, quinine, strychnine, digitalis, ether, alcohol. Valentine's meat juice hypodermically. Result: death Dec. 17th, 1906; no post-mortem examination.

CASE 32.—From our own lying-in and recorded in our maternal mortality.

For the notes of these cases I am indebted to Dr. John T. Moore, resident medical officer, to whose careful douching and unfailing assiduity the saving of the lives of several of these poor women may be justly attributed.

Considering the class of woman confined at the Liverpool Workhouse Hospital, the results of the year's work in the obstetrical wards are about as good as we can reasonably expect. A study of the three maternal deaths will show that none of them can be laid at the door of the hospital, but were all cases with serious complications that often lie beyond the powers of medical science. The obstetrical wards of the Liverpool Workhouse have always been remarkable for their low maternal mortality, and thanks to aseptic midwifery this low mortality is not only maintained but is placed on a much surer foundation than formerly. At intervals in the past, though rarely, we had to evacuate our obstetrical wards and flee to a remote part of the building for a time until the fever-stricken wards were purified. We have not had to beat a retreat for many years and while the aseptic system is maintained as at present we do not expect any such retreat to be ever necessary. Obstetric wards can now compete favourably with private midwifery practice, as 0.74 per cent. is a very creditable mortality amongst the lowest class of mothers.

When a patient after confinement in our obstetric wards becomes feverish she is removed to an isolation ward not connected with our lying-in ward. Here if the pyrexia survives movement of the bowels or if the lochia are at all affected the uterus is douched out with perchloride of mercury succeeded by boric lotion. This operation is always performed by one of the medical staff. It is an operation requiring skill and judgment and should not be undertaken by most nurses. Quinine and ergot are the medicines we use in order to produce uterine contraction and to control pyrexia and the treatment is generally rapidly successful. These attacks of pyrexia mostly occur where decomposed children are brought forth and such cases are very amenable to treatment. Sometimes a single douching is all that is necessary. Sometimes two or three are required, but rarely more in our own cases. In some cases, both of our own and of the outside cases, the uterus did not drain satisfactorily and the temperature soon rose again after douching, the os closing and the flaccid walls of the womb that have lost their contractile force lie together harbouring pools of septic material. In two such cases it will be noticed that we inserted a drainage-tube into the uterus with a most beneficial effect. In another case we packed the uterus in double cyanide gauze, in another case we curetted, in another we opened a broad ligament abscess, and by following up the lesions from point to point on surgical principles in this way we certainly diminished the mortality very materially.

I have given a brief summary of 28 cases admitted from town to our hospital wards, most of which were admitted by the orders of the medical officer of health. Some of these were moribund on admission and died a few hours after. Others were hopeless, although they lived for two or three days after admission, but in not one of these cases, although in nearly all of them the uterus was septic, did we have any history of the uterus having been washed out before admission. In several of the cases where the condition of the patient was sufficiently alarming on admission the thorough washing-out of the uterus acted like a charm, and I suspect that many of the

saved by this very simple procedure. But the use of the term "puerperal fever" seems to produce a feeling of mystery and of dread in regard to the poor sufferers, inasmuch that medical men as well as midwives avoid close contact or even any connexion with a puerperal case. The disease is looked upon in the same way that scarlet fever and erysipelas are looked upon, and the only desire is to get rid of the patient as soon as possible. When asepsis fails in an operation wound the surgeon does not act in this manner. He opens up the wound, drains it, or washes it out with an antiseptic, taking care, by the use of gloves, antiseptics, &c., that his hands and dress are not polluted through his attention to such a case. The same course could, and should, be carried out in obstetrics. But it must be carried out by medical men, not by midwives. It seems to me that all the midwives of a district should be under the supervision of a medical man whose attention should be called to all cases of pyrexia in the lying-in period and to whom all confinements in his district should be reported each morning as they take place, and for whose well-being he would be considered responsible. He should be well remunerated for his services and it should be understood that his duty was to ascertain and to remove all preventable causes of puerperal mortality. He would guide and encourage midwives in their efforts to carry out aseptic midwifery. At present punishment by suspension is what the midwife has to fear, but this only occurs in flagrant cases, especially where death has occurred, and is a poor satisfaction to mourning relatives, and may be hard on the midwife who perhaps tried to obtain the help of a medical man but could not. The Midwives Act is defective in that it does not afford to the poor honest women of the country anything like as complete facilities in their confinements as those which the Poor-law affords to the pauper mothers who are confined under its patronage.

Liverpool.

A CASE OF MULTIPLE CIRCUMSCRIBED LIPOMATA TREATED WITH ETHYLATE OF SODIUM.

By AGNES F. SAVILL, M.A. ST. AND., M.D. GLASG.,
M.R.C.P. IREL.

ASSISTANT PHYSICIAN TO ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN, LEICESTER SQUARE.

The following case of multiple circumscribed lipomata is of interest owing to the remarkable improvement under treatment.

The patient, a male, aged 31 years, came under my care at the hospital in June, 1903, complaining of "swellings under the skin" with considerable itching over some of them.

History of the "swellings."—In 1895, when the patient was 24 years old, he noticed a swelling somewhat smaller than a cherry on the flexor aspect of the right forearm. It itched a good deal, and as it slowly increased in size he went to Guy's Hospital, where it was excised. About a year later a second swelling appeared on the flexor aspect of the left forearm. So far as the patient can tell, no other swelling became visible till 1900 (i.e., nearly four years later). Between 1900 and 1903 they rapidly increased in number on the arms, legs, and trunk, and the larger ones caused itching.

Condition of swellings in June, 1903.—The swellings numbered between 17 and 20; the precise number was unfortunately not noted at the time because it was not expected that they would soon respond to treatment. The swellings were only roughly symmetrical in position and were situated immediately beneath the skin. Most of them were freely moveable and could be picked up between the finger and thumb; the older and larger ones appeared to have prolongations downwards into the muscular tissue. They varied in size from a threepenny-piece to a five-shilling-piece in diameter; the skin above them was raised about half an inch to an inch above the surrounding skin. The largest was not quite as large as an ordinary hen's egg and the smallest felt like a pea; many were flattened like an almond. The larger swellings had one or two pea-sized satellites in their vicinity. The swellings were hard and the skin above them showed no puckering when pinched up; they had a definite circumscribed outline and were not

lobulated. The skin over the older tumours was pink, with dilated venules visible to the naked eye. The tumour which had appeared in 1896 was very firm and of about the size of an almond; it was excised and examined microscopically, and proved to be of typical lipomatous structure.

Family history.—The patient had five brothers and four sisters. Two of the sisters died young; one is mentally deficient. One brother, aged 25 years, developed a "swelling" in 1905, but I have not seen him.

General health.—The patient had measles in childhood. In 1896 he had scarlet fever. He never had rheumatic fever. There was no history of syphilis, but he had a soft chancre in 1895. He was of average height, with a short neck and broad chest. There was no obesity. The heart and lungs appeared to be normal; the liver edge was just palpable on deep inspiration. The patient regarded himself as enjoying average health but there were about him signs of defective vascular tone, unmistakable to an experienced eye. The skin showed irregular mottling over almost the whole of the body. This mottling is visible in many individuals with defective circulation during cold weather but this patient showed the condition even on a warm day. All along the costal margin of the thorax there were telangiectases. The facial contour varied from day to day, having a flabby appearance when the patient felt "slack" and at such times the orbital fissure became narrowed, although no definite oedema beneath the eyes was ever seen. Every physician recognises this marked variation of the facial contour in subjects of what, for want of knowledge of the cause, we term deficient vascular tone. The extremities were frequently blue and swollen; the finger ends were inclined to be bulbous. The patient said that after a heavy meal, especially on a cold day, his ears and fingers up to the knuckles often became white and numb. He had been accustomed to take from three to six glasses of beer daily since the age of 20. He took spirits at times but had never been a hard drinker.

Treatment.—1. *Local treatment* consisted in painting the skin over each swelling with ethylate of sodium. At first this was done once a week but after a month the patient in his zeal exceeded his instructions and began to paint the skin daily. This set up inflammation and he developed a superficial ulcer over the largest lipoma, situated just above the right buttock, and redness and tenderness over several others. This was readily soothed down and the patient was instructed to paint the swellings two or three times weekly till the skin should become reddened, then to leave off local treatment until the skin returned to its normal condition, when the application might again be resumed. These directions were faithfully carried out until the early spring of 1906. He was then ordered to massage and rub the remaining lipomata and to douche them with as hot water as he could tolerate. 2. The *general treatment* was perhaps as important as the local treatment. A testotal regimen was prescribed. At first the diet was regulated in order to improve the dyspepsia but after a few months no restrictions were placed upon the diet. Active exercise in the form of bicycling had always been a favourite pastime with the patient and he was encouraged to continue the habit more regularly. In the spring of 1904 he began to practise deep breathing exercises and Swedish movements and has gradually increased these, practising them morning and evening. The constipation has been treated on the usual lines of diet, exercise, and pills of aloin with nuxvomica. Various tonics containing strychnine or nuxvomica, quinine, phosphoric acid, and iron were given at intervals from 1903 to 1906. In May and June, 1904, thyroid (2½ grains three times a day) was tried but had to be omitted because of the "clammy hot attacks" he suffered from whenever he took it regularly. In March, 1906, he was put on 20-grain doses of calcium chloride three times a day with the object of reducing the blueness and swelling of the fingers during the cold spring winds. He continued to take this from time to time till the warm weather of summer; it did not affect the remaining lipomata but it improved his general health and made him feel "braced up."

Effects of treatment.—No fresh tumour appeared after the commencement of treatment although between 16 and 19 lipomata had appeared within the three preceding years. A marked diminution in the size of the softer lipomata was noticed within a few months from the beginning of treatment, and by November, 1904—i.e., in less than 18 months—only 12 lipomata could be found, the smallest tumours having entirely disappeared. The remaining dozen very slowly but very steadily decreased in size. To-day (March, 1907)

on looking at the surface of the body of the patient there is only one slight swelling visible to the eye over a lipoma which is situated on the extensor aspect of the right thigh. It is only after most careful palpation that ten swellings can be discovered in the sites where, three years previously, there existed prominent tumours. Four of these remaining lipomata give to the examining finger a sensation as of a flat bean situated in the muscular tissue (being impalpable except on picking up the muscular tissue); six are not larger than a pea and are equally deeply situated and difficult to palpate. Several fine cicatricial areas are present over them, the result of the over-zealous preliminary treatment. The general health is much improved; the skin is less mottled, the eyes are bright, the lethargy and dyspepsia have vanished, and the movements are more alert. The telangiectases along the costal margin are still present but have not increased.

Previously recorded cases.—The literature on this subject is more scanty than would be expected. Surprised at the good result of treatment in my case I looked up the bibliography of multiple lipomata and found it consisted largely of short descriptions of cases of diffuse lipomata, the majority of whom had been exhibited at the medical societies. There was little reference to treatment. Previous to the introduction of antiseptics there are several interesting records of treatment in the French medical journals. The writers point out the usefulness of their methods of treatment, by which "all bleeding is avoided, and above all, erysipelas, which sometimes leads to death." After antiseptics rendered excision free from danger, there is but little further record of other than surgical treatment for lipomata. In 1839 Leviez¹ mentioned a case of a large fatty tumour under the chin which resisted all liniments, but after pustulation had been induced by friction with a certain pomade a cure ensued. In 1859 Legrand² described a method of linear cauterisation by zinc chloride, followed by application of caustics to the exposed tumour. He admits the painfulness of the procedure, but praises its safety. In 1863 Dr. Saul³ reported a case of multiple tumours which improved slightly under potassium iodide in doses of six grains three times a day. The tumours appeared to be of a lipomatous nature, but no microscopical examination was made. In 1872 Mr. J. Gay⁴ described a case of multiple lipomata which resembled my case more than any other description I have met with. The tumours were firm and hard, with well-defined outline, situated immediately beneath the epidermis. They occurred in a stout middle-aged man who suffered from dyspepsia and cold extremities. Under a course of treatment directed to the improvement of the general health and frequent hot baths (120° to 130° F.), given with the aim of liquefying the fat and so promoting its absorption, many of the tumours disappeared and the hard ones became softened. In 1881 Dr. Pritchard⁵ reported a case of multiple symmetrical lipomata, averaging in size a small bean. They had lasted for 25 years; some disappeared when fat in other parts of the body decreased. In 1887 Dr. W. K. Sibley⁶ exhibited a case of a man, aged 32 years, who for five years had symmetrical lipomata appearing on the body. He was a plethoric individual whose face showed capillary dilatation; and he was addicted to drinking beer and spirits. When he was working hard the swellings became reduced in size. In 1886 Mr. Morrant Baker and Mr. A. A. Bowlby⁷ described a large number of cases with multiple diffuse lipomata in which the individual swellings were from five to six inches long, softer and more deeply situated than in Mr. Gay's case, and of indefinite outline. They referred at the same time to previously recorded cases and drew attention to the fact that the patients were males and that in almost every case there was a history of hard drinking of beer and spirits. A few cases had derived slight benefit from the administration of liquor potassæ 20 minims three times a day (Brodie's⁸ method). No good had resulted in cases treated with tincture of iodine internally. In Quain's "Dictionary of Medicine" (third edition) the following interesting remarks occur in the

paragraph dealing with the treatment of lipomata: "Though fatty tumours are said to shift their position, and sometimes to diminish in size spontaneously, they are not to be dispersed by internal remedies or external applications. It is said that if they result from beer-drinking they will diminish if the habit be discontinued."

Remarks.—The case is of interest both from the pathological and the therapeutical point of view. The pathological interest lies in the association of fatty deposits and telangiectases and the possible relationship between these two phenomena. As the patient was unaware of the thoracic telangiectases and mottling of the skin it is impossible to say whether they preceded or followed the lipomata. The long history of white and numb fingers and ears points to the presence of a defective circulation existing for many years. In such subjects beer and spirits, being vascular dilators, are very injurious and tend to increase the unhealthy condition of the peripheral circulation. It has long been recognised that obesity is associated with defective circulation and it has been considered that the phenomenon is due to the resulting defective oxygenation of the tissues. Thus, obesity occurs with anæmia and with cardiac disease in certain persons. It is quite probable that the local fat deposits in the above case were due to a local stagnation of the circulation. Obesity in certain regions has been reduced by massage and irritants applied to the overlying skin, the reduction probably being due to the increased blood-supply to the part. It was, with this idea in mind that I commenced treatment with a strong caustic application over the tumours. As I did not expect the result which has fortunately occurred, the notes of the precise measurements, sites, and rapidity of diminution of the lipomata are not so accurate as they would otherwise have been. The treatment was pushed in the early stage till a dermatitis was excited; and the diminution of the tumours was very rapid during the first two months, more rapid than during the later stages, when dermatitis was avoided. In the spring of 1906 the patient observed that the lipomata had not made much improvement during the previous half year; and therefore the caustic applications were discontinued. The remaining portions of the lipomata (with the one exception above referred to) were at that time so deeply situated that it was improbable that cutaneous applications could affect them.

This method of treatment by caustics may be recommended where operation is inadmissible, by reason of the large number of the tumours, objection on the part of the patient, or for any other cause. In cases where it is desirable to avoid the scarring consequent on excision, this method may also be recommended because if carefully performed under medical supervision no scar need result.

Upper Berkeley-street, W.

THE TEACHING OF THE HYGIENE OF THE EXPECTANT AND SUCKLING MOTHER.¹

BY JOHN F. J. SYKES, M.D., D.Sc. EDIN.,
MEDICAL OFFICER OF HEALTH OF ST. PANCRAZ.

[Dr. Sykes commenced his paper by saying that in times past various factors had been assigned as the causes of a high infantile mortality. It now, however, seemed clear that faulty maternal hygiene was the *fons et origo mali*. The resisting powers of the infant by which it is enabled to fight adverse influences should be acquired and maintained for the nine months before birth just as much as during the nine months after birth. Therefore the hygiene of the expectant mother takes first rank and this, with the hygiene of the suckling mother, precedes all other considerations. Dr. Sykes then quoted certain statistics as to decrease in birth-rate, increase in the mortality of infants under one year, and decrease of breast-feeding. He continued:—]

Infantile mortality, from the point of view of deficient nutrition and viability, may be expressed in the following form:—

A. Ante-partum and ante-natal causes.—(a) As to the mother, resulting in (1) diminished vigour and reduced resistance to adverse influences; or (2) deficient nutrition, growth, and differential development of the embryo. (b)

the infant, resulting in (1) premature birth and death or later after birth; or (2) deficient viability and death or feeble early existence.

Post-partum and post-natal causes.—(a) As to the infant, resulting in (1) deficiency in quality or quantity of breast-milk; or (2) suppression of breast-milk through illness or designedly. (b) As to the infant, resulting in (1) excessive wasting; or (2) premature weaning and failure of the alimentary system. Initial low viability and consequent want of breast-milk are the main ultimate causes of the bulk of infantile mortality.

Dr. Sykes then quoted statistics from St. Pancras, Birmingham, Huddersfield, and Brighton showing how far infantile mortality is in the hand-fed than in the breast-fed infant. He continued:—]

Ante-partum and ante-natal conditions there are certain; they are moral and economic. The vices of alcoholism, the uses of certain drugs, and the incidence of certain diseases must be overcome by the moralist, but they are less largely than the great economic condition of poverty, which brings to the mother insufficient food, inefficient rest, excessive work, and extra stimulation, a vicious circle from which she can only be freed by the hand or the philanthropist. Work is not injurious to the expectant woman provided it be not heavy or prolonged. At the same expenditure of money the food and drink may be nutritious or valueless, and even injurious, according to the knowledge and inclination of the mother. It is here that medical advice becomes of so much value in directing the mode of life and the diet with a view of maintaining the health of the mother during some nine months' expectancy, and preparing her for suckling during another nine or ten months. It is here, too, that the father has his part to play in helping to provide the necessary food and rest. When we speak to the mothers of the country what shall we say to the fathers?

"The woman's cause is man's. They rise or sink together. Dwarf'd or godlike, bond or free; If she be small, slight-natured, miserable, How shall men grow?"

Assuming ante-partum conditions to have remained the same, we should have expected the mortality of infants under one year to have decreased *pari passu* with the death-rate at all ages under the influence of improved housing, greater cleanliness of the dwelling, diminished overcrowding, increased scavenging, extended sewerage, better removal and disposal of domestic refuse, and more perfect drainage, but these have been counteracted by increased hand-feeding, earlier weaning, diminished opportunity for continued breast-feeding due to the separation of the mother and the suckling for various reasons, diminished capacity to continue or even to commence breast-feeding due to the lowered health of the mother during the suckling period, or even earlier during the expectant period without later recuperation.

In regard to the feeding of suckling infants, the first thing is to reduce hand-feeding to the smallest proportion possible; it will then be an easier matter to deal with the few remaining hand-fed sucklings. In order to do this it is necessary to ascertain the causes of premature weaning and to remove them or to counteract them. In St. Pancras in 1904 it was ascertained that only about 60 per cent. of infants were wholly breast-fed; in 1905 the proportion had risen to 68·8 per cent. The actual numbers in each year were 457 breast-fed of 772 cases inquired into during 1904 and 530 of 793 cases in 1905. In 1905 fuller inquiry was made into 277 cases of prematurely weaned infants and the ages and causes of weaning were ascertained. In 71 cases there was only partial weaning. Of the 206 cases in which there was premature complete weaning it was found that 78 were weaned at birth, 73 within the first month, and 55 subsequently (mostly during the second and third month). Of these cases prematurely weaned, it was found that from one-half to two-thirds were probably preventable. Now, if of the 33·2 per cent. of sucklings not wholly breast-fed in 1905, one-half can be prevented, it follows that 63·4 per cent. can be wholly breast-fed and, if two-thirds can be prevented, nearly 89 per cent. can be breast-fed. I believe that if proper and complete measures were seriously taken the proportion of partially and wholly hand-fed sucklings need not reach even 10 per cent. Baron Katschiro Takaki, Surgeon-General of the Imperial Japanese Navy, informed me that 99 per cent. of the infants in Japan were breast-fed.

The causes of premature weaning are mainly dependent

upon the mother and of those that are dependent upon the infant a number are probably the effects of ante-partum conditions. The maternal causes of premature weaning are numerous but there is a material difference between those that do not separate mothers and sucklings and those that do. The main causes which do not necessarily separate the mother from her babe are (1) purposeful weaning to avoid the irksomeness of suckling, this is mainly confined to the leisured class; (2) incidental weaning through insufficient knowledge, this is common amongst the working classes, as are also the following: (3) lowered health or vigour of the mother and deficiency of breast milk, mainly due to erroneous and incomplete hygiene, including improper and insufficient food; and (4) more serious ill-health due to various causes, some of which are also preventable.

The main cause which separates the mother from her suckling babe is "going out to work." In illegitimate cases the father shirks his duty and the law only compels him to contribute partially towards the support of the child and not at all towards the support of the mother during the period that she should be suckling her infant. This is a difficult social question, but it was a pleasure to read in the public press that in the case of *McLaglen v. McLaglen*, in the Divorce Court on April 24th last, Mr. Justice Bargrave Deane ordered a baby, who had been forcibly carried off by the father, to be returned to its natural food at its mother's breast. The natural right of the child prevailed over the common law right of the father.

In legitimate cases the mother goes out to work either (a) because of the father dying, deserting, or idling, or (b) because the father is out of work through economic causes. There is no doubt that in St. Pancras the number of suckling mothers who go out to work does not approach by far the number going daily from home to factory in some of our large manufacturing towns. It is in these towns that the separation of mother and suckling infant cries out loudly for prevention. The remedy I suggest is that infants of suckling age should not be admitted to municipal crèches and public nurseries, but that a manufacturer who elects to employ the labour of mothers with suckling infants on account of its cheapness should provide a cradle-room for the infants and give facilities to the mothers to suckle their infants at proper intervals. This would mean about a quarter of an hour in the middle of each of the forenoon and afternoon shifts. At present a premium is placed upon hand-feeding which is destroying the vitality of the coming generation.

The length of time during which women should cease industrial work before and after confinement is still a matter of dispute. Most mothers, if sufficiently nourished, can do ordinary work, but exhausting work dries up the breast milk, especially that of ill-nourished mothers. In a report towards the end of 1904, instead of weaning and artificially feeding infants on modified milk, I advocated supplementing the mothers' diet, and, in a further report, recommended as the only method of humanising cows' milk—passing it through the mother. Madame Coulet, under the inspiration of Professor Coulet of Caen, was at that time (unknown to me) commencing to put into practical effect in Paris the feeding of necessitous suckling mothers, now carried on at a number of free restaurants, the only qualifications for admission to which are poverty and breast-feeding. Why can this not be carried out in England? guarded from abuse by the certificate of the woman inspector or voluntary visitor as to poverty, and by medical certificate as to health and breast-feeding?

There are numerous cases of malnutrition amongst our poor in which, on quitting the lying-in room, the breast milk dwindles or becomes impoverished. Many cases are known to nurses, midwives, and medical men and if reported and assisted the breast milk might be saved and enriched.

"The very first of human life must spring from woman's breast."

In the hygiene of the expectant and suckling mother is contained the most powerful preventive of infantile mortality. The teaching of the hygiene of the expectant and suckling mother has been said to be ideal. All work must be directed towards an ideal; the important question is whether the ideal is good, better, or best, and whether in adopting a good ideal as a temporising measure instead of a better you may not mar the best.

* Mrs. W. E. Gordon has started cheap dinners in Chelsea for nursing mothers insufficiently nourished. Thus both mother and infant are nourished at less cost than a hand-fed infant.

If hand-feeding is encouraged breast-feeding will be discouraged, if breast-feeding is discouraged the incentive to maintain the health of the suckling mother will no longer remain; and if the prospect of suckling be removed the preparation of the expectant condition of the mother will be neglected, not only with disastrous results to the suckling of the infant, but also to the building up of its constitution before birth. It is dangerous to arrest a series of consequential natural events in any part of their course. It has also been said that preventive medicine tends towards the survival of the unfit. The cultivation of natural processes rather than unnatural must be regarded as tending towards producing the fittest.

Every effort should be exhausted upon improving the health of the mother before directing efforts solely to the infant. The hygiene of the expectant and suckling mother cannot be taught to children in school, the wives and mothers themselves must be taught. Medical men, midwives, and maternity nurses must learn and must teach. Women inspectors and lady visitors must not only teach and influence mothers as soon as possible after the birth of infants but must make every effort to reach them before. There should be no divorce of advice as to the mother from advice as to the infant that should be dependent upon her for well-being and nourishment. When such a divorce takes place the principal error is already committed.

For a long time past it has struck me that the promiscuous distribution of leaflets instructing mothers how to hand-feed their infants is beginning at the wrong end, and even prefixing a few words of advice as to breast-feeding does not correct the preponderant details of advice as to how to avoid breast-feeding. In my opinion advice upon the cultivation of breast-feeding should be altogether severed from advice upon hand-feeding, and no leaflet of advice upon hand-feeding should be distributed promiscuously, but each such leaflet should be given only in each individual case to which it is applicable and only after all efforts to establish or to maintain breast-feeding have been exhausted and the medical adviser has definitely advised weaning, and the leaflet itself should bear the name and address of the particular mother's child to whom it is intended solely to apply. As to whether separate leaflets should be issued for the expectant and for the suckling mother may be a matter of opinion, and perhaps the preponderance is in favour of a combination, since from conception to weaning the infant is dependent for well-being and nutrition upon the mother for 18 months.

It is contrary to physiological law to expect that a mother can with impunity suppress or neglect the natural function of such large and active organs as the mammary glands. There are certain bad effects upon the health of the mother which we know may follow the neglect of the function of suckling, certain others that are surmised, and probably certain others of which we are ignorant, observation or research not having yet traced them to their true causes. We know that mammary abscesses may arise from this cause, and we also know that incomplete involution of the uterus follows from inactivity of the breast functions. It has been surmised that amongst the excitants determining the localisation of cancer the suppression of breast milk is to be reckoned. When it is realised that the breasts yield from one pint increasing to three or four pints of milk daily it can be readily realised what a profound influence the suppression of this natural process must have upon the physical and mental condition of the mother.

[Dr. Sykes here quoted the Card of Advice to Mothers which was issued by the St. Pancras Borough Council in 1905.]

St. Pancras has been fortunate in having two women inspectors, B.A.'s of London, holding certificates, and thoroughly conversant with their work, in which they are enthusiastic. This work, which Miss Bibby commenced, has been continued and elaborated by Miss Gardiner, since assisted by a staff of visiting ladies. The experience is: 1. That working-class mothers are specially anxious that their infants should be born healthy and robust and be healthily bred, and that they will make every effort and sacrifice to secure these results and welcome any advice and assistance to improve their own health and that of their sucklings. 2. That it is due mainly to want of knowledge, advice, and assistance that (a) a large number of infants are born prematurely and die soon after birth; (b) that a large number of full-time infants are born so feeble as to live only

a few weeks; (c) that a large number of infants are not suckled at the breast after being born; and (d) that a large number of infants who are suckled at the breast for a few weeks are weaned prematurely. 3. That by means of proper advice and assistance the health of expectant mothers can be improved and prepared for suckling and that of suckling mothers maintained; that the number of breast-fed infants can be largely increased; and that, as the mortality of breast-fed sucklings is so much less than that of hand-fed, the results of such action should be most beneficial. 4. That sick and weakly mothers, and consequently hand-fed sucklings, are special objects for medical supervision and guidance, each individual case requiring individual attention.

St. Pancras has also been fortunate in having as chairman of the public health committee Dr. R. M. Beaton, L.C.O., who convened the conference on the Prevention of Infantile Mortality, over which he presided in June, 1905, at the town hall, and which Sir William Broadbent, Sir Lauder Brunton, Mr. E. B. P. Moon, M.P., Professor Herbert Spencer, Mrs. Soharlieb, Miss Vaughan, Mrs. Fleming, and many other well-known persons supported. This conference, assisted by the women inspectors and a staff of lady voluntary visitors, gave an immense impetus to the movement and the elaboration of an organisation.

[Dr. Sykes then described the system of organisation which was elaborated at the above-mentioned conference. It included measures for obtaining information of births at the earliest possible moment and of information of expectant mothers. With regard to the giving of information, measures were adopted for advising mothers, both before the birth of their children and after, as to the best means of maintaining their own health and that of their children. Dr. Sykes continued:—]

Professor Pinard and Dr. Variot have called attention to the success of puericulture, both before and after birth, at Creusot, where the immense manufacturing works of Messrs. Schneider are situated. Messrs. Schneider have proceeded by encouraging municipal, and especially working-class, sanitation, by raising the salaries of workwomen so as to enable them to perform their functions of maternity, and by providing medical assistance to attend upon and advise the workpeople. Expectant mothers are properly advised as to hygienic measures; they are forbidden to work after the quickening, about the fifth month, or to return to work after convalescence until medically certified. The results have been a reduction in premature births, a reduction in infant mortality, and an increase of breast-feeding to over 80 per cent. The mayor, Mr. Benjamin Broadbent, in an open letter addressed to the mothers of Huddersfield, has described the success of his experiment, commenced in November, 1904, of offering £1 reward to every baby surviving the first anniversary of its birth in the township of Longwood. He has also described the series of regulations promulgated in 1894 by the mayor of Villiers-le-Duc in France for providing early and free medical advice and attendance for the expectant mother and subsequently for the suckling mother and her infant, together with a grant for extra food during the lying-in and the suckling period, and it is interesting to note in the recommendations supplementing the regulations how the mother is repeatedly advised to consult the medical man when any deviation from health occurs in any individual case.

These methods are on right lines. There is room for municipal effort in teaching and promoting the personal hygiene of mothers in association with the medical and nursing professions and the labours of sociologists and philanthropists, and (1) to teach mothers how to prepare for and maintain breast-feeding and not to wean prematurely; (2) to assist ill-fed mothers in obtaining proper nourishment to prepare for and maintain breast-feeding, utilising existing institutions, societies, and associations; (3) to advise mothers that if they must go out to work they must take their babies with them to continue breast-feeding; (4) to persuade employers to provide cradle-rooms and facilities to enable the suckling mothers employed to continue breast-feeding; and (5) to refer to medical attendants to advise those mothers who require special treatment to improve and maintain their health that they may order such necessities for mother or suckling as may be required.

With regard to untimely, heavy, or prolonged work by pregnant and suckling women in factories, workshops, and workplaces, it is provided in Part. IV. of the Factory and

Workshop Act, 1901, s. 79, "Where the Secretary of State is satisfied that any manufacture, machinery, plant, process, or description of manual labour used in factories or workshops is dangerous or injurious to health or dangerous to life and limb, either generally or in the case of women, children, and other class of persons, he may certify that manufacture, machinery, plant, process, or description of manual labour to be dangerous; and thereupon the Secretary of State may, subject to the provisions of this Act, make such regulations as appear to him to be reasonably practicable and to meet the necessity of the case"; and in s. 83 the regulations may, among other things—"(*a*) prohibit the employment of, or modify or limit the period of employment of, all persons or any class of persons in any manufacture, machinery, plant, process, or description of manual labour certified to be dangerous."

By s. 61 it is already provided that "an occupier of a factory or workshop shall not knowingly allow a woman or girl to be employed therein within four weeks after she has given birth to a child." If, therefore, the Home Secretary could prohibit, or modify or limit the period of, the employment in certain industries or processes of pregnant women after quickening, more good would be done than by the indiscriminate prohibition of pregnant women to work for a fixed period after confinement. If the Home Secretary cannot take action under existing provisions he should be given the power to make regulations for mothers during the expectant and suckling period as to the kind and amount of work they should be limited to in certain industries or processes after the quickening, and as to requiring employers to provide facilities for mothers to suckle their infants at intervals when at work during the suckling period.

In conclusion, it must be said that you cannot rear an imperial race on the bottle. History tells us through the ages that it was the mothers who reared the imperial races of the past, as they will continue to do in the future. If we intend to remain an imperial race, we must restore to its imperial place the dignity of motherhood, and repeat again and again: "The hand that rocks the cradle rules the world."

Camden square, N.W.

Medical Societies.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

Co-existence of Appendicitis and Obstruction.—Dislocations and Fractures of the Thumb and Great Toe.—Volvulus of the Entire Small Intestine, Cæcum, and Ascending Colon.

A MEETING of this society was held on March 26th, Mr. J. WARRINGTON HAWARD, the President, being in the chair.

Mr. J. HUTCHINSON, jun., gave an account of a case of Co-existence of Suppurative Appendicitis and Intestinal Obstruction in a girl, aged 15 years. The girl had suffered from an attack of appendicitis some months previous to the onset of acute symptoms. The abdomen was opened in the middle line, the obstruction relieved, and the feetid pus removed from the abdomen. The girl made a good recovery.

Mr. HUTCHINSON also showed a series of drawings and radiographs illustrating certain Dislocations and Fractures of the Thumb and Big Toe.

Mr. HUTCHINSON then read an account of Volvulus of the Entire Small Intestine, Cæcum, and Ascending Colon. He said the anatomical condition which led to complete volvulus was due to a defect in development. The arrest of development being congenital complete volvulus was most common in children and much more frequent in males than in females. The whole of the intestine supplied by the superior mesenteric artery, from the duodenum to the transverse colon, underwent torsion to the amount sometimes of 360°. In nine out of the ten cases reviewed and abstracted in the paper this rotation brought the cæcum and ascending colon behind the mesentery, which latter acted as an obstructing band. In one case the rotation was in the opposite direction. The cæcum, greatly distended, might be found close to the spleen or in the left iliac fossa. The condition was very difficult to recognise even after the

abdomen was opened and there seemed to be only two successful cases of operation on it recorded. The first was Mr. Hutchinson's, operated on in 1901; and the second was operated on by Brentano in 1904. It was essential to draw the intestines outside the abdomen in order to recognise and to reduce this form of volvulus and it was advisable to evacuate the cæcum by tapping.—Mr. A. E. BARKER mentioned a case of volvulus of the whole of the small intestine, but not of the cæcum. The case was that of a woman on whom he had performed a gastro-enterostomy some two years previously for hæmatemesis. She married and became pregnant and was suddenly taken ill with pain in the abdomen and vomiting. The abdomen was opened and the volvulus recognised; this was reduced without taking the intestine out of the abdomen. The ease with which the intestine could be rotated within the abdomen was surprising. He considered it unnecessary in most cases to remove the intestine from the abdomen in order to reduce the volvulus.—Dr. ARTHUR KEITH said that the assumption of the upright position in man necessitated the fixation of the intestine in a manner different from that which was seen in the lower animals. In all the anthropoid apes he had found that the intestines were fixed in the same way as in man. The type of intestine and fixation which was found in Mr. Hutchinson's case corresponded to the form which was found in the lower animals. He had found a volvulus similar to that described by Mr. Hutchinson in a child who was born dead and that was due to a defective development—the attachment of the intestines.—Mr. GERALD S. HUGHES gave an account of a similar case in which a woman who all her life had been subject to attacks of abdominal pain suddenly developed signs of acute obstruction. She only came under observation half an hour before death and at the necropsy the whole of the small intestine was found twisted on itself; the cæcum was, however, in the normal situation.—Mr. HUTCHINSON, in reply, said that neither the case recorded by Mr. Barker nor that recorded by Mr. Hughes corresponded to those which he had described. The cases which he described formed a distinct group dependent on a congenital deformity. He could not agree with Mr. Barker that it was inadvisable in these cases to remove the intestine from the abdomen. He felt sure that the failure to cure the patients in some cases was due to the fact that the intestine had not been removed and the condition not relieved owing to it not being recognised.

LEEDS AND WEST RIDING MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on March 22nd, Dr. A. H. Bampton being in the chair.—Dr. J. B. Hellier read a paper on Post-operative Pneumonia and Bronchitis, in which he said that, though estimates of the frequency of such complications varied greatly, their occurrence was well recognised, some continental authorities finding 4 or 5 per cent. of pneumonia in abdominal cases after operation. The factors in causation were multiple. Dr. Hellier discussed the parts played respectively by the condition of the patient, chilling of the patient in the wards, corridors, and theatre, infection by the inhaler, septic state of the mouth and teeth, aspiration into the lungs, specific action of ether on the lungs, purity of the anæsthetic, faults in administration, and so on. He then considered in detail the various precautions which such a review of causation suggested, such as preparation in the ward, precautions during operation, methods of administration, and after-treatment.—A suggestive discussion followed.—Dr. A. Bronner read a paper on the Surgical Treatment of Diseases of the Nasal Accessory Cavities. He drew attention to the fact that these diseased cavities were a very common cause of anæmia, gastritis, meningitis, atrophy of the optic nerve, and disease of the cavernous sinus. The maxillary antrum was affected most frequently and the disease could spread from there into the frontal and ethmoidal cells. He generally opened up the antrum through the alveolar process and inserted a large Williams tube. The cavity should be washed out daily, powders insufflated, and if there was any discharge after two or three months the antrum should be plugged with ribbon gauze, through the tube. This method often effected a cure in the most tedious cases. In very bad cases the radical operation should be performed through the canine fossa and a large opening made into the nares. In disease of the maxillary antrum there was often pain over the frontal sinus and the antrum should always be explored before the sinus was opened.

For disease of the frontal sinus Killian's operation was the best in severe cases. This and other methods were described. The anterior ethmoidal cells were very often diseased and were the cause of the frequent recurrence of nasal polypi; the best method was to remove them with Meyer's ring. Disease of the posterior ethmoidal cells and the sphenoidal sinus often gave rise to meningitis, atrophy of the optic nerve, paralysis of the ocular muscles, and disease of the cavernous sinus. These cases were very frequent and generally overlooked. The use of adrenalin had greatly simplified these operations.—The following among other cases and specimens were shown:—Professor A. S. F. Grünbaum: A Fibrotic Testis and the Brain showing Minute Hemorrhages from a Syphilitic Chimpanzee.—Dr. F. W. Earich: Meningeal Hemorrhage in a case of Anthrax.—Mr. James Ewing: A patient suffering from "Hairy" Black Tongue. There was great elongation of the filiform papillae in the centre of the dorsum and they looked like black hairs.—Mr. B. G. A. Moynihan: (1) Carcinoma of the Jejunum; and (2) a patient upon whom Transplantation of an Extroverted Bladder was performed.—Mr. J. T. Fox: Specimens from Acute Fatal Congestion of the Pancreas, Suprenals, and Duodenum.—Dr. A. L. Whitehead: Specimen of Multiple Cysts of the Retina causing Absolute Glaucoma.—Mr. R. L. Knagge: Specimen showing Ureters implanted into the Rectum from an infant one year old. Death took place from causes unconnected with the operation some time afterwards.—Dr. W. H. Maxwell Telling: A case of Chronic Lichen Planus of 11 years' duration with recent exacerbation.

DERMATOLOGICAL SOCIETY OF GREAT BRITAIN AND IRELAND.—A meeting of this society was held on March 27th, Dr. Alfred Eddowes, a Vice-President, being in the chair.—Mr. Arthur Shillitoe showed a case of Untreated Syphilis in a man, aged 22 years, the primary infection being in September, 1906. The trunk, limbs, and scalp presented a very extensive scaly and crusted eruption which in parts was psoriasisform in character. The fauces were much ulcerated.—Dr. Eddowes showed: 1. A man, aged 37 years, with Scarlatinoid Exfoliative Erythema. The patient had had two previous attacks and at the present time there was marked desquamation of the soles of the feet. His general health was unaffected. 2. Two sisters: one, aged 29 years, with Tylosis Palmæ, of hereditary origin, the mother and eldest brother being also affected in a similar manner; the other, aged 27 years, with Palmar Warts. 3. A boy, aged 15 years, with Pelliosis Rheumatica.—Mr. Spencer Harbutt exhibited: 1. Two men, one, aged 45 years, with a Guttate Psoriasisform Eruption scattered nearly all over the body, face, and scalp of 14 days' duration, with a more or less greasy, fawn-coloured eruption over the sternal region; the other, aged 23 years, with a somewhat similar rash but with no sternal eruption. (A lively discussion took place with regard to the exact nomenclature of these two cases and to the relationships between seborrhoea corporis and psoriasis.) 2. A young woman, aged 24 years, with Bazin's Disease, affecting the usual region of the middle third of the legs, but in whom there were also infiltrated nodules upon the extensor aspect of the forearms. The condition began on the left arm a year ago.

NOTTINGHAM MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on March 20th, Mr. E. Powell, the President, being in the chair.—Mr. J. Mackie showed a boy, aged 15 years, who for eight years had suffered from Chronic Suppurative Otitis Media. There had been occasional attacks of pain for the last two years accompanied by vomiting and giddiness, usually followed and relieved by profuse discharge of pus. The temperature ranged from 97° to 105° F. and thrombosis of the lateral sinus was diagnosed. On Sept. 27th, 1906, the mastoid antrum was opened and found to be continuous with an extradural abscess. The sinus was opened, the clot removed, and the abscess drained. Four days after the operation the patient developed left basal pneumonia and pericarditis with daily rigors. Nine days after the operation the temperature fell from 106·2° to 95° in three hours. Four days later a profuse expectoration of foul purulent material occurred, probably from a pulmonary abscess. Nine days later (Oct. 19th) a swelling developed in the neck along the course of the internal jugular vein. The neck was freely incised and the abscess was opened after tying the internal jugular vein at its junction with the subclavian. The boy

made an uninterrupted recovery and is now in excellent health.—Mr. R. C. Obicken read a paper on Renal Calculus, in which he analysed critically, from the point of view of diagnosis, all the symptoms in ten recent cases. The three cardinal symptoms of hæmaturia, local tenderness, and renal pain were variable within such wide limits that corroborative evidence, such as was sometimes obtainable by the x rays, was often extremely valuable. Pain might radiate as far as the breast, the scapula, or the iliac crest; while, on the other hand, pain and tenderness might be completely absent. In one case renal calculus was complicated by suppurative appendicitis and in another by pain over the gall-bladder, jaundice, and wasting. In a third the tumour was formed by a large pyonephrosis, below which a large stone was found. In one typical case no stone could be found by nephrotomy, and in another the pain was so slight that a large uric acid stone would probably not have been detected but for the help of x rays. Then, again, all the pain might be referred to the healthy side and much confusion might be caused when pain was set up by a long adherent, chronically inflamed appendix.—Dr. F. H. Jacob read a paper on the Use of the X Rays in the Diagnosis of Renal Calculus, in which he pointed out that with the improved coils now in use a better picture of the kidney and its relations could be obtained in difficult circumstances than formerly. The necessary time had also been greatly reduced and as the kidney moved on an average one and a half inches at each respiration, this had its importance. Scoliatic masses were much more obvious in an x-ray photograph than a calculus would be, and this fallacy had to be guarded against by complete evacuation of the bowels. Calcified tuberculous glands were another source of error.—Dr. Jacob also read a paper on two cases of Leucocythæmia treated by X Rays. Both patients showed marked improvement.

GLASGOW MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on March 15th, Dr. J. Lindsay Steven, the President, being in the chair.—Dr. A. A. Young showed a case in which ulcerative perforation of the stomach and two cases in which ulcerative perforation of the duodenum had been successfully operated on. The success of these cases was largely due to early treatment, the intervals between the first symptom and the operation being from four to seven hours. Dr. Young had operated on 11 such cases with six recoveries and five deaths. The diagnosis was generally made from sudden and violent pain, with rigidity and tenderness of the abdomen. The previous history was of little service, for there were many cases of perforation in which ulceration had not been suspected. The peritoneum should be gently sponged after the ulcer had been sewn up with as little handling as possible. The area of perforation should be drained and Fowler's position adopted as it lessened the danger to the lungs.—Dr. A. N. McLennan read a paper on Professor Bier's Treatment for Infective Lesions and showed some of the Bier-Klapp apparatus. It was suggested that the word "staunung" used by Professor Bier to denote the hyperæmia produced by the elastic band might be incorporated in the English vocabulary. The "staunungshyperæmie" of Bier was produced by applying a light Martin's indiarubber bandage as remote from the inflammatory region as convenient. The degree of tightness was important. The correct application ought not to produce pain but to relieve it. It intensified the signs of inflammation, such as the redness and the swelling. The bandage was retained in acute cases for 22 hours. An interval of from two to four hours was employed in reducing the œdema the result of the bandage. Where pus existed it must be given vent to, but small incisions were sufficient. During the treatment all dressings must be very loosely applied. The dangers attributed to the treatment, such, for instance, as increase of pain, extension or dissemination of the infection, erysipelas, and hemorrhage, were due to faulty technique, while the illness observable during the interval of the treatment was due to the absorption of endotoxins. The method was applicable to many septic conditions and was especially serviceable as a means of preventing wounds becoming septic. The treatment of localised inflammatory conditions by means of suction apparatus was most successful. The apparatus was allowed to act for five minutes, then there was a pause of three minutes; the alternation of suction and interval was repeated for about an hour daily. Tuberculous joints were treated by Professor Bier in a large apparatus producing a partial vacuum.

Operative Otolology, Surgical Pathology and Treatment of Diseases of the Ear. By CLARENCE JOHN BLAKE, M.D., Professor of Otolology in Harvard University; and HENRY OTTRIDGE REIK, M.D., Associate in Ophthalmology and Otolology, Johns Hopkins University. With 13 plates. London: Sidney Appleton. 1906. Pp. 359. Price 15s. net.

In the first chapter 37 pages are devoted to the surgical anatomy of the temporal bone and its surroundings, while the second chapter deals with antiseptic technique. The former is a clear and lucid description of the more important surgical anatomy. The form of sterilization of the instruments most recommended by the authors is that by means of formaldehyde gas; sterilisation by this method can be accomplished in a very short space of time and has the great advantage of not blunting sharp or dulling bright instruments. The remainder of the chapter calls for no particular remark but it is one which will be very useful for refreshing the memory of those who have forgotten the antiseptic technique. The third chapter—diseases of the auricle and external auditory canal—deals with malformations and ordinary diseases of these parts. In treating of the removal of exostoses of the canal the operation through the canal is recommended for those near the external surface and reflection of the auricle for pedunculated and deep-seated growths. On p. 86 an extremely neat little chisel is depicted, having a small metal handle fastened on to it obliquely a short distance from the proximal end of the shaft. In the fourth chapter, which deals with diseases of the tympanic membrane and tympanum, we notice that the inflammations of the tympanic membrane are treated separately from inflammation of the middle ear. We think that this is unwise, as, with the exception of cases in which inflammation of the tympanic membrane results from direct irritation from without, it can only occur in conjunction with inflammation of the middle ear. An extremely useful syringe of the Pravaz type is depicted, with a long straight metal nozzle, which is introduced through a small perforation in order thoroughly to wash out the tympanum itself; this must of necessity be of greater use in perforations of Shrapnell's membrane. When speaking of chronic suppuration, in view of the tendency that exists in this country to an early resort to operative measures, the following remarks of the authors are worthy of note: "Having patiently, persistently, and perseveringly tried all simple means of overcoming the otorrhoea without success, the existence of a deeper focus of suppuration in a bone necrosis is presumable." Further on in the same page we find: "Ossiculectomy is considered appropriate where ossicular ulceration is present, and the mastoid operation where extension of suppuration to the cellular structures of the mastoid is presumed." This is, we think, sound surgery.

The next chapter deals with the various complications following suppurative otitis media. It is an excellent chapter but contains no strikingly original remarks. The authors state that the most trustworthy statistics at the present time indicate that one case of intra-labyrinthine suppuration occurs in every 100 cases of purulent middle-ear disease. This is a useful statement and is probably based on a sufficient number of cases to prove its correctness. In exploratory tympanotomy a very clever idea is suggested for returning the flap to its normal situation, which is done by means of damping a small crescentic portion of highly glazed paper and causing it to adhere first to the flap and afterwards to the edge of the tympanic membrane. A similar procedure is advocated for the closing of old perforations and appears to us to be one which, if carefully

performed, may be extremely useful in selected cases. A good many of the terms used are distinctly Transatlantic. Thus "tympano-antral extirpation" is practically what is known as the Stäcke operation but is not very clearly described. The term "mastoidectomy" is employed for those operations in which the mastoid process is attacked, and "mastoido-tympanal extirpation" is, as we read it, the term employed for what is known by us as the complete mastoid or radical mastoid operation. The last chapter consists of an abstract from a paper written by Bourguet in 1905 and published in the *Annales des Maladies des Oreilles, du Nez et du Pharynx*.

This book is one which we can strongly recommend as an excellent guide to operative aural surgery, though as we have said the terms employed are not always those which we employ in England. This, however, does not seriously impair the usefulness of the volume.

A History of Chemistry. By F. P. ARMITAGE, M.A., F.C.S. London: Longmans, Green, and Co. 1906. Pp. 268. Price 6s.

THE history of chemistry tells the story, as the author owns, of some thousands of years of almost fruitless labour, followed by two centuries of richest accomplishment. It is now debatable which of these centuries has borne the greater fruit. Ten years ago, perhaps, there could have been no question but it is the last decade which has brought us face to face with the suggestion engendered by the study of radiant matter and radio-activity that we have actually touched the borderland where matter and force seem to merge into each other. The eighteenth century saw the atomic conception become a theory which was so strongly supported by well-ascertained facts as to bring it almost to the level of certainty but hardly had the century passed away when these views became modified by the wonderful glimpse which was gained into the nature of radio-active phenomena; that, after all, the atom was not a stable entity; that there were such things as a disintegrating atom and a non-disintegrating atom existing side by side in the same sphere; that, after all, the atom is a mass of electrons some of which may break away to form new groups, the electrons, in short, being units of electricity. Nowadays, therefore, no history of chemistry can be complete which does not regard this development and we are led to ask why Mr. Armitage chose to conclude his story abruptly with the account of the periodic functions of the elements. To do him credit, however, the narrative up to this point is well told and he must have taken great pains to collect the materials and to present the facts in their proper historic sequence. He commences with almost prehistoric times, when, chemical knowledge did not go further than the manufacture of such articles as glass and soap, and the isolation from their native ores of easily reducible metals such as gold, silver, lead, and copper. Classification was not attempted until Aristotle assumed the existence of four elements but crude as this was it stimulated inquiry and the notion of transmutation gained credence. Towards the middle of the seventeenth century the view of the existence of four elements had to be abandoned in the light of accumulating facts which were the outcome of a more or less systematic research. We now know how rapidly this knowledge advanced from the time that Paracelsus regarded chemistry as the handmaid of medicine, as the author puts it, down to the time of Boyle's work (1661), and then on to the labours of Stahl, Hoffmann, Black, Priestley, Cavendish, Scheele, Lavoisier, Dalton, Davy, Gay Lussac, Avogadro, Berzelius, Liebig, Gerhardt, Kekulé, and so on to near the end of the last century. Mr. Armitage recounts the history of all these men, their labours and their careers, in terms which cannot fail to interest the student who is desirous of knowing how the science of

chemistry was built up, and he is justified, we think, in venturing to hope that it will be the readers' fault if after applying common intelligence to the reading of this volume they fail to "see problems in a clearer light and attack them with minds broadened by contact with those of their famous predecessors." We trust in a future edition that the author will bring his literary power and scientific knowledge to bear upon recent advances, which means telling his readers how men came to think of electrons and of radiant matter and to revert to the old idea of transmutation.

Infant Education. By ERIC PRITCHARD, M.A., M.D. Oxon., M.R.C.P. Lond., Consulting Physician to the Barnet Home Hospital for Children, &c. With a Preface by ALEX. WYNTER BLYTH, M.R.C.S. Eng., Medical Officer of Health of the Borough of St. Marylebone. London: Henry Kimpton; Glasgow: A. Stenhouse. 1907. Pp. xiii.-190. Price 2s. net.

THIS meritorious little volume forms the first of the Borough of St. Marylebone Health Society's series and if the succeeding issues are as practical in character and interesting in style the whole should constitute a very useful and successful undertaking. Indeed, the existence of the Marylebone Health Society is a sign of the *Zeitgeist* and shows the increased attention now being paid to the physical side of social problems. Much has already been written on the alarming mortality which occurs among young infants and on methods of checking this waste of human material. This little book offers practical advice for home use which should arm the inexperienced mother against some of the more deadly errors sanctioned by evil customs and foolish traditions. The first chapter deals with the feeding of infants and shows that the digestive organs need education if they are duly to perform their functions in after-life. The importance of breast-feeding is duly enforced. In some cases, however, artificial feeding is inevitable. Emphasis is laid upon the need for proteid food and fats and for proper sterilisation of milk; for this last purpose boiling is commended as the most practicable. Milk so treated is held by the author to be more digestible, while any scorbutic tendency may be met by the addition of a little fresh fruit juice or meat juice to the dietary. The second chapter deals with antenatal hygiene or the mother's duty to the unborn child. Warnings are given not only against such poisons as alcohol and narcotic drugs but also against the evils of over-indulgence in rich food, against the possible effects of violent emotions, and against failure to take sufficient daily exercise. The author appears to attach more weight to maternal impressions as a source of fatal anomalies than is usually admitted. Chapter III. is devoted to the subject of habits, and stress is laid on the need for the cultivation of regular habits as to taking food, action of the bowels, and so forth, while careful education of the thermotactic mechanism is inculcated in order that a healthy tolerance of changing conditions may be obtained. The fourth and last chapter is devoted to examination of the infant in his home and contains advice to the health visitors as to the "points" of a baby and as to investigation of his condition and the state of his surroundings, especially the cot, feeding-bottle, and clothes. An appendix supplies further data for guidance in such examination and printed forms for recording the results obtained. Taken as a whole, this is an excellent little book for the purpose at which it aims. It is popular in style and evidently intended rather for the lay than for medical readers. Nevertheless, the newly qualified practitioner might benefit by its perusal, if only by being led to recognise the existence of numberless details of nursery hygiene upon which he may have to give an

LIBRARY TABLE.

The World's Classics.—Vol. lxxix., Sheridan's Plays, with an introduction by JOSEPH KNIGHT; vols. lxxxix. and xc., The Professor at the Breakfast Table and the Poet at the Breakfast Table, by OLIVER WENDELL HOLMES, with an introduction by W. ROBERTSON NICHOLL; vols. xci. and xcii., Pendennis, with an introduction by EDMUND GOSSE; vol. xciv., Scott's Lives of the Novelists, with an introduction by AUSTIN DOBSON; vol. xci., The Works of EDMUND BURKE (vol. iii.), with an introduction by FRANK H. WILLIS. Henry Frowde, Oxford University Press. Price 1s. per vol. net bound in cloth.—These seven volumes are a further instalment of the excellent series some former members of which were reviewed in our issue of Dec. 22nd, 1906. Three of them—namely, that by Sheridan and the two by Wendell Holmes—are known to everyone but we expect that few of the present generation have read either Scott's "Lives of the Novelists" or any speech of Burke. As regards Sheridan, Mr. Knight tells the reader in his introduction all that he need know about that brilliant but erratic person. Of the novelists dealt with by Scott we should say that the names of Bage, Cumberland, and Reeve are unknown except to professed litterateurs nowadays, and to these names we may possibly add that of Mackenzie. Mr. Austin Dobson in his introduction recalls the fact that so long ago as 1826 a house party were "devouring" the Lives and were stimulated by their perusal to try to read "The Man of Feeling." No one, however, could do so. Of the two volumes by Holmes we need only say the sight of them makes us hope that a future number of the World's Classics will be "The Autocrat at the Breakfast Table." Mr. Gosse, in his introduction to "Pendennis," is not blind to the faults of the work, as no one can be who loves his Thackeray. But if there are faults let us remember the excellencies. How much poorer would English literature be without the gallery of Pendennis portraits. That of the never-to-be-forgotten author of "Mes Larmes" would alone atone for pages of dullness. The volume devoted to Burke contains speeches made between 1771 and 1792, and the first one given is the magnificent speech which he made on the hustings at Bristol previously to the election in 1780. We look with interest to further instalments of the World's Classics.

The Public Schools Year Book for 1907. London: Swan Sonnenschein and Co. Pp. 533. Price 3s. 6d. net.—This, the eighteenth issue of this useful annual, contains particulars of all public schools connected with the headmasters' conference, together "with a few carefully weighed and necessary exceptions." It contains a variety of educational information which should be found indispensable by nearly all parents or guardians.

The Schoolmaster's Year Book and Directory, 1907. London: Swan Sonnenschein and Co. 1907. Pp. 574. Price 6s. net.—This annual publication is to the teaching profession much what the Medical Directory is to the medical profession. A consideration of this work and of the one previously noticed rather leads the reader to the conclusion that there is in this country too much teaching and too little learning, for the practical results seem by no means commensurate with the money and the brains which are spent upon teaching, or rather, we should say, upon education, two terms which are by no means synonymous.

Atlas of Cutaneous Morbid Histology. Consisting of 55 coloured figures on 24 plates and text. By MAX JOSEPH, Physician for Skin Diseases in Berlin; and J. B. VAN DEVENTER, Oberstabsarzt (Surgeon-Major) of the Netherlands East Indian Army in Batavia, Java. London: Archibald Constable and Co., Limited. 1906. Price 12s. net.—The names of the authors are sufficient to guarantee that the work before us has been prepared with great care and a

close examination of the volume confirms this expectation. The plates are excellent, wisely chosen, and clearly printed; they are not all, perhaps, of equal merit but not one is poor. The elucidatory text is reasonable in extent and fairly represents current views. The nomenclature of skin diseases has always proved a difficult matter and in a few instances it might have been well to assimilate the nomenclature to that common in this country. It is a pity, for instance, to speak of a primary syphilitic sore simply as "ulcus durum." Dr. Max Joseph is responsible for the text and the choice of specimens, while the credit of the illustrations is to be assigned to Surgeon-Major van Dantver.

JOURNALS AND MAGAZINES.

Journal of Anatomy and Physiology. Conducted by Sir WILLIAM TURNER, K.C.B., F.R.S., D. J. CUNNINGHAM, F.R.S., G. S. HUNTINGTON, M.D., A. MACALISTER, F.R.S., and J. G. MCKENDRICK, F.R.S. Vol. XLII. Series III. Vol. II., Part 2. With plates and illustrations in the text. London: Charles Griffin and Co. 1907. Subscription for four parts, 21s.—This part contains: 1. The Mechanical Supports of the Pelvic Viscera, by Professor A. Melville Paterson, M.D. Edin. The account of the fasciæ, ligaments, and sheaths of muscles here given is not only derived from careful dissection of the human subject but includes dissection of several mammals, as the kangaroo, horse, porcupine, Persian goat, and duiker-bok, most of which are illustrated by drawings in the text. The dissections were undertaken to correct a serious misapprehension which pervades the description of the pelvic fasciæ in anatomical writings and partly also to give a rational explanation of the relations of the pelvic viscera to the pelvic floor. The author remarks that the surgeon is now dealing with this region in a way that is not compatible with the descriptions in anatomical text-books. "It is an example of practice outgrowing dogma." 2. Varying Positions of the Carpal Bones in the Different Movements at the Wrist, by Henry M. Johnston, M.B. R.U.I., with eight illustrations in the text. 3. Notes on Predynastic Egyptian Tibiæ, by Douglas E. Derry, M.B. Edin. The article is the result of the examination of a series of between 400 and 500 predynastic Egyptian tibiæ. 4. A Description of the Peritoneal Cavity founded on Clinical and Pathological Investigations, by G. J. Jenkins, M.D. Edin., and S. Maynard Smith, F.R.C.S. Eng., with four drawings in the text. 5. The Interpretation of the Primary and First Secondary Wave in Sphygmographic Tracings, by Thomas Lewis, D.Sc. Wales, M.B. Lond., with seven figures in the text. 6. Note on Accessory Coronary Arteries, by William St. Clair Symmers, M.B. Aberd. 7. Complete Bilateral Interruption of the Fissure of Rolando, by David Waterston, M.D. Edin., with three plates in the text. 8. Congenital Obliteration of a Portion of the Alimentary Canal, by David Waterston, M.D. Edin. 9. The Physiology of the Lateral Atlanto-axial Joints, by Edred M. Corner, F.R.C.S. Eng., B.Sc. Lond. 10. The Arrangement of the Synovial Membrane in the Palmar Digital Sheaths, by Charles R. Whittaker, L.R.C.P. Edin. The part contains the Proceedings of the Anatomical Society of Great Britain and Ireland for June, 1906. An index, which we have not received, is stated to be published with this part, including Vols. XXXI. to XXXIX.

Transactions of the American Ophthalmological Society; Forty-first Annual Meeting. Vol. X., Part 3. Hartford: Published by the Society. 1905. Pp. 242.—The forty-first annual meeting of this society was held in Boston, Massachusetts, and was attended by 80 of the 170 members constituting the society. 29 communications were presented, amongst which were the following. Two cases of Melanosarcoma of the Choroid, by Dr. Charles J. Kipp. Though almost confined to the globe, in one of these cases localised oedema of the eyeball occurred only at intervals of weeks.

There was much pain. The eye was removed and the tumour on examination proved to consist chiefly of pigmented polygonal cells and unpigmented spindle cells which had invaded all layers of the choroid and had perforated the sclera. In the other case the growth was only six millimetres in diameter and two millimetres in height and yet had invaded the sclera. Dr. G. F. Schweinitz and Dr. E. A. Shumway report two cases of Melanoma of the Choroid, which are interesting as showing that the starting point of the melanotic growths was observed to be in the layer of large vessels. Dr. C. W. Cutler communicated the details of a case of Metastatic Pigmented Carcinoma of the Ocular Body. Dr. Edgar S. Thomson exhibited a Sachs's Lamp which had been devised by Mr. Moyrowitz of New York and by means of which the recognition of exudates and of foreign bodies in the eye is facilitated. Dr. Sattler described various improvements in the methods of application of the electro-magnet. In the discussion that followed the reading of this paper considerable differences of opinion were expressed as to the relative advantages of the large and small magnet in the extrication of fragments of iron and in regard to the advisability of making an incision through the sclerotic to introduce the small magnet. The direct application of the large magnet appears sometimes to inflict severe injury to the eye, one speaker, Dr. J. E. Weeks, recording a case of the entire iris coming away with the foreign body on the application of the large magnet. Dr. William Sweet gave the results of his investigations on the magnetic properties of steel alloyed with nickel, manganese, chromium, and tungsten. Manganese steel is the only alloy which materially reduces the magnetic induction of steel. Dr. John L. Weeks contributed a good article on the Various Methods employed for Localising Foreign Bodies in the Eye by Means of the Roentgen Rays. Dr. Lucien Howe read a paper in which, as the result of numerous inquiries addressed by him to the members of the society, he said that he was unable to obtain evidence of the numerous reflexes which by some practitioners have been held to be due to eye-strain. Dr. Hiram Woods gave an account of the conclusions at which he arrived from the study of Nine Cases of Recurrent Iritis. In a case which he saw with Dr. Knapp the substitution of a 10 per cent. solution of euphthalmine for atropine proved very serviceable. Dr. Hansell described a case of Cystic Myxo-sarcoma of the Orbit the excision of which was followed by death. Dr. Charles S. Bail discussed in his communication the Treatment of Inoperable Cases of Malignant Disease of the Orbit by the X Rays. Occasionally success appears to attend this method of treatment but the general results are disappointing. Vernal Conjunctivitis in the Negro was the subject of a paper by Dr. Dunbar Roy. The effects of high-frequency currents in certain ocular affections were treated by Dr. John O. Lester. Affections of the Cornea were considered by Dr. J. Morrison Ray, by Dr. J. Herbert Claiborne, and by Dr. F. O. Wadsworth. Dr. Claiborne also described a case of Homonymous, Left-sided Inferior Hemianopsia following a toxic dose of salicylate of sodium. Dr. Wilbur Marple described a case of Persistent Pupillary Membrane. Dr. Charles Williams exhibited a series of Reversible Test Types and Dr. John Green presented some notes on the Clinical Determination of the Acuteness of Vision. Dr. W. O. Posey contributed the details of a case of Cyanosis Retinæ occurring in a Cyanotic Patient. Lastly, a valuable paper was read from the pen of Dr. A. Duane upon the Symptoms presented by the Different Bacteriological Types of Acute Conjunctivitis. From Dr. Duane's observations it appears that no particular type of conjunctivitis is to be associated with a particular germ and that from the clinical aspect of a conjunctivitis no positive inference can be drawn as to the germ causing it.

chemistry was built up, and he is justified, we think, in venturing to hope that it will be the readers' fault if after applying common intelligence to the reading of this volume they fail to "see problems in a clearer light and attack them with minds broadened by contact with those of their famous predecessors." We trust in a future edition that the author will bring his literary power and scientific knowledge to bear upon recent advances, which means telling his readers how men came to think of electrons and of radiant matter and to revert to the old idea of transmutation.

Infant Education. By ERIC PRITCHARD, M.A., M.D. Oxon., M.R.C.P. Lond., Consulting Physician to the Barnet Home Hospital for Children, &c. With a Preface by ALEX. WYNTER BLYTH, M.R.O.S. Eng., Medical Officer of Health of the Borough of St. Marylebone. London: Henry Kimpton; Glasgow: A. Stenhouse. 1907. Pp. xiii.-190. Price 2s. net.

THIS meritorious little volume forms the first of the Borough of St. Marylebone Health Society's series and if the succeeding issues are as practical in character and interesting in style the whole should constitute a very useful and successful undertaking. Indeed, the existence of the Marylebone Health Society is a sign of the *Zeitgeist* and shows the increased attention now being paid to the physical side of social problems. Much has already been written on the alarming mortality which occurs among young infants and on methods of checking this waste of human material. This little book offers practical advice for home use which should arm the inexperienced mother against some of the more deadly errors sanctioned by evil customs and foolish traditions. The first chapter deals with the feeding of infants and shows that the digestive organs need education if they are duly to perform their functions in after-life. The importance of breast-feeding is duly enforced. In some cases, however, artificial feeding is inevitable. Emphasis is laid upon the need for proteid food and fats and for proper sterilisation of milk; for this last purpose boiling is commended as the most practicable. Milk so treated is held by the author to be more digestible, while any scorbutic tendency may be met by the addition of a little fresh fruit juice or meat juice to the dietary. The second chapter deals with antenatal hygiene or the mother's duty to the unborn child. Warnings are given not only against such poisons as alcohol and narcotic drugs but also against the evils of over-indulgence in rich food, against the possible effects of violent emotions, and against failure to take sufficient daily exercise. The author appears to attach more weight to maternal impressions as a source of foetal anomalies than is usually admitted. Chapter III. is devoted to the subject of habits, and stress is laid on the need for the cultivation of regular habits as to taking food, action of the bowels, and so forth, while careful education of the thermotactic mechanism is inculcated in order that a healthy tolerance of changing conditions may be obtained. The fourth and last chapter is devoted to examination of the infant in his home and contains advice to the health visitors as to the "points" of a baby and as to investigation of his condition and the state of his surroundings, especially the cot, feeding-bottle, and clothes. An appendix supplies further data for guidance in such examination and printed forms for recording the results obtained. Taken as a whole, this is an excellent little book for the purpose at which it aims. It is popular in style and evidently intended rather for the laity than for medical readers. Nevertheless, the newly qualified practitioner might benefit by its perusal, if only by being led to recognise the existence of numberless details of nursery hygiene upon which he may have to give an opinion.

LIBRARY TABLE.

The World's Classics.—Vol. lxxix., *Sheridan's Plays*, with an introduction by JOSEPH KNIGHT; vols. lxxxix. and xc., *The Professor at the Breakfast Table* and the *Poser at the Breakfast Table*, by OLIVER WENDELL HOLMES, with introduction by W. ROBERTSON NICHOLL; vols. xci. and xcii., *Pendennis*, with an introduction by EDMUND GOSSE; vol. xciv., *Scott's Lives of the Novelists*, with an introduction by AUSTIN DOBSON; vol. cxl., *The Works of EDMUND BURKE* (vol. iii.), with an introduction by FRANK H. WILLIS. Herfrowde, Oxford University Press. Price 1s. per vol. i bound in cloth.—These seven volumes are a further instalment of the excellent series some former members of which we reviewed in our issue of Dec. 22nd, 1906. Three of them—namely, that by Sheridan and the two by Wendell Holmes—are known to everyone but we expect that few of the present generation have read either Scott's "Lives of the Novelists" or any speech of Burke. The Public Schools Year Book for 1907. London: Swan Sonnenschein and Co. Pp. 533. Price 3s. 6d. net.—This, the eighteenth issue of this useful annual, contains particulars of all public schools connected with the headmasters' conference, together "with a few carefully weighed and necessary exceptions." It contains a variety of educational information which should be found indispensable by nearly all parents or guardians.

The Schoolmaster's Year Book and Directory, 1907. London: Swan Sonnenschein and Co. 1907. Pp. 574. Price 6s. net.— This annual publication is to the teaching profession much what the Medical Directory is to the medical profession. A consideration of this work and of the one previously noticed rather leads the reader to the conclusion that there is in this country too much teaching and too little learning, for the practical results seem by no means commensurate with the money and the brains which are spent upon teaching, or rather, we should say, upon education, two terms which are by no means synonymous.

Atlas of Cutaneous Morbid Histology. Consisting of 53 coloured figures on 24 plates and text. By MAX JOSEPH, Physician for Skin Diseases in Berlin; and J. B. VAN DEVENTER, Oberstabsarzt (Surgeon-Major) of the Netherlands East Indian Army in Batavia, Java. London: Archibald Constable and Co., Limited. 1906. Price 12s. net.—The names of the authors are sufficient to guarantee that the work before us has been prepared with great care and a

when, on removal of the plug of lint under an antiseptic rag, three ounces of turbid serum escaped. For the next three days there was scarcely any discharge, the deeper parts of the incision having cohered. On firm pressure, however, the product of seventy-two hours escaped, and amounted to four drachms of serum. Meanwhile the girl's general health, which had not been interfered with by the abscess, continued perfectly good, neither pulse, tongue, appetite, nor sleep having been disturbed.

In this case, though there is no deformity of the spine, there is great probability that caries of the vertebra is present. But even though such be the case, there is good reason to hope for a favourable issue. Regarding caries as merely the suppurative stage of chronic inflammation in a weak form of tissue, I have been not surprised, though greatly rejoiced, to find that it exhibits the tendency of inflammatory affections generally—viz., a disposition to spontaneous cure on the withdrawal of irritation. Hitherto, in surgical practice, caries has had to contend against the formidable irritation of decomposing matter, which, under circumstances of weakness, is often sufficient to cause ulceration, even in the soft parts; yet, in spite of this irritation, caries is often recoverable in the child where the vital powers of all the tissues are stronger. If, therefore, this serious complication can be avoided, there seems nothing in theory against the probability that caries may prove curable in the adult. And even should portions of necrosed bone be present, as is not unfrequently the case, our experience of the treatment of compound fracture with carbolic acid has taught us that dead bone, if undecomposed, not only fails to induce suppuration in its vicinity, but is liable to absorption by the granulations around it.*

Such were the hopes which I ventured to express several months ago to my winter class. Since that time I have opened numerous abscesses connected with caries of the vertebra, the hip, knee, ankle, and elbow, and in all cases I have found the discharge become in a few days trifling in amount, and in many it has ceased to be puriform after the first twenty-four hours. Finally, three days ago—viz., on the 4th inst., (July, 1867,) I had the inexpressible happiness of finding the sinus soundly closed in a middle-aged man, in whom I opened in February last a psoas abscess, proved to be connected with diseased bone by the discharge, on one occasion, of an osseous spiculum. For months past he had persevered with the antiseptic dressing, although the discharge did not amount to more than a drop or two of serum in the twenty-four hours, well knowing by bitter experience that so long as a sinus existed the occurrence of decomposition might produce the most disastrous consequences; and at length our patience has been crowned with success.

Hence I no longer feel any hesitation in recommending the early opening of such abscesses, because, while they remained unopened, the disease of the bone is necessarily progressive, whereas when opened antiseptically, there is good ground to hope for their steady, though tedious, recovery.

The putty of the strength above recommended, though it generally fails to excoriate the skin, sometimes produces this effect when long continued. In such case it may be reduced in strength so that the oil contains only one part to five or six without disadvantage when the discharge is very small in amount.

The application prevents the occurrence of cicatrisation in the little sore caused by the incision, and perpetuates a trifling discharge from it. Hence it is impossible to judge whether or not the sinus has closed, except by examining it from time to time with a probe, which should be dipped in the antiseptic oil, and passed in between folds of the antiseptic rag. This may seem a refinement, but if we could see with the naked eye a few only of the septic organisms that people every cubic inch of the atmosphere of a hospital ward, we should rather wonder that the antiseptic treatment is ever successful than omit any precautions in conducting it.

The putty used in treating abscesses has proved very valuable in simplifying the treatment of compound fracture, and enlarging the range of its applicability, and also in dealing with incised wounds on the antiseptic principle. But I must defer a notice of these matters to a future occasion.

Glasgow, July, 1867.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.

Election of President.

AN extraordinary Comitia was held on March 25th, Sir RICHARD DOUGLAS POWELL, Bart., K.O.V.O., the President, being in the chair.

The PRESIDENT announced that the Sir Gilbert Blaine medals had been awarded to Staff-Surgeon J. W. W. Stanton, R.N., and Surgeon Bernard Ley, R.N.

The PRESIDENT then delivered the usual annual address, in the course of which he offered congratulations to those Fellows, Members, and Licentiates of the College upon whom Royal honours had been bestowed during the past year, and he also referred to the awards, medals, prizes, and scholarships conferred or awarded by the College. He next mentioned the lectures which had been delivered before the College. The gifts presented to the College were likewise gratefully acknowledged. The President laid stress on the services rendered by the Harveian Librarian (Dr. J. F. Payne) in improving and maintaining the library of the College in every way. He then read short obituary notices of those Fellows who had died during the year: Henry Augustus Goodrich, Sir Willoughby Francis Wade, John Henry Bryant, John Henry Bridges, John Cameron, Thomas Harris, Gustave Lodore Schorstein, Edmund Symes-Thompson, and Arthur Ernest Sansom. The President then referred to the congresses held during the year to which the College had sent delegates, and to the communications which had taken place with various departments of State. The financial position of the College, separate and conjoint, was then reviewed. In conclusion, he expressed his thanks for the kindly courteous consideration shown to him by the College during his year of office, and he thanked all the officers, notably the Registrar (Dr. E. Liveing), for the assistance which they had given to him.

Dr. F. W. PAVY proposed a vote of thanks to Sir Richard Douglas Powell for the address which he had just delivered and for the services which he had rendered to the College during his year of office and added a request that the address might be printed.

Sir RICHARD DOUGLAS POWELL returned thanks to the College and acceded to the request to have the address printed. He then vacated the chair.

The REGISTRAR read the by-laws relating to the election of President. The ballot then took place and Sir Richard Douglas Powell was re-elected by a very large majority as President for the ensuing year.

The charge was delivered by the SENIOR CENSOR (Dr. F. T. Roberts) who delivered to Sir Richard Douglas Powell the insignia of office and the PRESIDENT pledged his faith to the College.

Sir RICHARD DOUGLAS POWELL then thanked the College for the honour accorded to him in so cordially re-electing him as President.

The following communications were received: (1) From the secretary of the Royal College of Surgeons of England reporting proceedings of its Council on March 14th; and (2) from Mr. A. Forbes Sleeking requesting that he might have access to the records of the College in compiling a biography of his father, the late Sir E. H. Sleeking. The request was granted.

A report from the committee of management dated March 4th was received and adopted. The committee recommended that the following institutions should be added to the list of those recognised by the Examining Board in England for instruction in chemistry, physics, and biology: Ley's School, Cambridge, and Trent College, Long Eaton.

The quarterly report of the examiners for the Licence on the results of the January examinations was received and adopted.

The PRESIDENT then dissolved the Comitia.

WEST CORNWALL MINERS' AND WOMEN'S HOSPITAL.—On March 23rd Lady Olifden formally opened in the presence of a large gathering a new operating theatre which has been added to the Miners' Hospital at Redruth. The theatre, which is fitted up with all modern improvements, has been erected at a cost of £1460, the whole of which sum has been subscribed.

Looking Back.

FROM

THE LANCET, SATURDAY, July 27th, 1867.

ON A

NEW METHOD OF TREATING COMPOUND FRACTURE, ABSCESS, ETC.

BY JOSEPH LISTER, Esq., F.R.S.,

PROFESSOR OF SURGERY IN THE UNIVERSITY OF GLASGOW.

PRELIMINARY NOTICE ON ABSCESS.

In anticipation of the more detailed account which I hope will soon appear in THE LANCET, I will now give a description of a new method of treating abscess, which has afforded results so satisfactory that it does not seem right to withhold it longer from the profession generally.

It is based, like the treatment of compound fracture,* on the antiseptic principle, and the material employed is essentially the same—namely, carbolic acid, but differently applied in accordance with the difference of the circumstances. In compound fracture there is an irregular wound, which has probably been exposed to the air for hours before it is seen by the surgeon, and may therefore contain in its interstices the atmospheric germs which are the cause of decomposition, and these must be destroyed by the energetic application of the antiseptic agent. In an unopened abscess, on the other hand, as a general rule, no septic organisms are present, so that it is not necessary to introduce the carbolic acid into the interior. Here the essential object is to guard against the introduction of living particles from without, at the same time that a free exit is afforded for the constant discharge of the contents. The mode in which this is accomplished is as follows:—

A solution of one part of crystallised carbolic acid in four parts of boiled linseed oil having been prepared, a piece of rag from four to six inches square is dipped in the oily mixture, and laid upon the skin where the incision is to be made. The lower edge of the rag being then raised, while the upper edge is kept from slipping by an assistant, a common scalpel or bistoury dipped in the oil is plunged into the cavity of the abscess, and an opening about three-quarters of an inch in length is made, and the instant the knife is withdrawn the rag is dropped upon the skin as an antiseptic curtain, beneath which the pus flows out into a vessel placed to receive it. The cavity of the abscess is firmly pressed, so as to force out all existing pus as nearly as may be (the old fear of doing mischief by rough treatment of the pyogenic membrane being quite ill-founded); and if there be much oozing of blood, or if there be a considerable thickness of parts between the abscess and the surface, a piece of lint dipped in the antiseptic oil is introduced into the incision to check bleeding and prevent primary adhesion, which is otherwise very apt to occur. The introduction of the lint is effected as rapidly as may be, and under the protection of the antiseptic rag. Thus the evacuation of the original contents is accomplished with perfect security against the introduction of living germs. This, however, would be of no avail unless an antiseptic dressing could be applied that would effectually prevent the decomposition of the stream of pus constantly flowing out beneath it. After numerous disappointments, I have succeeded with the following, which may be relied upon as absolutely trustworthy. About six teaspoonfuls of the above-mentioned solution of carbolic acid in linseed oil are mixed up with common whitening (carbonate of lime) to the consistence of a firm paste, which is in fact glazier's putty with the addition of a little carbolic acid. This is spread upon a piece of sheet block tin about six inches square; or common tinfoil will answer equally well if strengthened with adhesive plaster to prevent it from tearing, and in some situations it is preferable, from its adapting itself more readily to the shape of the part affected. The putty forms a layer about a quarter of an inch thick; it may be spread with a table-knife, or pressed out with the

hand, a towel being temporarily interposed to prevent the putty from sticking to the hand or soiling the coat-sleeve. The tin thus spread with putty is placed upon the skin so that the middle of it corresponds to the position of the incision, the antiseptic rag used in opening the abscess being removed the instant before. The tin is then fixed securely by adhesive plaster, the lowest edge being left free for the escape of the discharge into a folded towel placed over it and secured by a bandage. This dressing has the following advantages:—The tin prevents the evaporation of the carbolic acid, which escapes readily through any organic tissue such as oiled silk or gutta-percha. The putty contains the carbolic acid just sufficiently diluted to prevent its excoriating the skin, while its substance serves as a reservoir of the acid during the intervals between the dressings. Its oily nature and tenacity prevent it from being washed away by the discharge, which all oozes out beneath it as fast as it escapes from the incision; while the extent of the surface of the putty renders it securely antiseptic. Lastly, the putty is a cleanly application, and gives the surgeon very little trouble; a supply being daily made by some convalescent in an hospital, or in private practice by the nurse or a friend of the patient; or a larger quantity may be made at once, and kept in a tin canister. The dressing is changed, as a general rule, once in twenty-four hours; but if the abscess be a very large one, it is prudent to see the patient twelve hours after it has been opened, when, if the towel should be much stained with the discharge, the dressing should be changed, to avoid subjecting its antiseptic virtues to too severe a test. But after the first twenty-four hours, a single daily dressing is sufficient. The changing of the dressing must be methodically done, as follows:—A second similar piece of tin having been spread with the putty, a piece of rag is dipped in the oily solution, and placed on the incision the moment the first tin is removed. This guards against the possibility of mischief occurring during the cleansing of the skin with a dry cloth and pressing out any discharge which may exist in the cavity. If a plug of lint was introduced when the abscess was opened, it is removed under cover of the antiseptic rag, which is taken off at the moment when the new tin is to be applied. The same process is continued daily till the sinus closes.

The results of this treatment are such as correct pathological knowledge might have enabled us to predict. The pyogenic membrane has no innate disposition to form pus, but does so only because it is subjected to some preternatural stimulus. In an ordinary abscess, whether acute or chronic, the original cause that led to suppuration is no longer in operation, and the stimulus that determines the continued pus formation is derived from the presence of the pus pent up in the interior. When an abscess is opened in the ordinary way this cause of stimulation is removed, but in its place is substituted the potent stimulus of decomposition. If, however, the abscess be opened antiseptically, the pyogenic membrane, freed from the operation of the previous stimulus without the substitution of a new one, ought, according to theory, to cease to suppurate, while the patient should be relieved from any local or general disturbance caused by the abscess, without the risk of irritative fever or hectic.

Such, accordingly, is the fact. Abscesses of large size have, after the original contents have been evacuated, furnished no further pus whatever, the discharge being merely serum, which in a few days has amounted only to a few drops in the twenty-four hours. Whether the opening be dependent or not is a matter of perfect indifference, the small amount of unirritating fluid being all evacuated spontaneously by the rapidly contracting pyogenic membrane. At the same time, we reckon with perfect certainty on the absence of all constitutional disturbance.

As an illustration, I may mention the last case which has come under my care. It is that of a young woman, twenty-five years old, with psoas abscess, which had of late been rapidly on the increase, and caused a large swelling below Poupert's ligament, communicating with a fluctuating mass, dull on percussion, reaching to a considerable distance up the abdomen, the femoral vessels being raised over the communication between them. Six days ago I opened, in the manner above described, the swelling in the thigh at the anterior part of the limb where it was nearest the surface, giving exit to twenty-seven ounces of pus, thin, but containing numerous large curdy masses. I introduced a piece of lint, dipped in the carbolic acid and oil, into the incision; and this prevented any discharge from escaping during the next twenty-four hours,

*See THE LANCET of March 16th, 23rd, and 30th, and April 27th of present year (i.e., 1867).

to the advantage of patients with simple fracture and are saved very largely from irritative fever and prolonged suppuration, to say nothing of pyæmia. The effect of the careful application of the acid on the opening of large abscesses is equally striking. The secretion of pus is almost immediately stopped. Thus in one case of psoas abscess, in which twenty-seven ounces of pus were let out, the future successive discharges were three ounces of turbid serum, and four drachms of serum, respectively. Mr. LISTEN's cases of abscesses connected with diseased bone go far to justify the hope that the use of carbolic acid will so favour the tendency of the bone spontaneously to heal, as to bring caries and large abscesses connected with it within the range of curable diseases. We need say no more to justify our estimate of the importance of Mr. LISTEN's communications on the surgical use of carbolic acid." The leading article, from which with pardonable pride we have made these extracts, formed the first introduction of Lord LISTEN's splendid work to the mass of his professional brethren. His views were not accepted immediately and every change in procedure which he adopted as his own experience grew larger, was welcomed by his opponents as a proof of the instability of the new doctrines. But the results achieved by himself and others working upon his lines were so marvellous that the opposition speedily became fitful and ineffective. Within less than ten years from the date when his first observations were made public Lord LISTEN had the satisfaction of seeing the whole practice of surgery in the world revolutionised in accordance with his teachings, and the happiness of knowing that he had actually contributed to the abolition of untold physical misery and the saving of countless human lives.

Medicine and the Public.

UNDER the title of "The Community of Interest of the Medical School and the Public" we have received a copy of a highly instructive address delivered at Yale University by Dr. W. W. KEEN who is professor of surgery in the Jefferson Medical College at Philadelphia and who has received the distinction of an honorary Fellowship from the Royal College of Surgeons of England and from the Royal College of Surgeons of Edinburgh. Dr. KEEN takes as the foundation of his argument what he regards as admitted fact—namely, that the fees paid by medical students can never be sufficient to maintain a medical school in the highest state of efficiency; and, on this basis, he declares that, while it is the business and duty of such a school to give to the public the best-educated practitioners in every department of medicine, and so to increase our knowledge of the science and art of medicine as to render the profession constantly more and more efficient, it is equally the duty of the public to provide all the needed facilities for the making of the best medical men and for the prosecution of original research in order that the medical school may render its best service to the community. Dr. KEEN told his audience, as we have told our readers on many occasions, that the joint work of a college and a teaching hospital is of enormously greater value to the public than the mere care of the sick

in a hospital with which no college is associated, and it is greatly to be regretted that this most simple and elementary of all truths has even now by no means sunk into the minds of the great majority of the non-medical persons by whom hospitals are financially supported. I see every year in the hospital, declares Dr. KEEN, scores or even hundreds of patients who go out happy and in comfort, restored to health, and to wage-earning power, and it gives me great pleasure to think about such cases. But when I look at the hundreds of young men whom I have the pleasure of teaching, when I remember that I can instill into them high ideals, when I can bring into their lives the research habit and the desire to learn, and remember that they will go all over the world and cure hundreds, nay, thousands, more than I can, which work is the greater? the curing of my scores of patients or the teaching of hundreds of young men to go out to cure their scores of thousands, and to bring the blessings of many upon their heads for the work that they have learned to do through me? Hence, as medical education becomes every year more and more expensive, and inasmuch as medical students are largely drawn from classes who are not overburdened with wealth, Dr. KEEN regards the provision of educational facilities as being the greatest service which hospitals can render to the community and as the best and most charitable purpose to which the funds of contributors can be applied. This is common sense and it is much to be regretted that so many persons in positions of influence should still be deaf to its appeal. You may, they say in effect, spend your money in curing A but you must not spend it in teaching B and C to cure all the other letters of the alphabet, letters representing sufferers who will never be able to obtain access to your wards and who, if we could have our way, would be left to the tender mercies of ignorance.

The causes which have produced the frequently antagonistic, and almost always unsympathetic and unpractical, character of the attitude of many benevolent persons towards medical education would afford a curious subject for research; and would probably, in the present day, be largely resolvable into Dr. JOHNSON's candid explanation of an error of his own as a consequence of "pure ignorance." The study of medicine, partly from its engrossing character and partly on account of the limited means of many of those by whom it is pursued, has somewhat tended towards divergence from that study of letters which has long given, and indeed still gives, the tone to public opinion. To those who regard the time spared from professional labours and spent in the pursuit of literature as wasted we commend the stately passage in which GIBBON describes the nobility of the SPENCERS as having been "enriched by the trophies of MARLBOROUGH," but "exhorts them to consider the 'Fairly Queen' as the most precious jewel in their coronet." It may be assumed that only a comparatively small number of the hundreds of lawyers, of clergymen, and of country gentlemen, who pass through the older English Universities, bring away from them any large amount of classical learning; but there will be few who do not bring away sufficient to give them a distaste, hardly distinguishable from contempt, for the jargon of counterfeit Greek which we lately likened to the

THE LANCET.

LONDON: SATURDAY, APRIL 6, 1907.

The Eightieth Anniversary of Lord Lister's Birthday.

THE eightieth anniversary of Lord LISTER's birthday occurs this month and, as we have already announced in our columns, it has been suggested that the event would suitably be commemorated by the republication of his scientific papers prefaced by a short biography. The biography should contain an account of the part played by the genius of LISTER in the development of our knowledge of infectious processes and the history of his efforts to obviate wound infection. It is not too much to say—indeed, it is recognised by the scientific world—that his work in these directions has revolutionised the whole of surgical practice, and has led to the saving of more lives and the prevention of more misery than it is possible to calculate. Lord LISTER's original papers, to which it is now proposed to give suitable publication, are scattered throughout the medical and scientific publications of this country. They are for the most part accurate observations of his personal labours, a fact which gives them a particular value from the biographical point of view. We are proud to remember that THE LANCET was one of the earliest mediums through which Lord LISTER approached the scientific world, while we were certainly among the first to recognise the enormous bearings upon medicine in its broadest sense that Lord LISTER's work might have. A meeting of the committee appointed to make a fitting recognition of the anniversary is being held as we go to press. The form and method to be adopted in the publication of Lord LISTER's papers is to be considered and an editorial body appointed to undertake the work.

We publish this week under the title of "Looking Back" a preliminary note upon what Lord LISTER 40 years ago termed "A New Method of Treating Compound Fracture, Abscess, etc." It has hitherto been our custom, in compiling notes upon bygone medicine from past numbers of THE LANCET, to make our quotations from numbers some 80 years old, the gap between our present-day knowledge and the science of the pre-Victorian era being a very obvious one. On this occasion we need look back but half that number of years to reveal to our readers not a gap but a yawning chasm. In 1867 we are back in a time when it was the rule for an open wound to heal up by a process of suppuration, when the unfortunate victims of a compound injury to bone or joint were submitted at once to amputation, for otherwise they ran such risks from septic fever that many more of them died than lived, and when in the surgical wards of a general hospital deaths from gangrene or pyæmia were regarded as things which had to be

expected—as inevitable drawbacks of hospital treatment. It was at this time that LISTER, then professor of surgery in the University of Glasgow, showed by a series of convincing papers, similar in bearing to the brief preliminary note which we reproduce on p. 952, of this issue of THE LANCET, that many of these terrible conditions could be avoided by a routine treatment, of which the application of carbolic acid to the exposed surfaces was the basis. A series of those papers were published in our columns during 1867 and 1868 and an editorial commentary upon them makes interesting reading at the present day. "Although," we wrote, "he (Professor LISTER) bases his surgical use of carbolic acid upon the researches of M. PASTEUR, the application of these researches to the case of compound fractures, opened abscesses, and other recent wounds, is all his own. The need for determining the value of carbolic acid and the best form and mode of using it is most urgent. It is most lamentable to think of the extent to which the best and most refined surgery of the time is being frustrated in our great hospitals and even in those but lately built. The mortality of compound fractures, of the graver amputations and operations, and of lithotomy in our larger hospitals, both provincial and metropolitan, is something frightful. And the occurrence of death with symptoms of blood poisoning is, unfortunately, not confined to cases of serious operation, but happens ever and anon in operations in themselves slight. This risk—the risk of blood-poisoning—is, indeed, now the one great opprobrium of surgery. There is no limit to the operative feats of surgeons, either to the refined skill with which they may be accomplished or to the toleration of them by the anæsthetised patient, but there is a miserable and serious risk in every case, especially in hospitals, of the occurrence of fatal after-consequences, against which—until now, at least—we have had little or no power of resistance." The operator of to-day would hardly consider that we had been accurate in saying of his father's or grandfather's operative feats that there was no limit to them, but he will recognise that the marvellous progress that has been made of late in this domain of medicine has been wholly due to the development of antiseptic surgery as introduced to the world by Lord LISTER, backed by the facilities afforded by anæsthetics.

Our appreciation of Lord LISTER's work from the beginning is further shown by the concluding words of the same article. It runs as follows: "Mr. LISTER's papers, which will be found in THE LANCET of the present year (March 16th, 23rd, and 30th, April 27th, and July 27th), go to show that, applied to bad compound fractures, carbolic acid, pure or diluted—Mr. LISTER prefers the pure,—prevents decomposition and suppuration; that though it acts as a caustic, it does so to only an unimportant degree, doing its principal execution on small septic organisms, and but very slightly affecting the vitality of the proper animal tissues; that it favours granulations, and by so doing often saves tissue—even bone, as in Case 5¹—to a most wonderful extent. As a consequence of these properties, patients with compound fracture are raised very much

¹ The reference is to a remarkable case of compound fracture of the leg in a child where extensive necrosis of the tibia appeared to have actually commenced, but where the antiseptic treatment saved both life and limb.

measure of compulsory notification, the necessity for which and the merits of which have yet to be demonstrated. Dr. A. NEWSHOLME, the medical officer of health of Brighton, in a valuable paper showed it to be clear that a knowledge of the distribution of the condition is necessary before co-ordinated measures for its control can be undertaken, while the real utility of the notification of pulmonary tuberculosis depends upon the purposes to which the data thus collected are to be put and the facilities which obtain locally for the assistance and not the persecution of the patients. For instance, it would seem that in Brighton, where a large number of the patients notified are invited to spend a few weeks' holiday at the isolation hospital as the guests of the corporation, encouraging results, in so far as the actual number of cases notified are concerned, have been obtained; indeed, in this sense, voluntary notification at Brighton has been attended with greater success than compulsory notification at Sheffield. At the former place the visits of the sanitary staff are confined to the homes of the patients and are not extended, so at least we gather from Dr. NEWSHOLME'S observations, to the factories and workshops in which the patients work. The Cambridge discussion was a thoroughly interesting one and we were glad to be able to record at some length the remarks of Dr. J. H. C. DALTON, Dr. DUNCAN FORBES, Dr. L. HUMPHRY, Professor SIMS WOODHEAD, and Professor HOWARD MARSH. The gist of the debate was, perhaps, a little too optimistic with respect to voluntary notification since no reference was made to the places, and they are many, at which such notification has been practically a complete failure. Possibly, too, it may be found that the real value of notification, whether voluntary or compulsory, will be to bring to light early cases of the disease and by this means to reduce the death-rate by the arrest of the malady. But, as Professor HOWARD MARSH observed, the discussion showed that the difficulties surrounding voluntary notification are not so great as some persons have believed, and an extension of the system should tend materially to increase our knowledge as to the methods by which that portion of the disease which is caused by means other than infected milk is spread. The recent pronouncement by the Royal Commission on Tuberculosis has, however, raised issues of the greatest interest and moment, and it is now clear that pulmonary tuberculosis will not be eradicated by attention to the human source alone.

The paper read by Mr. EDWIN T. HALL before the Architectural Association was largely descriptive of existing sanatoriums and constituted a useful contribution to our knowledge of this side of the question. It would have been well had he not referred to the "advance" and "growth" of pulmonary tuberculosis—terms which must have conveyed to his audience the impression that the disease was on the increase, whereas, as was pointed out by Dr. H. T. BULSTROPE in the discussion, the disease has been steadily decreasing in England and Wales for very many years past. The most important parts of Mr. HALL'S paper, as also of the comments made by Dr. T. GLOVER LYON, were those which dealt with the cost of sanatoriums. As is well known, the cost of certain institutions erected within recent years in this country has been somewhere about £1000 per bed, which is an alarming and practically

prohibitive one if general provision for tuberculous cases is contemplated. It should, however, be borne in mind that the institutions to which these remarks mainly refer were erected by private munificence and that consequently they are not open to the criticisms which might perhaps be directed against them had they been provided out of local or State funds. If, too, permanent memorials are desired they cannot well take the shape of tents or huts, and the public should have every reason to be grateful for the provision which has gratuitously been placed at their disposal. Possibly we have tended in the past to be influenced unduly by the German type of building. The proposal, however, to erect a sanatorium at a cost (exclusive, presumably, of site, water-supply, and furnishing) of about £25 per bed, brings the provision of these institutions nearer practical realisation, and although it will probably be found that, when all payments have been met and a sufficient amount of land secured to enable the patients to be occupied thereon, this figure will be materially exceeded, it will be well if an opportunity can be afforded for erecting such an institution. But it may be desirable that, before any such scheme is actually embarked upon, a visit should be paid by the promoters to Benenden, in Kent, where a sanatorium is in course of erection and nearly completed, under the auspices of the National Association for the Establishment and Maintenance of Sanatoria for Workers suffering from Tuberculosis. The cost of this sanatorium, as was pointed out during the discussion on Mr. HALL'S paper, is somewhere about £100 per bed, and the project is deserving of every investigation in that it is an attempt to prove that sanatoriums once provided can be carried on by the workers themselves without any further appeal to the philanthropy of the public. There are, too, many other aspects of this scheme which should commend themselves to all serious students of the problem of tuberculosis. We have already suffered great disappointment from idle prophecies and ill-considered theories, and it is not too much to ask reformers to consider the mass of evidence under their hands to be sifted before they embark upon general counsels.

Innotations.

"Ne quid nimis."

HIGH ALTITUDES IN THE TREATMENT OF NERVOUS DISEASE.

WE have received a reprint of an article by Professor Nolda of St. Moritz on the value of high altitudes in the treatment of certain nervous diseases. A variety of observations have been made on the subject, including those of Erb, who wrote on "Winter Cures at High Altitudes," but few statistics have been forthcoming as to their value. Most of the Alpine stations with an altitude over 1300 metres, such as Arosa, Davos, Leysin, and Montana, derive the majority of their patients from sufferers with tuberculosis of the lungs, while St. Moritz receives also many sufferers from anaemia, chlorosis, and nervous conditions. Professor Nolda has observed 3000 patients of various nationalities suffering from nervous diseases and visiting St. Moritz. Those of Jewish origin predominate, but Slavs, notably Poles, and Romance nationalities, especially French, are also numerous. The next in number are Americans and Hungarians, while the Germanic races follow in the following

language of HUDIBRAS and which is affected by some modern medical writers. Such writers often deal with subjects which in their nature are difficult of comprehension by the lay mind and which therefore call for the most lucid exposition which the skilful employment of words of definite meaning can afford. It is largely, we believe, for the want of such exposition that the enormous practical results of modern medical science are still in great measure concealed from the apprehension of the public and that, save for occasional lip-service on special occasions, there is no real knowledge or recognition of what the medical schools, or the men proceeding from them, have accomplished even in quite recent years for the practical extension of the Empire and for the greater prosperity and greater safety of their fellow subjects.

In dealing with part of the question Dr. KEEN refers, in the first instance, to the victory of JENNER over small-pox; and his words appear to justify the belief that in America, as in Germany, the full fruits of that victory are secured and that they are not lost or imperilled, as with us, by the ignorant time-serving of politicians. He proceeds to the victory over yellow fever, by which the construction of the canal over the Isthmus of Panama has been rendered possible, and to that over diphtheria, by which the mortality from one of the most fatal of prevalent diseases has been reduced to the small percentage dependent upon neglected cases. In this enumeration it may be doubted whether he takes full account of the most splendid victory of all, that resulting from the general discovery of the agency of blood-sucking insects in the communication of disease and of the means by which, in due course of time, these insects may be destroyed. He does, indeed, couple the word malaria with yellow fever but the full meaning and the certain results of modern knowledge can scarcely be said to appear in their proper prominence upon his pages. The discoveries of MANSON and ROSS have pointed out the way to the effective opening of territories as large as Australia to the enterprise of merchants and colonists, have practically excluded "climate" from the difficulties to be overcome in tropical countries, and have substituted for it conditions which are controllable by the proper application of human agencies. The disappearance of the whole class of so-called "malarial" diseases from the countries infested by them, and the complete prevention of the terrible "sleeping sickness" and its analogues, are consequences now within measurable distance of achievement as results of medical education; and they are consequences at least as important to the human race as the discovery of America, or as the invention of steam locomotion either by land or sea. It will be a long time before the united energies of the whole tribe of politicians produce anything in the least degree comparable with them; and yet the bulk of the nation regards them not only without gratitude but without any conscious appreciation either of their magnitude or of their character. Quite recently the *Times* contained a letter from Professor RONALD ROSS describing the treatment received by Mr. HAFFKINE at the hands of the India Office, treatment only rendered possible by the existence of conditions which Professor ROSS vigorously describes. In India, in 1893, he tells us, both medical and

sanitary administration were in the hands, not of men of distinguished scientific ability, but of ordinary officials climbing upwards by seniority. The country lagged years behind other countries in the scientific study of disease. Discoveries made years previously in connexion with cholera, typhoid fever, malaria, filariasis, and dysentery were looked upon with easy scepticism or even contempt, no adequate public measures being taken to verify or to utilise them; and true scientific work was received with little encouragement or even with persecution. Of such treatment Mr. HAFFKINE has now been the latest example; and, as Professor ROSS declares, unless redress be speedily afforded, India and her rulers will stand convicted of indifference to science, stupidity, injustice, and gross ingratitude to one of their greatest benefactors. Nor, he tells us, has this been the only instance in which these qualities have been displayed towards distinguished but defenceless workers. It is manifest that their prevalence can only be explained on the hypothesis of a most suggestive ignorance at high quarters with regard to the nature of science and to its value in preserving the health and lives of the community.

The Control of Pulmonary Tuberculosis.

PERHAPS the most difficult administrative problem with which preventive medicine is face to face at the present time is that of the control of pulmonary tuberculosis, a disease which yearly claims such a substantial number of able-bodied adults whose labour and health are of far-reaching economic importance to the community. This difficulty is, no doubt, enhanced by the fact that there are constantly arising what may be regarded as false prophets who claim that by adopting the methods which they recommend the disease in question may be made to disappear in an astonishingly short space of time. Again, there are those who are prone to apply to the problem the same arguments and, except for vaccination, the same methods as are applied to small-pox, and who apparently hold the opinion that all those who suffer from pulmonary tuberculosis, even in its initial stages, should be separated from their friends until complete recovery or death. Obviously, having regard to the enormous prevalence of recognised and unrecognised tuberculosis, such a programme is impracticable and those who advocate it do not, we think, evince a due regard either for the teachings of epidemiology or the experience of administration.

But we cannot in this article discuss all the numerous proposals which have from time to time been presented for serious consideration, and we shall limit our references to the notification of the disease and the provision of sanatoriums, both of which may be regarded as within the limits of practicability and both of which have recently been the subject of useful papers and discussions, the former before the Cambridge Medical Society,¹ and the latter before the Architectural Association in London.² The debate at Cambridge was helpful, in that it accentuated the fact that a large amount of useful work may be carried out in connexion with the control of the disease without the extreme

¹ THE LANCET, March 16th, 1907, p. 736.
² THE LANCET, March 30th, 1907, p. 504.

waiting-rooms themselves, where the superannuated sofas—thanks to the overheated atmosphere diffused from ill-regulated *caloriferes*—give out again all that they have absorbed from relays of sitters, many of whom are the reverse of fanatical on the score of personal ablation. The buffets, too, at which a hasty meal may be snatched or a more leisurely repast consumed in expectation of a train 'in ritardo' are not always supplied with such food or drink as the invalid or even the healthy subject can safely indulge in—tinned meats or "preserved" vegetables or portable soups of uncertain date often entering into the menu. The same may be said of the wines and the mineral waters, not invariably an innocuous alternative to the so-called 'acqua potabile' of subsoil origin! The British press, professional and lay, to which Italy appeals for countenance in carrying through her much required railway reforms, has done much, and may do still more, in impressing upon the central authority at Rome the urgent need for making passenger traffic less fraught with discomfort and risk and less, by consequence, of a deterrent. There have been this season, it is said, fewer arrivals from the British Isles than Italy has known for many a day; but with the obstacles which she places in the path of her most welcome visitors, her press, headed by the Milanese journal, is more than justified in exclaiming '*Quid mirum!*'"

MILK-SUPPLY AND THE LONDON COUNTY COUNCIL.

ON the ground that many of the powers sought in the General Powers Bill, which stands for second reading in the House of Commons on April 11th, are controversial and would if retained delay the passage of the Bill the Parliamentary Committee has advised the Council to delete what are considered to be the contentious clauses. These include proposals relating to the sale of milk which were as follows: (1) to enable the Council to prohibit the sale of milk from any dairy situated within or without the county in which the medical officer suspects that cases of infectious disease within the county occurring in more than one sanitary district are attributable to the milk supplied from such dairy; (2) to enable the council to take samples of milk at railway stations and elsewhere in the county with the view of preventing the sale of milk unfit for human consumption; (3) to enable the council's medical officer to require dairymen to furnish lists of sources of milk and of their customers with a view of preventing the spread of infectious disease; and (4) to require dairymen to notify under penalty all cases of infectious disease among their servants and to prohibit any person suffering from an infectious disease from milking any animal, the milk of which is intended for consumption within the county. On the face of it, the decision of the Council to drop these clauses appears to be opposed directly to the canons of preventive medicine. Nothing is more certain than that contaminated milk is a very serious factor in the spread of infectious disease and therefore it is of the utmost importance that the public health should be jealously guarded by placing everything connected with the production and distribution of milk under an efficient system of control. It is, in fact, difficult to imagine any other clauses in the Bill which can relate to questions of greater importance. The Council's anxiety seems to be to get the Bill through the House this session, and the feeling apparently is that if the milk clauses are retained the chances of the Bill passing would be very remote owing to the opposition shown by all kinds of authorities. We are aware that county and municipal authorities have already large powers for dealing with the milk-supply, but it is obvious in the case of London that powers are wanted to deal with the milk at its source of

supply as well as at the distributing agencies. The Bill introduced by Mr. John Burns in the House of Commons a week ago does not relate to these questions, but merely seeks to sanction regulations for the supply of sterilised milk from municipal milk depôts without rendering the local authorities liable to surcharge by the official auditor.

AN IMPERIAL CONFERENCE ON HYGIENE AND TEMPERANCE.

IN order to stimulate general interest in the scientific teaching of hygiene and temperance as an integral basis of national education, and to bring before the country during the visit of the Colonial Premier trustworthy information as to what is done in various parts of the Empire, a committee, numbering among its members Sir Lauder Brunton, Sir Thomas Barlow, Mr. A. Pearce Gould, Sir Victor and Lady Horsley, Mr. W. McAdam Eccles, Surgeon-General G. J. H. Ivatt, Mr. C. H. Watts Parkinson, Mr. A. W. Mayo Robson, Dr. E. Claude Taylor, and Professor G. Sims Woodhead, has been formed to convene a Conference on the Teaching of Hygiene and Temperance in the Universities and Schools of the British Empire on St. George's Day, April 23rd. The conference has the approval of Lord Elgin, Secretary of State for the Colonies, who has promised to attend if his engagements at the Colonial Conference permit. Lord Strathcona and Sir John Gorst will respectively take the chair at the morning and afternoon sessions. Arrangements have been made for officially appointed educational experts to describe colonial systems of teaching the two subjects, while papers will also be read by leading continental *savants*. Further information and tickets of admission may be obtained from the honorary organising secretary, Miss St. John Wileman, 11, Chandos-street, Cavendish-square, London, W.

PRECIPITINS.

THAT scientific discoveries apparently most recondite and far removed from practical application may ultimately prove of great commercial or technical value might be demonstrated by innumerable examples. One such is seen in the application of the recently discovered precipitin reaction of Tschistovitch to medico-legal investigation. When the blood of one species of animal is injected into the body of an individual of another species it is found that the serum of the latter acquires the property of giving rise to a precipitate when added to a solution of the serum of the former or to a solution of any albuminous material derived from that species. By this means it is possible to identify, for example, bloodstains as human which by microscopical examination could only have been certainly ascertained to be of some mammalian origin. The reaction is indeed not absolutely specific, since blood from a nearly allied species—e.g., apes—may give a somewhat similar result, but it is not difficult to distinguish the two by quantitative tests. The precipitin reaction is now definitely recognised as a medico-legal test of great value in countries so diverse as Germany, Austria, the United States, Egypt, and Roumania. No instance of its employment in this country appears to be recorded. But the value of the reaction is not confined to this field. Its delicacy is such that it far surpasses the ordinary methods of proteid coagulation as a chemical test for these substances; it may be applied to detect adulteration in food materials, and has been employed by the biologist as a proof of a true group-relationship between animals of allied species. The interesting investigations of Professor D. A. Welsh and Dr. H. G. Chapman¹ have thrown a new light on the actual nature of the phenomenon of precipitation. They find that the substance precipitated is derived

¹ Welsh and Chapman: Proceedings of the Royal Society, B., vol. lxxviii., 1906.

order: Germans, Danes, Scandinavians, and English. The great majority of his patients were sufferers from neurasthenia, of which there were over 2000 cases. In those of recent origin due to anxiety, mental overwork, or following infectious diseases, alcoholism, and other intoxications, and traumatism lasting benefit is often derived from a stay of from four to eight weeks, but in older and more severe cases a stay of from four to six weeks in summer and a further stay in the winter are desirable. With regard to the effect of the high altitude on the individual symptoms, the headache and vertigo usually disappear within the first few days; the insomnia, however, often persists until the end of the period of acclimatisation, which is usually of from six to 12 days, but sometimes sleeplessness may go on for two or three weeks, which Professor Nolda does not regard as a contra-indication, but if the condition still persists after three weeks he sends such patients to lower levels. On the whole, he finds that 90 per cent. of neurasthenics with insomnia sleep better at high altitudes. The hypochondria associated with the disease usually becomes much less or disappears and Professor Nolda disagrees with the view of Krafft-Ebing, who regarded mental disturbance as a contra-indication. Mild degrees of cardiac neurosis, he finds, derive benefit from a mountain cure, but cases with dilatation or with marked arteriosclerosis should not be sent. Patients with migraine usually entirely lose their attacks from the day of arrival. Other visitors showing marked improvement are those with slight degrees of hysteria, melancholia, and epilepsy. Professor Nolda also finds that cases of spasmodic asthma of nervous origin derive much benefit, no less than 70 per cent. of them losing their attacks very shortly after arrival at St. Moritz, and in support of this he finds that the disease is absolutely unknown amongst the native-born inhabitants. It is a familiar fact that the Alpine health resorts owe a great deal of their vogue among those whose ordinary occupations are strenuous and exacting to the clear, rarefied atmosphere and to the exhilarating effects of the meteorological conditions found there, and it might *a priori* be expected that in conditions of moderate neurasthenia and the functional nervous, cardiac, and digestive derangements associated with it, such surroundings would be beneficial, but it should also be borne in mind that many such conditions are the result of overwork or over-stimulation, and that therefore enforced rest under as favourable conditions as possible is the rational form of treatment. It would seem therefore that high altitudes should be recommended in the first instance to mild cases or, as an after-care, in more severe conditions.

SENTIMENT AND HYGIENE.

It must be admitted that in many instances hygiene is directly opposed to sentiment and *vice versa*. The passing of the chalice or the loving cup from mouth to mouth is instinctively regarded as a process opposed to cleanly ideas, and medicine teaches how objectionable such a proceeding is and how it may easily hand on disease. But sentiment wins at every city dinner. Hygiene declines to agree with the sentiment that we must not dust an old bottle of port or claret covered with cobwebs and mould and removed from a cellar which must contain a deposit alive with, it may be, appalling bacteriological potentialities. Hygiene, again, would condemn the highly seasoned and oil-stained meerschaum or briar pipe, but sentiment says there is no pipe like it for a cool, well-flavoured, and pleasing smoke, besides which such a pipe has numberless associations, and the very sight of it recalls pleasant personal experiences. Hygiene dictates the removal of all so-called dirt films and the bringing to light of an exquisitely cleaned and smooth

surface whereon no bacteria can find lodgment; sentiment prefers the tone and dignity of deposit and loathes a brand new stone, brick, or tile. Hygiene would dispense with curtains and carpets and bid us live in rooms with walls and floors polished like a well-appointed dairy. To these things the sentiments of some people, at all events, naturally object. Hygiene has long attempted to banish the open fire, but sentiment has strongly, and so far successfully, resisted this attempt. Neither must there be smoke in the landscape if hygiene has its full sway, whatever art or sentiment may say. We cannot be found as advocates, however faint, of the smokiness of London, but the painters and etchers of less murky cities are never tired of pointing out the æsthetic possibilities of our capital with its blurred outlines and suggestive shadows. Hygiene would take away the jelly from the dietary because it is an excellent culture medium for micro-organisms; sentiment bids it stay. Instances could easily be multiplied. With hygiene there is no middle course. Its cry is sterilise, sterilise, scour, scour, but to sentiment sterilisation and scouring mean often a lost joy. How, then, can the strife between sentiment and hygiene be ended? Until knowledge is absolute it is impossible to say, for much that may be demanded in the name of hygiene now may be rescinded to-morrow because our sight is defective. Our consolation must be that in the great affairs of life hygiene does not necessarily make the world less beautiful, while the deference paid to well-founded sentiment increases with the improvement of our manners.

RAILWAY TRAVEL IN ITALY: ITS SANITARY DEFECTS.

"It is not only the vexatious unpunctuality, the defective accommodation, the frequent accidents due to inadequate personnel, that are evoking protests from the travelling public at home and abroad" (writes an Italian correspondent), "but the utter neglect of those sanitary observances and provisions which, always more or less in evidence in British, French, Belgian, Dutch, Swiss, and German railways, are conspicuously absent in those of Italy. Her most widely diffused journal—the *Secolo* of Milan—makes pointed reference to this shortcoming, beginning with the insufficient supply even of 'first aid' relief when one of the now too common collisions or 'deragliamenti' (derailments) occurs, the loss of time before the injured traveller receives professional assistance, and, when such is available, the lack of 'oggetti di medicazione' (surgical material), even of the means of transport from the scene of 'accident' to a place of shelter where adequate treatment is possible. In the strictly hygienic sphere, continues the *Secolo*, what has Italy done to make her passenger traffic safe or free from risk? Infective disease, most of all tuberculosis so frequently conveyed in the person of the phthisical patient, finds many a 'candidate' in the unsuspecting traveller, thrust at the eleventh hour into a carriage overcrowded, overheated, subjected to no disinfecting process, though it may have an hour or two before been occupied by the sufferer from variola, from scarlet fever, or from diphtheria. Resorting to as she is by so many people in all stages of lung disease in quest of sunshine and warmth, Italy ought to have a reserve of carriages specially set apart for such cases. There are the sleeping-car, the dining-car, and the carriage for *dames seules*. Why not the special car, and the carriage for the invalid? Such, it seems, is not to be had except at a prohibitive price; and so the healthy traveller has to take his chance beside a tuberculous subject or a diphtheritic *vis-à-vis*. The stations, again, in which the belated traveller has to spend weary hours are often the seat of every sanitary risk, from the impure water-supply and the evil-smelling latrines to the

waiting-rooms themselves, where the superannuated sofas—thanks to the overheated atmosphere diffused from ill-regulated *calorifères*—give out again all that they have absorbed from relays of sitters, many of whom are the reverse of fanatical on the score of personal ablution. The buffets, too, at which a hasty meal may be snatched or a more leisurely repast consumed in expectation of a train 'in ritardo' are not always supplied with such food or drink as the invalid or even the healthy subject can safely indulge in—tinned meats or "preserved" vegetables or portable soups of uncertain date often entering into the menu. The same may be said of the wines and the mineral waters, not invariably an innocuous alternative to the so-called 'acqua potabile' of subsoil origin! The British press, professional and lay, to which Italy appeals for countenance in carrying through her much required railway reforms, has done much, and may do still more, in impressing upon the central authority at Rome the urgent need for making passenger traffic less fraught with discomfort and risk and less, by consequence, of a deterrent. There have been this season, it is said, fewer arrivals from the British Isles than Italy has known for many a day; but with the obstacles which she places in the path of her most welcome visitors, her press, headed by the Milanese journal, is more than justified in exclaiming 'Quid mirum!'

MILK-SUPPLY AND THE LONDON COUNTY COUNCIL.

ON the ground that many of the powers sought in the General Powers Bill, which stands for second reading in the House of Commons on April 11th, are controversial and would if retained delay the passage of the Bill the Parliamentary Committee has advised the Council to delete what are considered to be the contentious clauses. These include proposals relating to the sale of milk which were as follows: (1) to enable the Council to prohibit the sale of milk from any dairy situated within or without the county in which the medical officer suspects that cases of infectious disease within the county occurring in more than one sanitary district are attributable to the milk supplied from such dairy; (2) to enable the council to take samples of milk at railway stations and elsewhere in the county with the view of preventing the sale of milk unfit for human consumption; (3) to enable the council's medical officer to require dairymen to furnish lists of sources of milk and of their customers with a view of preventing the spread of infectious disease; and (4) to require dairymen to notify under penalty all cases of infectious disease among their servants and to prohibit any person suffering from an infectious disease from milking any animal, the milk of which is intended for consumption within the county. On the face of it, the decision of the Council to drop these clauses appears to be opposed directly to the canons of preventive medicine. Nothing is more certain than that contaminated milk is a very serious factor in the spread of infectious disease and therefore it is of the utmost importance that the public health should be jealously guarded by placing everything connected with the production and distribution of milk under an efficient system of control. It is, in fact, difficult to imagine any other clauses in the Bill which can relate to questions of greater importance. The Council's anxiety seems to be to get the Bill through the House this session, and the feeling apparently is that if the milk clauses are retained the chances of the Bill passing would be very remote owing to the opposition shown by all kinds of authorities. We are aware that county and municipal authorities have already large powers for dealing with the milk-supply, but it is obvious in the case of London that powers are wanted to deal with the milk at its source of

supply as well as at the distributing agencies. The Bill introduced by Mr. John Burns in the House of Commons a week ago does not relate to these questions, but merely seeks to sanction regulations for the supply of sterilised milk from municipal milk depôts without rendering the local authorities liable to surcharge by the official auditor.

AN IMPERIAL CONFERENCE ON HYGIENE AND TEMPERANCE.

IN order to stimulate general interest in the scientific teaching of hygiene and temperance as an integral basis of national education, and to bring before the country during the visit of the Colonial Premiers trustworthy information as to what is done in various parts of the Empire, a committee, numbering among its members Sir Lauder Brunton, Sir Thomas Barlow, Mr. A. Pearce Gould, Sir Victor and Lady Horsley, Mr. W. McAdam Eccles, Surgeon General G. J. H. Evatt, Mr. O. H. Watts Parkinson, Mr. A. W. Mayo Robson, Dr. E. Claude Taylor, and Professor G. Sims Woodhead, has been formed to convene a Conference on the Teaching of Hygiene and Temperance in the Universities and Schools of the British Empire on St. George's Day, April 23rd. The conference has the approval of Lord Elgin, Secretary of State for the Colonies, who has promised to attend if his engagements at the Colonial Conference permit. Lord Strathcona and Sir John Gorst will respectively take the chair at the morning and afternoon sessions. Arrangements have been made for officially appointed educational experts to describe colonial systems of teaching the two subjects, while papers will also be read by leading continental *savants*. Further information and tickets of admission may be obtained from the honorary organising secretary, Miss St. John Wileman, 11, Chandos-street, Cavendish-square, London, W.

PRECIPITINS.

THAT scientific discoveries apparently most recondite and far removed from practical application may ultimately prove of great commercial or technical value might be demonstrated by innumerable examples. One such is seen in the application of the recently discovered precipitin reaction of Tschistovitch to medico-legal investigation. When the blood of one species of animal is injected into the body of an individual of another species it is found that the serum of the latter acquires the property of giving rise to a precipitate when added to a solution of the serum of the former or to a solution of any albuminous material derived from that species. By this means it is possible to identify, for example, bloodstains as human which by microscopical examination could only have been certainly ascertained to be of some mammalian origin. The reaction is indeed not absolutely specific, since blood from a nearly allied species—e.g., apes—may give a somewhat similar result, but it is not difficult to distinguish the two by quantitative tests. The precipitin reaction is now definitely recognised as a medico-legal test of great value in countries so diverse as Germany, Austria, the United States, Egypt, and Roumania. No instance of its employment in this country appears to be recorded. But the value of the reaction is not confined to this field. Its delicacy is such that it far surpasses the ordinary methods of proteid coagulation as a chemical test for these substances; it may be applied to detect adulteration in food materials, and has been employed by the biologist as a proof of a true group-relationship between animals of allied species. The interesting investigations of Professor D. A. Welsh and Dr. H. G. Chapman¹ have thrown a new light on the actual nature of the phenomenon of precipitation. They find that the substance precipitated is derived

¹ Welsh and Chapman. Proceedings of the Royal Society, B., vol. lxxviii., 1906.

mainly from the antiserum, not from the albuminous material ("homologous proteid") with which it reacts. The actual solid content of precipitating antiserum is increased as compared with the normal serum from an animal of the same species. At present it is impossible to calculate the quantities of serum and homologous proteid which take part in the reaction by any simple chemical equation, but the observers just quoted see no reason to doubt that a definite chemical reaction does occur.

MEDICAL REFEREES UNDER THE NEW WORKMEN'S COMPENSATION ACT.

THE development of the scope of the Workmen's Compensation Act, 1906, which comes into force on July 1st next, by which it is estimated that 6,000,000 workers will come under its provisions who were not affected by the Act of 1897, has caused us again to review carefully the Act in the interest of the medical profession. We have on several occasions pointed out that the question of the regulations to be made by the Secretary of State for the Home Department is one of the greatest importance, but the question of the appointment of medical referees is, we venture to think, one of certainly not less moment. The medical referees under the new Act will be called upon to decide between the conflicting views of medical practitioners, to give opinions in obscure and difficult surgical cases, and their decisions are to be final; they are therefore to act as judges, from whose decisions there is no appeal. In these circumstances it is perfectly clear that the practitioners selected for these posts must be of sufficient recognised standing to possess the confidence of their medical confreres in the several districts. Medical men will willingly meet in consultation and place their considered opinions before a medical referee for final judgment and award where the medical referee enjoys a high professional position and reputation, but these qualifications are necessary if the decisions of the referee are to be accepted as satisfactory solutions of points in dispute. We trust that the Secretary of State will, in the appointment of medical referees under the Act, meet the wishes and requirements of the profession, so that the medical regulations may work smoothly and without friction.

DEATHS IN PUBLIC INSTITUTIONS

THE recently issued report of the Registrar-General calls attention to the fact that during the year 1905 no fewer than 91,597, or 17.6 per cent., of the deaths registered in England and Wales occurred in public institutions, including workhouses and workhouse infirmaries, hospitals, and public lunatic asylums. It is, moreover, pointed out that the average percentage of these institution deaths in the ten preceding years 1895-1904 did not exceed 14.6. The increase in the proportion of deaths in each of the three classes of institutions has, indeed, been marked and constant during the past 30 years. In 1875 the proportion of deaths registered in public institutions did not exceed 8.8 per cent., which was but half the percentage in 1905. It must, however, be borne in mind that the number of these public institutions in which deaths are recorded has more than doubled during the 30 years. The separate workhouse establishments have increased from 715 in 1875 to 816 in 1905; hospitals and infirmaries from 582 to 1833; and public lunatic asylums from 83 to 136. The proportion of deaths recorded in workhouse establishments increased from 5.6 per cent. in 1875 to 9.4 in 1905; the percentage of deaths in hospitals during the 30 years increased from 2.3 to 6.3, and in public lunatic asylums from 0.9 to 1.9. The number of hospitals in England and Wales has, it appears, more than trebled during the 30 years under notice, owing mainly

to the marked increase in the number of cottage and isolation hospitals during that period. The fact noted in the Registrar-General's report that 32,899 deaths were registered during 1905 in the 1833 hospitals included in his list affords an entirely inadequate indication of the constantly increasing benefit which these charitable institutions confer on the public through the self-denying and honorary services rendered by their surgical and medical staffs. It seems impossible to doubt that the steady increase of hospital accommodation and service is at least one of the factors in the persistent improvement in public health during the past 30 years.

SPARTEINE SULPHATE IN POST-OPERATIVE SUPPRESSION OF URINE.

IN the *Medical Record* of Jan. 19th the value of sparteine sulphate in the prevention and the treatment of post-operative suppression of urine is recorded by Dr. Stuart McGuire. Suppression of urine after an operation is found in cases where nephritis pre-existed owing to sepsis or cholamia. As it does not develop until 24 or 36 hours after the operation it would appear that it is not due to shock. A patient operated on for retention of urine or jaundice occasionally does well for two or three days and then suddenly passes no more urine, becomes listless, restless, and then develops a stupor, rapidly deepening into a coma, and ultimately dies with all the symptoms characteristic of uræmia. Dr. McGuire has a record of six cases in which sparteine sulphate was the means of saving the patient's life. The drug increases the blood pressure, makes the pulse slower and stronger, and acts as a powerful diuretic. Doses of from one to two grains are given hypodermically and are repeated every three to six hours. The action is manifest in 30 minutes after administration and lasts for from four to six hours. Its employment should not be delayed until suppression of urine occurs, since it is a prophylactic as well as a curative agent. Dr. McGuire prefers sparteine sulphate to the drugs of the digitalis type owing to its rapidity of action and the efficiency of the results. It is noteworthy that the dose recommended is large as compared with the doses usually given—viz., one-tenth of a grain. Dr. McGuire failed to obtain good results with the usual remedies for suppression of urine, including the administration of water by the mouth and rectum and under the skin, strychnine and nitro-glycerine, calomel and saline purgatives, hot packs, vapour baths, and counter-irritants.

EUGENICS AND DESCENT.

Mr. Brudenell Carter, in the current number of the *Cornhill Magazine*, writes a suggestive commentary upon the endeavour of Mr. Francis Galton to establish an ordered knowledge of the conditions of parentage such as might tend towards the improvement of future generations of men, that being a sufficiently near definition of the science of "Eugenics." Mr. Carter's light but learned essay will hardly be regarded by Mr. Galton's followers as encouraging, for he evidently believes that we know as yet so little, at any rate so little for certain, of the influences of heredity that we are not in a position to say what is or what is not an atavistic result, or where or when a "throwback" will occur. It is evident that to bring about a progressive improvement of the human race by a system of selective marriages would imply a total remodelling of our social theories and procedures, and before embarking upon such a revolution we have a right to ask those who press it upon us how far they can predict any surety of results to be obtained by selective mating. Taking into consideration the way that the world now lives, it is beyond the power of prophecy to foretell that the children of a good or successful man will display the qualities or virtues which their parents have displayed.

Modern civilisation has produced so many complications, the rise and fall of commercial fortunes is so much more rapid, the commingling of classes is so much more general and intimate, that the parental influence whether moral or social has not the force that it formerly had. Physically the advocate of selective breeding is upon strong ground, for the whole world joins with the medical profession in condemning the union of the physically unfit. But the whole world also knows that we must not look to the heroes of muscular achievement as the ideal progenitors of a sane and well-balanced stock. We refer our readers to Mr. Carter's interesting article in which, writing from something of this point of view, he shows that before any method of scientific race production can be considered by the legislature it will at least be necessary, to quote his words, "that the laws of inheritance should be as firmly established as those of physics, and that the consequences produced by violations of them should have been brought home to successive generations by the hard teachings of experience."

THE INTERNATIONAL CONGRESS OF HYGIENE AND DEMOGRAPHY.

It is announced that the Fourteenth International Congress of Hygiene and Demography will be held in Berlin from Sept. 23rd to 29th. The meetings will not continue longer than till 2 P.M. each day in order that the afternoons may be devoted to visiting the numerous hygienic institutions of Berlin and its environs. There are more than a hundred such establishments which can be visited in this way, some of them without any restrictions and some by specially conducted parties. In order that the members of the congress may be able to select those in which they happen to feel most interest a "Hygienic Guide" will be issued containing short descriptions of the various institutes in three languages. Dr. Ellsberger, privy councillor in the Department of Public Worship and Education, is the president of the local committee. The general secretary of the congress is Dr. Nietner, Eichhornstrasse 9, Berlin 9 W.

BRIGHT SUNSHINE.

DURING the last fortnight of last month the brilliance of the weather was extraordinary, as will be gauged from the following figures:—

Stations.	Number of hours.	Difference from average.
Aberdeen	160	+ 42
Scarborough	113	*
Harrogate	119	"
Blackpool	110	+ 55
Llandudno	116	+ 60
Torquay	136	+ 63
Bournemouth	134	*
Brighton	111	+ 44
Eastbourne	128	+ 62
Hastings	123	- 51
Folkestone	120	*
Margate	128	+ 63
Clacton	114	*
Lowestoft	121	*
Bath	136	*
London	90	+ 63

* No trustworthy average.

Such a general absence of cloud as is here indicated has not been experienced at the same time of year during the present generation and an excellent example is furnished of what the British climate would often be in early spring if anti-

cyclones, and not cyclones, were the prevailing weather systems. On the coast fog and mist were practically non-existent except for a brief time about sunrise, and it was only in London that that unwelcome and belated visitor exercised any appreciable effect on the number of hours of sunshine. Had the atmosphere in the metropolis been as free from smoke and dust as it was in the country there is every reason to suppose that in spite of the almost stagnant air during the latter part of the period, which in the actual circumstances rendered the fog possible, London would have fared nearly as well as did the resorts on the coast. As it was, the sunshine in London (Westminster) for the whole month—152 hours—was much higher than any experienced during March since the automatic records commenced in 1881. While there can scarcely be a doubt as to the healthy influence of the abnormal sunshine it is questionable if the absence of rain which invariably accompanies anticyclonic weather is an unmixed blessing. London and several other districts had no more than half the usual amount of rain during last month, and what is, perhaps, more serious still, the quantity that has fallen since Jan. 1st in the metropolitan area and many other localities in the south and east of England has been only about 50 per cent. of the ordinary amount.

CELLULITIS AND MYOSITIS OF THE ABDOMINAL WALL SIMULATING INTRA-ABDOMINAL DISEASE.

In the *Journal of the American Medical Association* of March 2nd Dr. J. M. Hitzrot has pointed out the close resemblance which may exist between inflammatory conditions of the abdominal wall and intra-abdominal disease—a subject which has received little attention. He relates the following case. A youth, aged 18 years, was admitted into hospital complaining of pain in the right side of the abdomen. He ate a heavy meal eight days before and awoke next morning with pain in the abdomen, at first diffused but later becoming localised on the right side. It was cramp-like and occurred in paroxysms. It disappeared for about three days, leaving only a dull ache in the right side. On the fourth day it returned in great severity to the right side, which gradually grew tender. At the onset the patient vomited and the vomiting recurred at intervals but was never distressing. The bowels were constipated but acted freely to medication. On examination the face was flushed, the pulse was 104, and the temperature was 103.6° F. The respiratory movements were limited above the umbilicus and were absent below it. The abdomen was slightly distended and everywhere slightly tender. In the right iliac region was a hard, readily defined, very tender mass, extending from the anterior border of the rectus well into the flank and from the level of the umbilicus to an inch from Poupart's ligament. In this area there was marked muscular rigidity. Gentle percussion over the mass gave a tympanitic note. Acute appendicitis with abscess was diagnosed. An incision was made over the mass through the external oblique muscle. A small quantity of sero-sanguineous, slightly purulent fluid was found on the internal oblique muscle, which was cedematous and rather indurated. On cutting through it considerable cedema and induration were found in the subperitoneal tissue and the peritoneum seemed swollen and cedematous. The peritoneal cavity was opened and the intestines and appendix were found to be normal. As the appendix was very long it was removed. The peritoneum was carefully closed. The muscular and fascial layers were closely approximated, a drain was inserted at each angle of the wound down to the peritoneum, and the wound in the skin was closed with silk. A reddish grumous discharge of pus and muscle cells took place for about 12 days and the wound broke open. The discharge then

gradually ceased and the wound rapidly granulated. Recovery was uneventful. From the wound at the time of operation the staphylococcus pyogenes aureus was obtained in pure culture. The indiscretion in diet, the abdominal pain, at first generalised and then localised on the right side, the accompanying vomiting and constipation, the subsidence of the pain after catharsis and return in greater severity, the fever, rapid pulse, and tender hard mass in the region of the appendix, all seemed to point to disease of that organ. The literature of such conditions of the abdominal wall is scanty. Hiller has reported the case of a woman, aged 23 years, who complained of occasional pain in the region of the gall-bladder for three and a half years.¹ For two months the pain had been more severe and the patient noticed a tumour which had gradually enlarged. On examination a smooth, somewhat moveable, easily palpable tumour of the size of a goose's egg was felt in the region of the gall-bladder, two fingers' breadth below the costal margin. It seemed to have a thin pedicle leading up under the costal margin and did not seem to be adherent to the abdominal wall. An operation for cholecystitis was performed but an abscess of the right rectus muscle infiltrating the adjacent muscles was found. No connexion with the peritoneum or ribs could be found. Allison has recorded a case of abscess of the abdominal wall simulating malignant disease of the transverse colon in a coloured girl, aged 18 years.² The region of the umbilicus was tender and showed a swelling which resembled malignant growth. On operation a tuberculous abscess was found between the rectus sheath and the peritoneum.

INFANT MORTALITY AND MILK IN THE PHILIPPINE ISLANDS.

A New York correspondent writes: "The annual report of the Bureau of Health of the Philippine Islands, from July 1st, 1905, to June 30th, 1906, has just been issued in the United States. This is the only Bureau of Health under the American Government and much excellent work has been performed in Manila and in other parts of the Philippine Islands by it and by the health boards which preceded it. Some three years ago the bureau began the systematic education of the public in matters pertaining to the care of infants. A committee of native physicians prepared a special bulletin and distributed it among the people. The bulletin contained the usual propaganda. Particular emphasis was placed on the value of proper feeding, and it was shown that mother's milk is the natural food for infants and that the next best substitute is cow's milk. Since the issue of the bulletin the consumption of milk in Manila has increased 500 per cent., but, alas, this has had no effect in checking infant mortality. The fault has been soon found to be in the lack of care exercised with regard to the vessels and receptacles in which milk is kept and the failure to take the precautions necessary to keep the milk fresh. Contamination also at the period of milking must be taken into consideration. Nearly 95 per cent. of the milk used is obtained from the carabao which is by nature a dirty animal. A sanitary code which it is hoped will become law soon provides that all milk-dealers in the Philippines shall register at the Bureau of Health and that all vessels or receptacles used by them to contain milk shall be made of smooth impervious material which is capable of being thoroughly sterilised, and provided with suitable covers. The code also provides against adulteration by insuring that all milk sold or offered for sale shall be at all times subject to examination and analysis by the Bureau of Health and

that diseased milch animals may be summarily condemned and destroyed. It is anticipated that there will be difficulty in getting the code transformed into law and that even then regulations will not easily be preserved intact. But in the end the health of the infants will surely be benefited."

THE CONSUMPTION OF ALCOHOLIC BEVERAGES.

A RETURN presented to Parliament by the Board of Trade gives some interesting particulars with regard to the consumption of alcoholic beverages in the year 1905. It is stated that in the United Kingdom the consumption of wine has been falling continuously since 1899 and in 1905 amounted to only a little more than a quarter gallon (0.27 gallon) per head. The average for the period 1901-05 is a little higher, being 0.32 gallon. The consumption of beer in this country shows some fluctuation. In 1891 the consumption of beer per head of the population amounted to 30.2 gallons, from which point it fell yearly until in 1894 it was 29.5 gallons. From 1894 it rose steadily until it reached 32.6 gallons in 1899, since which year it has again steadily declined, and in 1905 it amounted to not more than 27.7 gallons. In Belgium the consumption of beer per head of the population in 1905 was 40.8 gallons, and in Germany 26.3. During 15 years the consumption of spirits per head of the population in this country has followed nearly the same course as the consumption of beer, having been low (0.97 proof gallon) in 1894, from which point it increased yearly to 1.09 gallons in 1899 and to 1.11 gallons in 1900. It has since decreased each year to a total of 0.91 gallon in 1905. It is difficult to attach any exact meaning to these figures, but the common impression is that the amounts consumed vary directly with the spending power of the public. So long as wines of the light kinds are sold at an unreasonably high price so will the demand for ardent spirits, and especially whisky, be maintained, for whisky and soda water provide a stimulant which is cheaper than wine, and people do not concern themselves so much as to the æsthetic qualities of wines as they used to do, while the average purse is not so long as it used to be.

INTRA-ORBITAL INJECTIONS OF CYANIDE OF MERCURY IN SYMPATHETIC OPHTHALMIA.

A METHOD of treatment of sympathetic ophthalmia, which is claimed by the proposer, Dr. G. Valois, to have been practised successfully by him in several cases, has been published in Professor Galezowski's *Revue d'Ophthalmologie* (No. 1, 1907). One of the cases recorded is that of a child, aged seven years, who in playing with a knife inflicted on himself a severe penetrating wound of the cornea. Dr. Valois saw the patient on the evening of the same day, when there were blood in the anterior chamber and a large hernia of the iris. An iridectomy was performed and a part of the blood was removed. The case went on well for eight days, when suddenly the intra-ocular tension diminished, a zone of redness appeared surrounding the cornea, and pain was felt in the globe. Soon after the opposite eye became affected. The sclerotic reddened, the cornea presented a fine descemitis, and the iris ceased to respond to light. Enucleation of the injured eye was at once practised and 24 hours later all the symptoms in the sympathising eye were relieved. Ten days afterwards, when the patient was about to be discharged from the hospital as convalescent, a fresh attack of inflammation with descemitis supervened, large exudates in the form of a triangle appeared on the posterior surface of the cornea, and the iris could not be dilated with atropine. The eye was manifestly in great danger. Dr. Valois therefore promptly injected deeply two drops of a 1 per cent. solution of cyanide of mercury into the orbit of the enucleated eye. On the following

¹ Beiträge zur Klinischen Chirurgie, 1899, p. 826.

² Medical News, 1891, xxv., p. 217.

day the redness had diminished. Two days subsequently a second similar injection was made and it was observed that whilst the redness still diminished the desceinitis persisted. Ten days were now allowed to elapse, at the end of which time ten drops of the cyanide solution were injected. Four days after redness had disappeared and the subsequent progress of the case was in all respects satisfactory. An objection to this mode of treatment is the extreme pain caused by the injection.

EPIDEMIC CEREBRO-SPINAL FEVER.

SINCE our last issue there has been no special event to record in connexion with the epidemic of cerebro-spinal fever beyond the occurrence of sporadic cases in localities hitherto unaffected. In London a case has been removed from Shoreditch to the Eastern Hospital of the Asylums Board. Cases have been diagnosed at Hutton in Essex and at Tipton in Staffordshire, and fatal cases have occurred at Salford and at Ripley, near Derby. In Edinburgh seven cases have been notified as presenting suspicious features; four of these have been removed to a hospital, four patients have died, and 14 remain under observation. In Glasgow the conditions show no alteration. There has been an extension of the disease in Aberdeenshire. The first case in this county was mentioned in our issue of March 23rd, p. 826, as occurring in the Cluny district, and a niece of this patient has since been attacked at Kintore. A fatal case has occurred in Stirling. In Belfast the public health committee has decided to make no daily statement as to the progress of the epidemic but in future to give only a weekly return of the number of cases and the deaths that have occurred each week. Since the commencement of the outbreak in this city there have been 228 cases with 136 deaths.

THE REGISTRATION OF PLUMBERS.

AN interesting leaflet has reached us in reference to this subject, being a reprint of a discussion on the matter which has recently been taking place in the columns of the *Liverpool Daily Post*. Mr. W. D. Caröe, the Master of the Worshipful Company of Plumbers, points out that the propriety and utility of a system of registration of plumbers were first publicly debated in Liverpool, when the British Medical Association held its congress there in 1833, while in the following year, when the International Health Congress was held in London, the whole question of the means of insuring the qualification and responsibility of plumbers and the efficiency of their work in its sanitary relation was considered by a great gathering of plumbers, architects, and sanitary authorities. It was then seen that inferior work and appliances constituted in a great measure the cause of the falling into disuse of the apprenticeship system and the increase of untrained men in the ranks both of employers and employed. The education and registration of the plumber followed and at the present time we are happy to note that 14,000 plumbers have been enrolled upon the register. Much of the success of the Worshipful Company of Plumbers in this matter is no doubt due to the fact that the Company exists solely for the benefit of the public and the advancement of craftsmanship and that it is in no way concerned with trading or trade profits as such. The work of the Company would be easier and its benefits more widely spread if the public could be induced in their own interests to give employment wherever possible to registered plumbers only. The avoidance of structural defects in the dwelling-house is one of the most important factors in domestic hygiene, and the general health of the community is not a little dependent upon the way in which the plumber carries out his work. The concluding editorial remarks of the *Liverpool Daily Post* sum up the

situation exactly: "Really competent men would be certain to welcome a compulsory registration test. Incompetent men ought either to be compelled to make themselves competent or to be by law forbidden to practise."

A SESSIONAL meeting of the Royal Sanitary Institute will be held at the Parkes Museum on Tuesday, April 9th, at 8 P.M., when a discussion will take place on the Aim and Scope of Women's Work in Relation to Public Health. The discussion will be opened by Dr. H. Meredith Richards, medical officer of health of Croydon. General discussion is invited and Colonel J. Lane Nottter, R.A.M.O., chairman of the council of the institute, will preside.

THE spring meeting of the South-Eastern division of the Medico-Psychological Association will be held, by the courtesy of Dr. F. R. P. Taylor, at the East Sussex County Asylum, Hellingly, on Wednesday, April 17th, commencing at 12 noon.

A TELEGRAM from the Governor of Hong-Kong received at the Colonial Office on March 25th states that there were 3 cases of plague reported during the week ending March 23rd and 3 deaths from the disease.

THE RÔLE OF THE BLOOD PLASMA IN DISEASE.

BY HARRY CAMPBELL, M.D., B.S. LOND., F.R.C.P. LOND.,
PHYSICIAN TO THE NORTH-WEST LONDON HOSPITAL AND TO THE
HOSPITAL FOR DISEASES OF THE NERVOUS SYSTEM,
WELBECK-STREET.

VI.¹

THERAPEUTICAL DEDUCTIONS.

WE have seen what a large part the plasma plays in shaping the destinies of the organism: in determining the various phases of evolution, in promoting senile decay, and in setting up morbid processes. As regards the latter it is no exaggeration to say that the rôle of the plasma in the genesis of disease is all-predominating, and that the future of pathology and therapeutics is essentially bound up in this subtly complex fluid.

That the majority of the diseases which the physician is called upon to treat are plasmic in origin is made manifest by a glance at the appended list of disorders which are admittedly induced through the plasma. The classification adopted, though obviously not a logical one, suffices nevertheless for our purpose.

1. All the bacterially induced diseases, such as the exanthemata and allied affections—e.g., scarlet fever, measles, small-pox, typhus fever, typhoid fever, influenza, rheumatic fever, mumps, diphtheria, and cholera; such disorders as pneumonia, cerebro-spinal fever, infantile paralysis, acute ascending paralysis; a multitude of unnamed febriculae, including "common colds"; the various tuberculous affections—e.g., phthisis pulmonalis, tuberculous meningitis, tuberculous kidney; gonorrhoea and syphilis in its multitudinous manifestations.

2. All inflammatory affections, with the exception of those due to direct irritation from without (as may happen, for example, in gastritis, bronchitis, and dermatitis).

3. Diseases due to the introduction of poisons from without—e.g., alcohol, opium, tobacco, tea, lead, arsenic, and mercury.

4. Gout and those numerous allied affections grouped under the term "rheumatic," such as muscular rheumatism and fibrositis—e.g., lumbago.

5. Numerous non-gouty affections of the joints, such as pyæmic and syphilitic arthritis, rheumatoid arthritis, chronic rheumatism, and many allied arthritides, impossible at present to classify.

6. The various hormonio disorders—e.g., Graves's disease, myxœdema, Addison's disease, and acromegaly.

¹ Articles I., II., III., IV., and V. were published in THE LANCET of Feb. 2nd (p. 313), 9th (p. 375), and 23rd (p. 535), and March 16th (p. 754) and 23rd (p. 827), 1907, respectively.

7. Spasmodic asthma, megrim, and diabetes.
8. Infantilism, delayed or premature puberty, and premature senility.
9. Such well-known affections of the blood as purpura, scurvy, chlorosis, pernicious anemia, and leucocythæmia.
10. All the so-called "primary" degenerative affections of the nervous system, with the possible exception of such diseases as Friedreich's and those which are excited by excessive functioning; most functional nervous disorders, including insanity, megrim, neuralgia, headache, and those multitudinous minor nervous disturbances to which almost all civilised human beings are occasionally liable.
11. Practically all the organic diseases of the cardio-vascular system other than the congenital and those due to muscular strain. As instances of heart disease caused through the plasma may be mentioned the endocarditis, myocarditis, and pericarditis of rheumatic fever, the endocarditis of influenza and the exanthemata, the pericarditis of Bright's disease, and the fatty degeneration of the myocardium resulting from chronic alcoholism. How large a part the plasma may take in causing cardio-vascular disease is further shown by the phenomena of chronic Bright's disease.
12. Most diseases of the lungs, bronchi, and plasma. Consider the frequent involvement of these structures in the specific fevers, in gout, and Bright's disease; the frequency of bronchitis in improperly fed children; and the large part which tuberculosis plays in pulmonary and pleural affections.

Seeing, then, how dominating is the rôle of the plasma in disease, it follows that in every case which comes before him the physician should pay due regard to the condition of that fluid. Generally he will be safe in postulating some plasmic defect, and his chief concern should be to discover in what that defect consists, and having done this, to correct it. He should argue: "If I can bring about a normal condition of the plasma, I can make my patient well." Doubtless it is not possible to effect a complete cure when there is grave structural change; nevertheless it is remarkable to what extent even serious degenerative changes can be recovered from, provided a healthy state of the plasma is established. Consider, for example, how completely the patient can be cured of grave alcoholic neuritis if only he can be made to abandon his drinking habits.

The proposition "healthy plasma implies health" is in the main accurate. Exceptions may occur, for example, in such a disease as facial neuralgia resulting from a lesion of the Gasserian ganglion; but cases of this kind are comparatively rare and the physician may rest assured that he will seldom fail to cure his patients if he can establish a perfectly healthy condition of the plasma.

While assigning to the plasma this prominent rôle in disease I am not unmindful of the part played by the nervous system in pathogenesis, nor of the good which may be achieved through it. We should ever be careful to remove any reflex irritation, such as eye strain, that may be present, and to get all the good we can by mental treatment, be it through education, change of scene, suggestion, or what not. Yet even then, and when all is said and done, it will be found that it is largely through the plasma that the good effect is achieved.

MEANS OF CORRECTING THE PLASMA.

In every case of disease in which we believe the plasma to be abnormal the first question to ask ourselves is: What is the nature of the defect? Does it pertain to its nutrients, hormones, enzymes, or excreta, and if so, what is its precise character? Unhappily, we can but rarely answer this question with any degree of precision, though in the correct answer to it lies the key to the diagnosis and the treatment of most non-surgical diseases. I do not propose to enter into the various methods at our disposal for discovering plasmic defects here—that would be altogether beyond the scope of these papers. I must content myself with briefly indicating the different ways of correcting them when found. They may be grouped under the following heads: (1) methods directed to the digestive system; (2) methods directed to the excretory organs; (3) methods directed to the destruction of bacteria, or the neutralisation of their products; and (4) methods directed to the correction of defects in respect of hormones and enzymes.

Methods directed to the digestive system.—In our endeavour to bring about a healthy state of the plasma we shall find

that it is through the digestive system that we can generally work most effectually. This is because digestion plays a preponderating part in determining the composition of the plasma, for disorders of it lead not only to the impoverishment but (what is of much greater pathological import) to the poisoning of the plasma, and also because the digestive system, owing to its large bulk and the complexity of its functions, but still more to its wanton abuse, is very apt to be thrown out of gear; so much so, indeed, that a sound digestion is but seldom met with among the civilised, the majority of whom suffer in greater or less degree from indigestion toxæmia—a condition responsible for much ill health among us moderns. Be it remembered that sound digestion generally means sound plasma and thus sound health, while defective digestion always implies unsound plasma and consequently imperfect health. This dependence of sound health upon sound digestion has long been recognised. Among the Chinese our "How do you do?" is rendered by "How is your stomach?"

We shall the better realise the prominent part played by the digestive system in determining the composition of the plasma if we reflect that of the sum total of material agencies operating upon the organism from without—constituting, that is, its material environment—food occupies the first place; it is from the food that the tissues are built up, and it is from the food, together with oxygen, that the energy of the vital machine is derived. The conversion of this crude food into a form suitable for absorption and assimilation is a function of the first importance, one consuming a large share of the total energy expended by the organism, and requiring the constant activity of the most bulky system of organs in the body. This capacious system includes not only the liver and the pancreas, but some 30 feet of tubing furnished with many millions of glands, and it contains on an average no less than one half the total blood mass. Nor must it be forgotten that the function of the digestive glands does not end with digestion; they also furnish enzymes and hormones which, entering the blood, play a necessary part in nutrition.

Here I would point out that it is essentially through the digestive system that climate benefits health. In most diseases it may be said that the patient does best where his digestion is best. No doubt other factors come into play, especially in such affections as bronchitis and rheumatism, in which the good effect of climate is largely produced by the direct influence of the atmosphere upon the skin and mucous membrane. Nevertheless, it is essentially the digestive factor that we have to rely on in the climatic treatment of disease. It will be found, for example, that the benefit which a tuberculous child derives from a stay at Margate is in direct proportion to the improvement which takes place in the character of his motions.

It is imperative that the physician should realise how large a part the establishment of normal digestion plays in treatment. Not until he does will he be able to secure a full measure of therapeutic success, no matter with what branch of medicine he may decide to identify himself. For this reason the study of dietetics and indigestion should occupy a prominent place in the student's curriculum, and throughout the whole of his subsequent career be kept constantly in view. Nothing more forcibly shows the evils of ultra-specialism than the casual way in which these subjects are treated by many physicians. In whatever direction he specialises a physician must at least learn the best that is known of the diagnosis and treatment of digestive disorders.

Let me here cite an incident which gives point to these remarks. Fully imbued with the truth I have just sought to emphasise, a physician of my acquaintance has for some time past been devoting himself to the study of diet, and in this connexion he not long since made an examination of the jaws and teeth of that splendid collection of skulls contained in the museum of the Royal College of Surgeons. Now this greatly concerned an old friend of his who, having docketed him neurologist, declared that he was gravely jeopardising his professional success by not sticking to his neurological last, that his conduct in thus straying beyond his own proper field was strangely heterodox, not to say eccentric, for (thus ran the argument) what in the name of common sense can teeth have to do with nerves? My friend contends, not, I think, without reason, that in point of fact there is a very close connexion between the two, and he is satisfied that his excursions into the realms of dietetics and

microbiology have in no small degree enhanced his efficiency as a practical physician, and not the least so among those of his patients who suffer from nervous maladies.

Methods directed to the excretory organs.—When the blood contains poisons an attempt may be made to get rid of them by promoting excretion, and from the earliest days of medicine eliminants in the shape of purgatives, diaphoretics, diuretics, and emetics have been used for this purpose. With the exception of the first of these, however, it cannot be said that they are of much help in purifying the blood and even purgatives act rather by preventing the absorption than by promoting the elimination of poisons. Diaphoretics are of little value as blood purifiers. A "cold" can sometimes be stayed off by "getting the skin to act"—e.g., by wrapping the patient up in blankets or putting him in a warm bath; and the Turkish bath is occasionally of therapeutic service, though not so useful as the natural diaphoresis provoked by exercise. In uræmia diaphoretics are practically valueless, while as for such time-honoured practices as giving ammonium acetate in febrile states, few would contend that they can have any appreciable effect in ridding the blood of poisons. Nor can it be said that diuretics are any more valuable for this purpose, except in so far as they act by stimulating a failing heart and thus removing dropsical accumulations.

And just as we cannot get much help from eliminants in relieving toxæmia, so, on the other hand, it is only exceptionally that any marked degree of toxæmia is attributable to defective elimination of normal excreta, except, perhaps, in the case of constipation. The fact is, such excreta are rapidly run out of the blood and only tend to accumulate seriously when there is grave organic disease of the heart, lungs, or kidneys. In short, toxæmia results from the absorption of poisons from without, or from the undue production of poisons within, rather than from failure in the eliminating organs; and its treatment therefore should consist rather in the prevention of such absorption and such undue formation, or in treatment calculated to neutralise the poisons present, not in attempts to promote their elimination.

Methods of coping with bacteria and their products.—We now know that the human organism has special methods of its own for striking at pathogenic bacteria and their products, methods which have been steadily evolving from the very beginning of animal life. No branch of therapeutics holds out greater promise than that which is based on these natural methods. Treatment of this kind, rendered possible by the labours of such men as Pasteur, Behring, Koch, and Wright, is eminently scientific and rational. Before their time the treatment of bacterially-induced diseases was for the most part empirical. It is true that abscesses have long been treated by rational surgical means and that the treatment of typhoid fever by cautious dieting and of hyperpyrexia by the application of cold may be regarded as genuinely rational; but speaking generally, it must be conceded that, prior to the advent of the new system, the treatment of microbial diseases was essentially empirical, and very poor at that. In the case of such affections as pneumonia, diphtheria, and the exanthemata, our treatment, so far as any good has come of it, has essentially consisted, not in worrying the patient by fussy interference, but in leaving him severely alone and trusting to careful nursing. While we have been hugging ourselves with the belief that we have "pulled him through" by a specious litle of treatment, it is Nature who has all the time been doing stern battle with the malignant foe. And how ineffectual and stupid our worrying applications to the diphtheric throat now seem in the light of the modern serum treatment! How pathetically puerile our snickering treatment of pneumonia (on which whole libraries of treatises have been written), when we learn that at the crisis the opsonic index of the blood leaps upwards, in token that the great strategist Nature has completed her plans for the final phagocytic onslaught, which is to annihilate the pneumococci and thus remove the essential cause of the disease!

We have still a great deal to learn on the subject of immunity. So far as our present knowledge goes the means adopted by the host for coping with bacteria would appear to fall under two heads—those adapted (1) to destroy the bacteria; and (2) to neutralise the poisons which they

which engulf and digest them or by means of chemical substances. These latter are of several kinds and include the lysins which actually dissolve the bacteria (as happens, for instance, in typhoid fever and cholera), and the opsonins which so affect the bacteria as to render them an easy prey to the phagocytes.

2. The bacterial poisons are neutralised by the antitoxins, substances which have been administered with great success in diphtheria, tetanus, and botulism. These poisons, allied as they are to the foodstuffs, are capable of being linked on to the molecules of the living protoplasm, such assimilative union interfering with the normal vital activities of the cells. Now the antitoxins combine with the bacterial poisons and thus prevent the latter from entering into union with the cell protoplasm, thus giving time for the process of bacterial destruction to be carried through.

The treatment of bacterial diseases by the application of nature's own method consists for the most part in the administration of antitoxins and of substances calculated to increase the opsonic power of the blood. For this latter method we are indebted to the classic researches of Wright and Douglas. In order that this treatment may be successful the quantity of the substance administered has to be carefully regulated in relation to the opsonic index. By due attention to this particular Wright, Bulloch, and others have been able to obtain striking results in local tuberculosis, as well as in acne, furunculosis, and syphilis.

When we reflect what brilliant results have in so short a time been achieved by this method of treatment, may we not confidently anticipate a splendid future for it? Treatment by drugs, dating back though it does some thousands of years, has with a few exceptions yielded but barren results. It was hoped that great things would come from a study of their physiological action and that a reign of rational, as distinguished from empirical, drug treatment had by it been inaugurated; but, alas, such hopes have not been realised. While many useful drugs will doubtless be discovered in the future the treatment by drugs seems destined long to remain essentially empirical. At last, however, a method of treatment has been discovered which is in the truest sense of the term scientific and rational, based as it is on the very method nature herself employs.

Methods directed to the correction of defects in respect of hormones and enzymes.—Whenever disease is due to a hormonal or enzymic defect the treatment obviously consists in correcting that defect. To do this we must first discover its exact nature, and this is seldom possible in the present state of our knowledge. We know that myxœdema is due to deficient thyroid action and are able to cure the affection by the administration of thyroid extract. Certain cases of infantilism, again, are apparently due to some defect in the pancreas and can be greatly benefited, as Byrom Bramwell has shown, by means of an extract of this gland. On the other hand, though there are good reasons for concluding that Graves's disease, Addison's disease, and acromegaly are due to perverted hormonal function of definite tissues, the treatment of these diseases by the administration of an extract of the affected tissue has hitherto proved disappointing. Similarly, while evidence seems to point to the conclusion that pancreatic diabetes results from the absence from the blood of a pancreatic enzyme, no satisfactory treatment of that disease has yet been discovered. But although at present we can do but little for this (probably large) class of disorders, we may reasonably hope for greater success as our knowledge of their pathology becomes more accurate.

Conclusion.—The object of these papers has been to emphasise the great importance, from the point of view of treatment, of fixing the attention on the plasma. The whole art of healing consists in acting directly on brain and nerves (as by education, "suggestion," the removal of peripheral irritation) and in correcting a faulty plasma—neither more nor less—and we may sum it up in the aphorisms, "Tercè la mind and the nerves; correct the plasma." There is no form of medical treatment but is embraced by one or other of these injunctions, and of the two the second is much the more important. Had we a Temple of Healing over one of its doorways the words, *Nervus atque viscerum cura*, might fittingly be inscribed, but over the main portal in letters of gold should be placed the admonition—

Corrige Plasma.

² It is scarcely necessary to say that it is impossible to express these aphorisms in classical Latin, which has no word either for the "nerves" or the blood "plasma."

BRITISH MEDICAL BENEVOLENT FUND.

At the March meeting of the managing committee of this fund 22 applications for assistance were received and some amounting to £254 voted in relief to 21 of the cases. The deaths of three annuitants were reported and vacancies so created were filled from the list of selected candidates. Mr. E. Parker Young was re-elected chairman of the committee for the ensuing year.

An abstract of the cases relieved is appended:—

Widow, aged 49 years, of L.R.C.P., L.R.C.S. Edin., who practised in London. Quite unprovided for at husband's death three years ago and is unable to obtain regular employment on account of ill-health and a deformity. No children. Relieved three times, £22. Recommended by Mrs. Coulson. Voted £14, £2 immediately and £12 in monthly instalments.

Daughter, aged 68 years, of late L.S.A., who practised in Monmouthshire. For 36 years has earned a living as governess, companion, &c., but her health is now breaking up. Recommended by Dr. Miles Milley and Mrs. Louisa Anderson. Voted £12 in 12 instalments.

M.B. Lond., aged 70 years. Has practised for 40 years but is now quite incapacitated. No income; children only just self-supporting. Recommended by Sir John Tweedy and Dr. F. T. Roberts (Vice-Presidents). Voted £20 in one sum.

Daughter, aged 68 years, of late M.R.C.S., who practised in Yorkshire. Has maintained herself as a governess for many years but is now quite broken down in health and dependent on a small weekly allowance from a charity. Recommended by Dr. Hector M. Robinson, honorary local secretary, and by Mrs. Braithwaite. Voted £12 in 12 instalments.

Widow, aged 60 years, of L.R.C.P. Irel., who practised in Cheshire. Quite unprovided for at death of husband a few months ago and has recently undergone a severe operation. Recommended by Mr. J. Taylor. Voted £12 in 12 instalments.

Daughter, aged 62 years, of late M.R.C.S., who practised for many years in London. Since mother's death has been living on a small legacy which is now exhausted. Health very feeble. Recommended by Mr. Reginald Harrison, Vice-President. Voted £12 in 12 instalments.

Daughter, aged 47 years, of late M.R.C.S., L.S.A., who practised in Essex. Is an epileptic and practically incapacitated by the results of burns. Recommended by Dr. Walter Rosser, honorary local secretary. Voted £12 in 12 instalments.

Widow, aged 48 years, of L.R.C.P. Edin., M.R.C.S. Eng., who practised in Herefordshire and whose savings were exhausted by a long illness ending in death. For several years applicant has kept a boarding house which she is now compelled to give up on account of ill-health. No income. Five children, of whom only two are able to give a little help and two are quite dependent. Relieved four times, £60. Recommended by Surgeon-Lieutenant-Colonel W. B. O. Deebila. Voted £12 in 12 instalments.

Daughter, aged 51 years, of late L.R.C.P. Edin., L.S.A., who practised in Lancashire. No income; is allowed a few shillings a week by a friend. Used to be a dressmaker but lost her situation when her firm dissolved a few years ago and since then has been unable to obtain regular employment. Relieved twice £20. Recommended by Dr. Alfred Godson. Voted £10 in 10 instalments.

Widow, aged 57 years, of L.S.A., who practised in Suffolk. Only income £8 a year. Lets lodgings but has had her rooms empty all the winter. Five children; only one able to give a little help and two still dependent. Relieved five times, £60. Recommended by Dr. W. S. A. Griffith. Voted £10 in ten instalments.

Widow, aged 62 years, of M.D. O.M. Glasg., who practised in Cheshire. No income; practically dependent upon this fund and a few shillings a week given by the Ladies' Working Guild. Relieved seven times, £24. Recommended by Miss Farquhar. Voted £10 in ten instalments.

Daughter, aged 60 years, of L.R.C.P. Edin., L.S.A., who practised in London. Used to support herself by taking boarders but for the last few years has been in very bad health and is now dependent on two sisters who have to maintain themselves. Relieved twice, £16. Recommended by Sir Anderson Critchett, Vice-President. Voted £10.

Widow, aged 57 years, of L.R.C.P., L.R.C.S. Irel., who practised in London. Applicant was well provided for at her husband's death 13 years ago but soon lost everything through a fraudulent solicitor. Endeavours to maintain herself as a companion but during the past year has undergone four operations and is now in a very feeble state of health. Relieved twice, £20. Recommended by Messrs. W. and A. Gilbey. Voted £10 in one sum.

Widow, aged 68 years, of M.R.C.S., L.S.A., who practised in Somersetshire. For 20 years after husband's death applicant maintained herself as a cook-housekeeper but her health is now broken down. Relieved once, £12. Recommended by Mr. J. Gould. Voted £12 in 12 instalments.

Daughter, aged 55 years, of late M.R.C.S., L.S.A., who practised in London and Birmingham. No income; endeavours to support herself and an invalid sister by needlework. Recommended by Dr. J. E. Nevins, honorary local secretary. Voted £12 in 12 instalments.

Daughter, aged 57 years, of late M.R.C.S., who practised in Gloucestershire and was an annuitant of this fund. Is given a home in return for services but receives no salary. Relieved five times, £24. Recommended by Mr. O. H. Fowler. Voted £12 in 12 instalments.

Widow, aged 49 years, of L.R.C.P. Edin., L.S.A., who practised in Cumberland. Quite unprovided for at husband's death four years ago. Health indifferent. Five children, barely self-supporting. Relieved once, £10. Recommended by Dr. G. H. Hume. Voted £10 in two instalments.

L.R.C.P. Edin., M.R.C.S. Eng., aged 60 years, who practises in Surrey. For the last three years has been incapacitated by hemiplegia and consequently earnings average less than £1 a week. Seven children, the youngest being three years old, and only one self-supporting. Relieved four times, £27. Recommended by Deputy-Surgeon-General E. McKellar. Voted £18 in 12 instalments.

Widow, aged 63 years, of L.R.C.P. Edin., L.S.A., who practised in Glasgow. No income; allowed £10 a year by a charity. Has endeavoured to support herself for some years by taking boarders, but is obliged to give up on account of ill-health. Applicant's only daughter, a teacher, has been ill for the last four or five months, and it has been necessary to sell some of the furniture to meet unavoidable expenses. Relieved eight times, £26. Recommended by Sir Patrick Heron Watson and by Dr. Joseph Bell (honorary local secretary). Voted £12 in 12 instalments.

Widow, aged 46 years, of M.R.C.S., L.S.A., who practised in county Durham. No income; endeavours to support herself by sewing. Health indifferent; two children—a son just self-supporting and a daughter, a school girl. Relieved five times, £47. Recommended by Mr. Henry Power and by Dr. W. B. Winston. Voted £12 in 12 instalments.

Daughter, aged 51 years, of late M.R.C.S., L.S.A., who practised in London. No income; is allowed a few shillings a week by a sister; health too indifferent for regular employment but does needlework when able. Relieved nine times, £101. Recommended by Mr. W. Bramley Taylor. Voted £12 in 12 instalments.

THE SOCIAL AND PHILANTHROPIC SIDE OF A GERMAN CHEMICAL FACTORY.

In the social life of Germany much importance attaches to the various systems and organizations which have for their object the promotion of the welfare of the working classes. The principal ones have been made the subject of special legislation and are binding on all persons who come within the scope of their definitions, whilst others depend on voluntary effort or are the result of mutual understandings between employers and employed. The compulsory institutions of this kind are represented mainly by the State-controlled systems of insuring working people against sickness, accident, and other circumstances conducive to bodily infirmity, whilst the benefit clubs and other philanthropic schemes of several great industrial undertakings come under the second heading. Manufactures of various kinds in which chemistry plays a leading part exist in Germany on an immense scale, one of the leading businesses being that carried on at the colour works known as Die Farbwerke vorm. Meister Lucius und Brüning at Hoechst on the river Main, not far from Frankfurt in South Germany. The magnitude of this company's operations may be understood from a brief statement recently issued by it showing that in 1906 the manufacturing department employed 5000 workmen, 200 foremen, 190 chemists, and 60 technological experts, whilst the trading department had a staff of 340. The State-controlled system of insurance of working people against illness, of course, operates in this factory as in every part of Germany since June, 1883, but the firm had before that date put a similar scheme in practice and the modifications required by the new law were comparatively unimportant. The letters contributed to THE LANCET by our Berlin correspondent have frequently explained that of the funds for the State-controlled insurance against illness two-thirds are collected from the workers and one-third is added by the employers. Many other means were adopted by the firm for the benefit of their employees and recently a small volume, about half of which consisted of architectural plans and elevations, was published, showing what had been accomplished in this direction, arranged under the following heads:—Insurance against accident and illness (die Batriebskrankenkasse); the Emperor William and Empress Augusta Fund for invalid workmen, widows, and orphans (die Kaiser Wilhelm- und Augustastiftung); the foremen's pension fund (die Aufseher-Pensionskasse); the savings bank (die Sparkasse); the general aid (Unterstützungsfonds); baths, various mess-rooms (Speiseanstalten); general shop (Kaufhaus); workmen's dwellings; men's dormitories (Schlafäle); the school of domestic economy; the maternity hospital; music, instrumental and vocal; the library; the convalescent home; the homes for pensioned workmen (Arbeiterheim); and the pension fund of the staff (Beamten-Pensionskasse). As a selection from the above it may here be sufficient to give a few words of explanation with respect to (1) sick pay and the care of patients; (2) the Emperor William and Empress Augusta fund; (3) the pension fund of the staff; (4) workmen's dwellings; and (5) the maternity hospital.

1. Sick pay and the care of patients.—As regards sick pay, it may be remarked that the average wages of a skilled workman are 4 marks per day and the normal sick pay is 60 per cent. of the wages, when the latter do not exceed 4 marks, but in cases of exceptional necessity or accident without contributory negligence, the firm may pay full

are: (1) to provide pensions for men past work, as well as for their widows and children; (2) to lend sums up to 3000 marks at 4 per cent. interest and 2 per cent. redemption for the purchase of real estate (*Immobilien*); and (3) to lend sums up to 100 marks in cases of great necessity. The members of this fund are about 2000 in number; they pay no subscriptions but must have had five years' continuous service with the company.

3. *The pension fund of the staff.*—*Beamten-Pensionskasse* means the pension fund of what may be called in English the salaried staff (*Beamte*) as distinguished from the wage-earners. Membership of this fund is compulsory on all of this class who are not already members of the Emperor William and Empress Augusta Fund or the foremen's pension fund. It was founded in 1884 with a capital sum of 30,000 marks and its assets in 1906 were 2,015,000 marks.

4. *Workmen's dwellings.*—The erection of workmen's dwellings was commenced in the year 1875; in 1899 they numbered 380; in 1903 there were 536; and in 1906 there were 50 for salaried officials (*Beamte*) and 700 for foremen and workmen. These dwellings, built on the company's land, remain the property of the company in all circumstances, but the company encourages and assists workmen to acquire or build residences of their own in the neighbourhood (see Fig. 1). The house to the front and left side in the picture is for four families and cost 19,800 marks to build; each family has six rooms. The other is also for four families, each having three rooms. The rent of the company's dwellings varies from 2 marks 30 pfennig per week for a house of two rooms, kitchen, cellar, outhouse, and garden, to 4 marks 20 pfennig per week for one of five rooms, kitchen, cellar, outhouse, and garden. Most of the dwellings are semi-detached (*Doppelhäuser*), but some are detached (*Einzelhäuser*); others are divided into four, and others stand in rows. Repairs and necessary renewals are done by the company.

5. *The Maternity Hospital.*—This hospital (see Fig. 2) was opened in 1900, partly with a view to relieve the workmen's households from the inconvenience of confinements taking place at home, and more especially to prevent the mothers from leaving their beds and returning to domestic duties too soon. No charge is made to the patients. If help is required in the husband's house the company pays two-thirds of the expense incurred. In the hospital there are six rooms with two beds each, three rooms with one bed each, two lying-in rooms, and three bathrooms. The hospital is under the general supervision and control of the Government district medical officer (*Königlicher Kreisarzt*) in Hoeschst; the actual working staff is composed of a Red Cross sister from Wiesbaden, a deputy sister, and two midwives. The hospital is said to be well patronised (*vorübergehend schon voll besetzt*) by the workmen's wives, although the actual number of patients is not given.

From the above summary it will be seen that the persons employed in this factory enjoy a number of advantages unobtainable apart from a large and profitable business, the heads of which are disposed to do as much as possible for the welfare of their subordinates.

MEDICINE AND THE LAW.

An Unregistered Person practising Dentistry: the Alleged Attitude of the Home Office.

At Cockermouth recently James Evan Jordan was convicted and fined 1s. at the instance of the London and Counties Medical Protection Society for using titles implying that he was registered under the Dentists Act, 1878, or was specially qualified to practise dentistry. The titles used were "D.S., U.S.A., the American Dentist," which were upon a brass door-plate, and an advertisement in the *West Cumberland Times* contained matter to the same effect. The solicitor appearing for the defendant admitted the above to be facts and also that the defendant was not registered and had no qualification to be so, but stated that he was "a member of the Rhode Island Association and that he would be properly qualified in America." The fine of 1s. inflicted might appear to be light but for a circumstance narrated by the defendant's solicitor which will account to some extent for the attitude of the bench and which, if accurately described in the report of his speech in

the *West Cumberland Times*, must be characterised as remarkable. It had been suggested that the defendant had deceived the Cumberland county council but "the facts as regards that were these: seven or eight years ago Mr. Jordan was appointed dentist to the industrial school at Cockermouth. Some kind professional friends of his (he could not help thinking that these professional friends were the people who were really bringing them there to-day) wrote to the committee of the industrial school and informed them that Mr. Jordan was an unregistered dentist, and therefore not a fit person to hold the post of dentist to the school. The matter was referred to Mr. C. B. Hodgson, Carlisle, and from him to the Home Office. The Home Office were fully informed of the circumstances and they said that if the work was done by Mr. Jordan to the satisfaction of the committee the appointment was perfectly good and right." We should like to see copies of the correspondence alluded to before according absolute belief to every detail of a statement which amounts to this: that the Home Office would endorse the appointment, say, of a blacksmith as dentist to operate on the unhappy inmates of an industrial school, provided that the blacksmith drew teeth and otherwise attended to his patients to the satisfaction of the committee! If the statement made represents accurately the official opinion we should desire to refer the Home Office and the council in question to the whole of the legislation of the years which have gone by since the passing of the Medical Act, 1858, and of the Dentists Act, 1878. As far as we are aware, no recognition has ever been accorded to the appointment of any person to fulfil the functions of a medical man or dentist by any Act of Parliament except with the stipulation that the appointed person shall be a practitioner registered according to the law, but a mistake may have been made. We should be glad to be informed of the exact grounds upon which the defending solicitor in the case in question was able to claim the official recognition of the Home Office for the appointment of an unregistered person to practise dentistry upon the inmates of an industrial school, subject only to the test that the committee should be satisfied.

The Overlying and Accidental Burning of Children.

The Bill which has for its object the prevention of those unnecessary deaths of children which occur through their being left alone in rooms with unguarded fires, was commented on in THE LANCET of March 16th, p. 760, and about 1600 cases occur to illustrate the need for it in every year. One, however, which was investigated at an inquest at Hackney recently affords so good an instance of the kind of mother whose care for her offspring requires to be stimulated by law that it is worth referring to. The deceased was a child, aged three years, and his mother in giving evidence said that she went out shopping leaving him with another child, aged two years, in the back kitchen. There was an unguarded fire in the front room and he appears to have gone in there and set his clothing alight, with the result that he died from the consequent burns. "He was up to everything and she (his mother) had had to beat him hundreds of time." A mother whose only idea of training and protecting her child was to beat him can hardly complain if her management of her family is interfered with to some extent by law, and if she is compelled to purchase a fireguard the fact that she can afford to rent two rooms suggests that the purchase of such an article of a cheap but effective kind might be within her powers. Had the Bill referred to become law the mother in the case described might have been convicted of manslaughter.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 76 of the largest English towns 8544 births and 5168 deaths were registered during the week ending March 23rd. The annual rate of mortality, which had been equal to 18·4, 18·2, and 17·8 per 1000 in the three preceding weeks, further declined to 16·8 in the week under notice. During the first 12 weeks of the current quarter the death-rate in these towns averaged 19·1 per 1000, the rate during the same period in London being 19·3. The lowest death-rates in the 76 towns during the week were 9·1 in Willesden, 9·8 in Burton-on-Trent, 9·9 in Newcastle-on-Tyne, and 10·3 in

Handsworth; the rates in the other towns ranged upwards to 25.5 in Hastings, 25.9 in St. Helens, 27.7 in Middlesbrough, and 29.4 in West Bromwich. The 5156 deaths in the 78 towns showed a further decline of 320 from the numbers returned in recent weeks, and included 469 which were referred to the principal epidemic diseases, against 470 and 465 in the two preceding weeks; of these, 182 resulted from measles, 114 from whooping-cough, 59 from diphtheria, 49 from diarrhoea, 39 from scarlet fever, 26 from "fever" (principally enteric), and not one from small-pox. The deaths from these epidemic diseases were equal to an annual rate of 1.5 per 1000 in the 78 towns, the rate from the same diseases being 1.1 in London. No death from any of these epidemic diseases was registered in Norwich, Plymouth, Southampton, Swansea, or in 11 other of the 78 towns; the annual rate therefrom, however, ranged upwards to 3.9 in Smethwick, 4.4 in Birkenhead, 7.3 in St. Helens, and 8.3 in West Bromwich. The 182 fatal cases of measles showed a further decline of 17 from the numbers returned in recent weeks, but caused an annual rate of 3.1 in Smethwick, 3.4 in East Ham, 3.5 in Birkenhead, 6.8 in St. Helens and in West Bromwich. The 114 deaths from whooping-cough were equal to the number in the previous week, the highest annual rates therefrom being 1.9 in Tynemouth, 2.1 in Willesden, and 3.1 in East Ham. The 59 deaths referred to diphtheria also showed a further slight decline, but were proportionally most excessive in Walthamstow, Halifax, and West Bromwich. Neither scarlet fever nor "fever" showed marked prevalence in any of the 76 towns. Diarrhoea caused the greatest fatality in Devonport and Burnley. No case of small-pox has been under treatment in the Metropolitan Asylums Hospitals since the end of June last. The number of scarlet fever patients under treatment in the Metropolitan Asylums Hospitals and in the London Fever Hospital, which had steadily declined in the 12 preceding weeks from 3846 to 2826, further fell to 2734 in the week under notice; 312 new cases of this disease were admitted to these hospitals during the week, against 308 and 327 in the two previous weeks. The deaths in London referred to pneumonia and other diseases of the respiratory organs, which had been 432, 405, and 403 in the three preceding weeks, further declined to 353 in the week under notice, but exceeded the corrected average number in the corresponding week of the last five years by 15. The 22 deaths referred to influenza in London were four below the corrected average. The causes of 56, or 1.1 per cent., of the deaths registered during the week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Leeds, Sheffield, Bristol, West Ham, Newcastle-on-Tyne, and in 51 other of the 76 towns; the proportion of uncertified deaths, however, again showed a marked excess in Birmingham, Liverpool, Preston, Sunderland, and South Shields.

In 76 of the largest English towns 8117 births and 5450 deaths were registered during the week ending March 30th. The annual rate of mortality, which had been equal to 17.8 and 16.8 per 1000 in the two preceding weeks, rose again to 17.7 per 1000 during the week under notice. During the past quarter the death-rate in these towns has averaged 19.0 per 1000; the rate in London during the same period being 19.2. The lowest death-rates last week in the 76 towns were 8.0 in Willesden, 8.4 in Reading, 9.0 in King's Norton, 9.3 in Hastings, 10.5 in York, and 10.8 in Derby; in the other towns the rates ranged upwards to 24.6 in Swansea, 25.6 in Handley, 26.2 in Bolton, 27.1 in St. Helens, and 29.5 in Birkenhead. The 5450 deaths in the 76 towns showed an increase of 254 over the number in the preceding week, and included 559 which were referred to the principal epidemic diseases, against 465 and 469 in the two preceding weeks; of these, 233 resulted from measles, 175 from whooping-cough, 61 from diphtheria, 37 from diarrhoea, 33 from scarlet fever, 20 from "fever" (principally enteric), and none from small-pox. The deaths from these epidemic diseases were equal to an annual rate of 1.8 per 1000 in the 76 towns; the rate from the same diseases being 1.9 per 1000 in London. No death from any of these epidemic diseases was registered in Leicester, Burnley, Huddersfield, or in five other of the 76 towns; the annual rates ranged upwards to 5.5 in West Hartlepool, 5.7 in East Ham, 6.2 in St. Helens, and 11.0 in Birkenhead. The 233 fatal cases of measles showed a marked increase upon the number in the preceding week, and caused an annual death-rate of 3.8

in East Ham, 4.5 in West Bromwich, 5.6 in St. Helens, and 8.8 in Birkenhead. The 175 deaths from whooping-cough also showed an increase, the highest annual rates last week being 1.7 in Tottenham, in Leyton, and in Walthamstow, and 3.2 in Swansea. The 61 deaths from diphtheria were slightly in excess of the number in the preceding week, the greatest proportional mortality from this disease being recorded in Aston Manor, Coventry, and Wigan. The deaths from scarlet fever, from enteric fever, and from diarrhoea were below the average numbers in recent weeks, and were not excessive in any of the 76 towns. No case of small-pox has been under treatment in the Metropolitan Asylums Hospitals since June last. The number of scarlet fever patients in these hospitals and in the London Fever Hospital, which had continuously declined in the 13 preceding weeks from 3846 to 2734, had further fallen to 2637 at the end of last week; 330 new cases of this disease were admitted to these hospitals during the week, against 327 and 312 in the two previous weeks. The deaths in London referred to pneumonia and other diseases of the respiratory system, which had been 405, 403, and 353 in the three preceding weeks, were 354 during the week under notice, and were 31 above the corrected average number in the corresponding week of the five previous years. The 24 deaths from influenza in London were two above the corrected average. The causes of 43, or 0.8 per cent., of the deaths registered during the week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in London, West Ham, Portsmouth, Bristol, Leicester, Nottingham, Salford, Bradford, Newcastle-on-Tyne, and in 47 other of the 76 towns; the proportion of uncertified deaths, however, showed a marked excess in Liverpool, Birmingham, Sheffield, West Bromwich, Coventry, Warrington, and Sunderland.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in eight of the principal Scotch towns, which had been equal to 20.6 and 20.5 per 1000 in the two preceding weeks, rose again to 20.6 in the week ending March 23rd, and exceeded the mean rate in the 78 English towns by 3.8. The rates in the eight Scotch towns ranged from 14.9 and 16.5 in Aberdeen and Perth, to 20.1 in Dundee and 24.1 in Glasgow. The 715 deaths in the eight towns showed an increase of three upon the number in the previous week, and included 102 which were referred to the principal epidemic diseases, against 112 and 100 in the two preceding weeks. These 102 deaths were equal to an annual rate of 2.9 per 1000, which exceeded by 1.4 the rate from the same diseases in the 78 English towns; they included 48 which were referred to "fever," 33 to whooping-cough, 11 to diarrhoea, six to diphtheria, four to measles, and not one to small-pox or scarlet fever. The deaths referred to "fever," which had been 52 and 43 in the two previous weeks, rose again to 48 during the week and included 38 in Glasgow, five in Edinburgh, three in Leith, and two in Paisley; 33 of the 38 deaths from "fever" in Glasgow, four of the five in Edinburgh, and all those recorded in Leith and Paisley were certified as cerebro-spinal meningitis. The 33 fatal cases of whooping-cough corresponded with the number in the previous week, and included 30 in Glasgow and two in Edinburgh. Of the 11 deaths attributed to diarrhoea, three occurred in Edinburgh and two each in Glasgow, Aberdeen, and Leith. Four of the six fatal cases of diphtheria were returned in Glasgow; and measles caused two deaths both in Glasgow and in Edinburgh. The deaths in the eight towns referred to diseases of the respiratory organs, including pneumonia, which had been 149 and 155 in the two preceding weeks, declined to 147 in the week under notice, but exceeded the number in the corresponding week of last year by 23. The causes of 18, or 2.5 per cent., of the deaths registered during the week in the eight towns were not certified or not stated; the percentage of uncertified deaths in the 76 English towns during the same week did not exceed 1.1.

The annual rate of mortality in eight of the principal Scotch towns, which had been 20.5 and 20.6 per 1000 in the two preceding weeks, declined again to 20.3 in the week ending March 30th, but exceeded by 2.6 per 1000 the mean rate in the 78 large English towns. The rates in the eight Scotch towns ranged from 15.6 in Leith and 16.1 in Aberdeen to 21.2 in Paisley and in Greenock, and 22.1 in Glasgow. The 706 deaths in the eight towns showed a decrease of nine from the number in the preceding week,

and included 107 which were referred to the principal epidemic diseases, against 100 and 102 in the two preceding weeks. These 107 deaths were equal to an annual rate of 3.1 per 1000, which exceeded by 1.3 per 1000 the rate from the principal epidemic diseases in the 76 English towns; they included 39 which were referred to "fever," 34 to whooping-cough, 19 to diarrhoea, seven to measles, six to diphtheria, and two to scarlet fever, but not any to small-pox. The deaths referred to "fever," which had been 43 and 48 in the two preceding weeks, declined again to 39 last week, and included 31 in Glasgow, four in Edinburgh, three in Paisley, and one in Leith; all these 39 deaths, with the exception of one in Paisley, were certified as cerebro-spinal meningitis. The deaths from whooping-cough, which had been 33 in each of the two preceding weeks, rose last week to 34, of which 26 occurred in Glasgow, three in Edinburgh, and two in Aberdeen. The fatal cases of diarrhoea, which had been 13 and 11 in the two preceding weeks, rose again to 19 last week, and included nine in Glasgow, three in Edinburgh, three in Aberdeen, and two in Paisley. Of the seven deaths from measles, four occurred in Glasgow and two in Edinburgh; and three of the six deaths from diphtheria were registered in Glasgow. The deaths in the eight towns referred to diseases of the respiratory organs, including pneumonia, which had been 155 and 147 in the two preceding weeks, declined to 123 during the week under notice but were 20 in excess of the number in the corresponding week of last year. The causes of 21, or 3 per cent., of the deaths registered during the week in the eight towns were not certified or not stated; the percentage of uncertified deaths in the 76 English towns during the same week did not exceed 0.8.

HEALTH OF DUBLIN.

The annual death-rate in Dublin, which had been equal to 28.6, 25.2, and 24.9 per 1000 in the three preceding weeks, further declined to 22.3 in the week ending March 23rd. During the first 12 weeks of the current quarter the death-rate in the city averaged 27.5 per 1000; the mean rate during the same period did not exceed 19.3 in London and 19.7 in Edinburgh. The 167 deaths of Dublin residents registered during the week under notice showed a further decline of 20 from the numbers in recent weeks, and included 12 which were referred to the principal epidemic diseases, against ten and 16 in the two previous weeks. These 12 deaths were equal to an annual rate of 1.6 per 1000, and included seven from whooping-cough, three from measles, one each from diphtheria and diarrhoea and not one either from scarlet fever, "fever," or small-pox. The fatal cases of whooping-cough exceeded the number in the previous week, while those of measles and diarrhoea showed a decline. Two deaths were also referred to cerebro-spinal fever. The deaths in the city included 27 of infants under one year of age and 35 of persons aged upwards of 60 years, showing a marked decline from the numbers in the previous week. Four deaths from violence and five inquest cases were registered; and 67, or 40.1 per cent., of the deaths registered during the week occurred in public institutions. The causes of all but one of the deaths in the city were duly certified; the percentage of uncertified deaths in the week under notice was 3.5 in Edinburgh and 0.1 in London. The 167 deaths registered in Belfast during the week ending March 23rd included 14 certified as due to cerebro-spinal meningitis or cerebro-spinal fever.

The annual death-rate in Dublin, which had been equal to 25.2, 24.9, and 22.3 per 1000 in the three preceding weeks, rose again to 24.3 per 1000 in the week ending March 30th. During the past quarter the death-rate has averaged 27.2 per 1000, the mean rate during the same period being 19.2 in London and 19.6 in Edinburgh. The 182 deaths of Dublin residents registered during the week under notice showed an increase of 15 over the number in the preceding week; and included 12 which were referred to the principal epidemic diseases, against 16 and 12 in the two preceding weeks. These 12 deaths were equal to an annual rate of 1.6 per 1000, and included four from measles, four from whooping-cough, two from "fever," and one each from diphtheria and diarrhoea, but not any from either small-pox or scarlet fever. The fatal cases of measles slightly exceeded the number in the previous week, while those of whooping-cough showed a decrease. The deaths from all causes included 26 of children under one year of age and 44

of persons aged upwards of 60 years, the latter being nine in excess of the corresponding number in the preceding week. Five deaths from violence and two inquest cases were registered; and 70, or 38.5 per cent., of the deaths registered during the week occurred in public institutions. The causes of three of the deaths were not certified; in London no uncertified death was registered last week and in Edinburgh only one.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointments are notified:—Fleet Surgeons: W. M. Craig to Haslar Hospital; G. A. Waters to the *Excellent*, for the *Revenge*; F. A. Brice to the *President*, for three months' course at West London Hospital; F. J. Lilly to the *President*, for three months' course at Greenwich Hospital; and D'Arcy Harvey to the *Argonaut*, on commissioning. Surgeons: G. M. O. Richards to Haslar Hospital, P. T. Sutcliffe to the *Exmouth*, and W. P. Hingston to the *Vivid*.

ROYAL ARMY MEDICAL CORPS.

Captain Frederick F. Carroll is seconded for service with the Egyptian army (dated March 19th, 1907).

ROYAL ARMY MEDICAL CORPS IN INDIA.

Lieutenant-Colonel J. R. Forrest is appointed to command the Station Hospital at Delhi, vice Major Tibbias transferred. Major J. Hennessy to command the Station Hospital at Poonamallee and Major N. Tyacke to the command of the Station Hospital at Dalhousie. Captain L. W. Harrison is appointed to the medical charge of the Headquarters Staff and Establishments, Northern Command, Murree, vice Captain R. S. H. Fuhr, D.S.O. Lieutenant J. Campbell is appointed to the charge of the 8th Divisional Laboratory. Captain E. B. Knox sailed for England on duty with troops by the hospital ship *Plassy* on March 6th. Captain G. H. J. Brown has passed in lower standard Burmese. Leave out of India to the following officers has been granted: Lieutenant-Colonel F. W. G. Hall, from May 28th to Dec. 28th; Captain E. B. Knox is granted eight months combined leave out of India from March 6th; Major F. McDowell is granted seven months from April 1st to Oct. 31st. Lieutenant-Colonel R. E. Molesworth has been permitted to retire from the service from March 6th. Major M. Boyle has been transferred from Meerut to Bareilly for duty in the station hospital.

VOLUNTEER CORPS.

Rifle: 1st Volunteer Battalion the Royal Sussex Regiment: Alfred Heathcote Copeman to be Surgeon-Lieutenant (dated Feb. 23rd, 1907). 2nd Volunteer Battalion the Royal Sussex Regiment: Surgeon-Captain John Elsdale Molson, from the 2nd Volunteer Battalion the Essex Regiment, to be Surgeon-Captain (dated Feb. 12th, 1907).

ROYAL ARMY MEDICAL CORPS (VOLUNTEERS).

The Sussex and Kent Bearer Company: Lieutenant-Colonel J. Turtan (Brigade-Surgeon Lieutenant-Colonel, Senior Medical Officer, Sussex and Kent Volunteer Infantry Brigade) is granted the honorary rank of Colonel (dated Feb. 18th, 1907).

THE MILITIA SYSTEM.

Lord Wemyss sends us a letter protesting against Mr. Haldane's suggested alterations in our military system which Lord Wemyss thinks has satisfied all Statesmen and soldiers in the past, and is so well suited to our insular position. To substitute a so-called "Territorial Army," the letter continues, resting on nothing but hope, patriotic self-sacrifice, and speculation, will not be acquiesced in by responsible, and the same men who will insist on the Militia being left out of the War Minister's scheme. Our existing military system, Lord Wemyss goes on to say, if put in force, will fully satisfy all our military requirements without increase of cost.

The War Office has approved of the payment of bounties to Militia-men of the Royal Army Medical Corps, of two classes: (a) to those who attend the prescribed training, to be termed training bounty; (b) to those who do not attend the training, to be termed non-training bounty.

DEATHS IN THE SERVICES.

Surgeon-Colonel John McConaghey, I.M.S. (retired), at

residence, Exmouth (Devon), on March 25th, in his fifty-ninth year. The deceased officer, who graduated M.D., Ch. of the Royal University of Ireland in 1871, entered the Bengal department of the Indian Medical Service in March, 1872, and became surgeon-colonel in June, 1902. He retired in 1905 and took up his residence at Exmouth. Deputy Inspector-General W. J. Baird, R.N. (retired), lately, at Brighton. He was assistant surgeon of the *Leander* the Black Sea throughout the Crimean war and was "lent" various ships during the cholera epidemic of 1854; he landed attend to the wounded after the battle of Alma and served in the Naval Brigades at Eupatoria and before Sebastopol (Crimean and Turkish medal, Sebastopol clasp); served with a 1st Battalion of Royal Marines during the Chinese war 57-59 and was acting surgeon of the *Assistance* while used a hospital ship off Canton; present at the attack of the *Aras* near the White Blend Mountains, and at the capture of the bridge and village of Sheek-ling; was landed in medical charge of Marines during the attack on the Peiho forts, specially mentioned in despatches (China medal, *Aras* clasp); surgeon of the *Spitfire* in the West Indies during the epidemic of yellow fever, 1861; served in the *Aras* on the West Coast of Africa throughout the Ashantee war, 1873-74, was present at the destruction of Elmina and several villages on the coast, and medical officer of health at Cape Coast Castle (Ashantee medal).

ARMY SANITATION.

A correspondent writing in the *Times* of April 3rd says: "The statistics of mortality due to disease in the South African war, when compared with the losses more recently suffered by the Japanese from the same causes, demonstrated clearly that in the matter of sanitation there was in the British army considerable room for improvement. It is, therefore, satisfactory to find that the matter has been thoroughly taken in hand by the Army Council and a series of regulations issued, which should bear good fruit in our future campaigns. Under the direction of authority, a manual of sanitation has been prepared the contents of which the combatant officer will not only have to be acquainted with, but will have to submit to have his knowledge therein tested by examination. . . . On the outbreak of war there will be formed for service in the field a committee, consisting of a combatant field officer as president, with a field officer R.E. and a field officer R.A.M.C. as members. This committee will act under the orders of the general officer commanding-in-chief, and its duties will be to ascertain that sanitary appliances and materials of all kinds required for the army are forthcoming, and that an adequate reserve is maintained."

JOURNAL OF THE ROYAL ARMY MEDICAL CORPS.

The March number of this journal is a very good one. We would particularly call attention to the very interesting paper on Recent Researches into the Epidemiology of Malta Fever, by Colonel David Bruce, C.B., F.R.S., which was read before the Epidemiological Society on Feb. 15th last. It is a brief and, at the same time, exhaustive and practical exposition of all that is known in regard to this disease.

Revised regulations regarding the Indian Medical Service have now been issued.

Correspondence.

"And aliam partem."

THE WATER-SUPPLY OF CAIRO.

To the Editors of THE LANCET.

SIR,—My attention has been drawn to a letter in THE LANCET of Jan. 26th, p. 251, over the signature of Mr. John M. Robertson, M.P., which deals in part with the question of the Cairo water-supply and more particularly as regards the quality of the water supplied by the company to the town of Cairo. I much regret I had not the opportunity of meeting the writer during his short visit to this country, as I should have been only too happy to have given him all the information in my power as regards the Cairo water-supply and so have saved him the annoyance of finding he had been misinformed by someone who evidently has no knowledge of the existing state of affairs. The remarks he makes would, to a great extent, have been

correct three or four years ago, at which time the town was supplied with water taken direct from the Nile and filtered through sand filters, when the water was of poor quality as regards purity, especially during low Nile, and as regards clearness during the high Nile.

In 1903 the question of improving the supply was seriously taken in hand and experiments were made with a view to finding a pure source. The borings made by the water company showed that there existed an underground stream, and the tests which were made showed that underground water taken from deep bore holes was of great purity, both chemically and bacteriologically, and since then the whole supply has been remodelled and a completely new pumping station has been erected taking the water from deep bore wells, about 200 feet deep. The water is of exceptional purity and is always clear as crystal on its arrival at the surface. The whole of Cairo's drinking and domestic supply is now pumped from these wells, and Nile water is only used for road-watering and gardens. Even for this purpose the Nile water-supply will, however, be entirely superseded by well water in the course of about 12 months from date, when all the wells are completed. In his letter Mr. Robertson says that in the police schools the drinking water is very carefully filtered. This is possibly the case, but it is quite unnecessary and, as a matter of fact, I understand that the Government officials and experts contend that the water taken direct from the company's mains is so pure that it is only liable to be deteriorated by manipulation, such as filtering or boiling, unless great care is taken as to the cleaning of the vessels employed. Again, not only is the drinking water of the town not "officially recognised to be bad," but the water now being supplied has been officially accepted by the Government as of pure and excellent quality for domestic purposes. This can easily be proved by applying to the authorities. Again, it is not discoloured at high Nile, but is of the same clearness all the year round.

As you will see from the above statements, which can be verified by application to the local authorities, his letter gives quite a false impression of the existing state of the Cairo water-supply, and in fairness to my company I shall be much obliged if you will publish this letter in THE LANCET at the first opportunity.

I am, Sirs, yours faithfully,

ASTLEY P. FRIEND,
Manager, Cairo Water Company.

Cairo, March 21st, 1907.

GRADUATED LABOUR IN SANATORIUMS.

To the Editors of THE LANCET.

SIRS.—Naturally enough, when one reads remarks by Dr. T. D. Lister and Mr. O. H. Garland and Dr. M. S. Paterson,¹ one pays respectful attention to the conclusions come to by those well qualified to judge as to what really is the best thing to be done for the working-class consumptive. Recent work has been useful especially in clearing the subject of after-treatment of those preconceptions which had led to what Sir R. Douglas Powell calls "airy and unpractical advice." But one sees in one or two appreciations of such inquiries a certain note of enthusiasm as to the heavy nature of "the work which may be expected of public sanatorium patients, and with such beneficial results, according to these authors, that it seems a natural inference that the better off should surely be given a chance of participation as well. For it is, of course, a fact that at nearly all private sanatoriums anything in the nature of hard exercise is forbidden even for the most robust patients.

Now let me from experience gained by residence in two public and four private sanatoriums try to point out a reason or two why it is likely that the teaching of the latter as to exercise is the correct one so far as absolute therapeutic value goes. I think that they should give pause to the enthusiasms just noticed. In the first place, if the private patient is forbidden violent exercise it is with no idea of pleasing him, for the average upper middle-class patient, whether male or female, often wishes nothing so much as to continue some favourite game or sport. When he leaves—and his state then if his condition has allowed walking exercise is by no means "soft"—he often breaks rules as to exercise laid down for him and, as many sanatorium physicians seem to think, has to return as a more or less direct consequence of this, and I cannot

¹ THE LANCET, March 9th (p. 577) and 23rd (p. 525), 1907.

suppose that the suddenness of indulgence in unaccustomed exercise is the main factor in the breakdown. One has seen made the most cautious and persevering attempts to resume some favourite exercise with quite unsatisfactory results. Then there is this point, that the private sanatorium physician has a much harder therapeutic task and gains thereby a more detailed insight into treatment. If a man comes to one because he is not getting on as quickly as he would like (and the laity have remarkably exacting views as to this) in a hut in his grounds, it is very obviously more difficult to improve his condition than it is that of an artisan from the town. Couple with this the fact that it is very hard to judge of the effect of the treatment in phthisis, especially in improving cases. If a patient gets on well while digging unbroken ground it by no means follows that he would not do better with gentle uphill walking. Let us not forget the natural intermissions of the disease or the fact that the test of an alternation of current types of treatment is one which is never deliberately applied and which only occurs occasionally and by chance. The few instances of it which I have seen have not left me with much opinion of the absolute therapeutic value of the plan of working the consumptive sound. And as to the advisability of treating patients to the best advantage, let German statistics as to final results speak. Finally, the traditions of treatment are at private sanatoriums much longer; their physicians have fewer patients and can study them more closely, the patients themselves stop longer, and return (if they need to) much more frequently for further treatment. Opportunities of observation are therefore, on the whole, much greater, for two cases observed thoroughly and at length teach one more than a rapid succession of 20. If, then, with these advantages for judging private sanatoriums pronounce against hard exercise, is it wise to be enthusiastic over physical feats by consumptives, especially if one remember the poor physique they often show?

Now, in saying all this one does not wish in the least to ram one's conclusions down anyone's throat. It is easy enough to see that under our present unfortunate social conditions the great thing is to procure the main essentials of the treatment for as many as possible of the consumptive proletariat and to prolong the working life of each as much as one can. In presence of these two objects, especially of the latter, minor therapeutic details must go by the board. But in the hard task of striking the balance of considerations one will not be at all helped (to avoid the serious errors which beset one) by the state of lay opinion likely to be promoted by sentimental preconceptions which look on the treatment of early phthisis in the working classes as muscle culture plus straight talks against loafing. If such enthusiasms be not checked, sanatorium treatment of the working man may come for a time to suffer somewhat as (with due apologies to Professor Armstrong and the Heuristic method) primary education did at Dotheboys Hall.

I am, Sirs, yours faithfully,

W. C. RIVERS.

Crossley Sanatorium, Frodsham, March 23rd, 1907.

•IDIOPATHIC (MICROBIC) CYANOSIS.

To the Editors of THE LANCET.

SIRS,—Under ordinary circumstances the letter published in your issue of March 9th of Dr. Samuel West and Dr. T. Wood Clarke would not call for any notice, but as my friend Dr. Carstairs G. Douglas has made a real addition to our knowledge it would be unjust to him to pass by any attempt to belittle its value without protest. Put briefly, as the result of a long series of chemical and bacteriological observations on the patient whose case was fully described in our paper, Dr. Douglas found that the blood revealed the presence of methæmoglobin; that the blood, saliva, and feces contained nitrites; that the feces had no power of converting ox blood into methæmoglobin; that these facts raised the suspicion of a hæmatogenous formation of methæmoglobin; and that very careful investigations proved that the blood contained the bacillus coli or a very closely allied organism. With these results, as far as one case can go, we are absolutely satisfied. One positive observation is of more value than countless negative statements. We, desire, however, to obtain further opportunities of research in other patients. In this hope we made the statement: "It seems to us very desirable that these observations should not

be taken as final and if opportunity presents itself it will be repeated, especially those of a bacteriological nature." Surely Dr. West and Dr. Clarke are able to appreciate the difference between a desire for further observations on a more extended series of cases and a doubt the correctness of our results! In making this remark there is no intention to impugn the good faith of your correspondents. They simply appear to be victims of a tendency towards "terminological inexactitude." That this is probable the state of their minds may be gathered from the fact that in spite of their perusal of the Dutch literature on the subject, in which, with an imitation which may be regarded as the sincerest flattery, they have faithfully followed in the footsteps, they nevertheless make the statement that "suggest the term 'microbic cyanosis' to take the place of methæmoglobinæmia." We disclaim this intention inasmuch as methæmoglobinæmia is only one form of that complex known as cyanosis—true and false. The term idiopathic cyanosis, it may be added, is bad, not only because the word idiopathic is archaic, but because it has been applied to polycythæmia with splenomegaly, which has recently been thoroughly discussed.

In conclusion, let me add that although the remarks made by Dr. West and Dr. Clarke on the careful observations of Dr. Douglas certainly require correction, it was a matter of interest to me that a case of sulph-hæmoglobinæmia had been observed in this country. It is to be hoped that the authors will have further opportunities of investigating the condition so that they may be able to add something to the observations of Dr. A. A. Hijmans van der Bergh and Meijer-vro Gutterink.

I am, Sirs, yours faithfully,

Edinburgh, March 26th, 1907.

G. A. GIBSON.

* * We have retained the term "idiopathic" in the heading because former letters on the subject have borne this title—ED. L.

THE USE OF ALCOHOLIC BEVERAGES

To the Editors of THE LANCET.

SIRS,—It is difficult to fathom the objects of the prominent clamour on the alcohol question, which appears in your columns under this title, signed by 16 eminent members of the medical profession. It may be that they consider themselves the oracles of the medical profession whose opinion should be received with unreasoning credulity by the brethren. It may be very gratifying to each of them to say "I am Sir Oracle, and, when I open my lips, let no dog bark!" On the other hand, it may be that they just wish to let the public know that they are still alive and have not succumbed to the baneful influence of alcohol. Whatever the motive force I should like to remind them that we are now in the twentieth century and oracular statements are no value whatever. If their "statement represents the opinion of the leading clinical teachers as well as of the great majority of medical practitioners," then the necessity for their manifesto does not exist and it becomes a most blatant advertisement. If, on the other hand, it be the zeal for the public weal which forces them into print, surely it is their duty to let the medical profession and the public know the reasons for the faith which is in them. If they have got one scintilla of evidence in support of their statements by all means let us have it. I am pleased to say that I know the majority of the signatories (I have nothing to say against their temperance), and I know most of their writings, but I do not know one of them who has ever done any experimental work of any value either on the use or abuse of alcohol. It is true that Mr. Jonathan Hutchinson has shown that it is an excellent mouth wash in cases of operation on the tongue, but he did not produce any comparative evidence as to whether it was better or worse than many other antiseptic mouth washes.

In many cases it may be truly described as life preserving, owing to its power to sustain cardiac and nervous energy, while protecting the wasting nitrogenous tissue. Surely we are here on safe ground. I can scarcely think that 16 eminent men would make such a statement unless they knew what they were talking about. I have written on Alcoholic Asthenia and on the Therapeutic Uses of Alcohol, and I am extremely anxious to get reliable information as to its power to sustain cardiac and nervous energy. It won't do to tell me that they have seen severe cases of typhoid fever or pneumonia cured by brandy, because many

such cases get well in spite of treatment. I want some experimental evidence to prove this supposed tonic effect on the heart and nervous system. Among the signatories are no pharmacologists and one physiologist, and they ought to be able to settle this vexed question; for one of them it ought to be as simple to settle the physiological action of alcohol as of adrenalin.

I take a little alcohol myself when I have nothing better to do, because I like it, and I prescribe it as a sedative, an antispasmodic, and to paralyse the vaso-motor system, much in the same way as I order nitroglycerine. As a matter of fact, I have had two glasses of champagne while writing his letter in order to mollify my opinion of this pernicious manifesto which I candidly think savours strongly—not of champagne but—of impertinence in presuming to dictate to the medical profession as to the value of alcohol. To-day some shrewd business men asked, How many cases of Scotch whisky did this manifesto represent? I resented the suggestion, but the signatories have only got themselves to thank if the public put a commercial value on their document.

I am, Sirs, yours faithfully,
JAMES BARR.
Liverpool, March 30th, 1907.

To the Editors of THE LANCET.

SIRS,—The manifesto on the subject of alcohol published in your columns is gratifying in one sense, because it seems to show that temperance views are becoming so prevalent that a counterblast is thought to be necessary. But it is difficult to imagine what good it will do, or why medical men should thus champion the liquor interest. The first part of the statement is not a matter of much concern to the temperance party. It refers exclusively to the use of alcohol as a remedy in disease. Now, alcohol may be all that they say it is, and a great deal more, and yet be most undesirable as a daily beverage. In fact, the more powerful it is as a drug the more it should be avoided as an article of diet. On the other hand, the less one is accustomed to it the greater effect it will have when (if ever) it is required.

Those who have had the desire, the courage, and the opportunity to put the non-alcoholic treatment of disease to a sufficient test have, without known exception, been astonished at the success they have experienced. The results at the London Temperance Hospital, showing a mortality lower than that of most other general hospitals, would be impossible if alcohol were so necessary as the manifesto seems to imply. We maintain that whatever benefit can be derived from alcohol can be obtained by other methods or other drugs without the disadvantages which often accompany its use. Such a powerful drug as they allege it to be must necessarily be powerful for evil in certain cases, if for good in others. It has probably destroyed far more lives than it has saved. But if it is to be used as a drug it should be dispensed as such, in a pure form, in an exact dose for a definite time, and, if possible, without the patient's knowledge. Given thus it would do far less harm than it does now as usually prescribed, and temperance reformers would no more object to it than they do to the medicinal use of opium or arsenic.

But, leaving this side of the question, which is really a matter for medical discussion only, there is very little to worry about. We are only favoured with a statement that these gentlemen believe "that the universal belief of civilised mankind that the moderate use of alcoholic beverages is for adults usually beneficial is amply justified." As a matter of fact this belief is not universal, since millions believe alcohol to be injurious. Again, the belief of other millions that it is beneficial does not prove it to be so. For the great majority of those who take it take a good deal more than these gentlemen would admit to be "a moderate quantity" and yet believe that it does them good. They do not tell us what is the limit of moderate use. "Belief of benefit" would justify opium smoking, opium eating, and other harmful indulgences, with regard to which we may presume that all these gentlemen are total abstainers. These habits can only be justified by their results, and more evidence can be produced of the evil results of acquiring the alcohol habit (which is almost without exception "moderate" at first) than any newspaper would care to print. The matter has really been settled by the experience of those life assurance societies which insure abstainers and non-abstainers in separate departments. All such have found that the use of alcohol shortens the average duration of life. In the largest of these offices the experience covers about 40 years, has been of the same character

every year, and shows that of every 100 expected deaths of non-abstainers about 97 occur, while of every 100 of abstainers only 72 occur. If it had been the other way round we might have listened respectfully to the dicta of these leaders of the medical profession, but in the circumstances we think otherwise and consider ourselves amply justified in avoiding so potent a cause of disease and death. One wonders where the benefit comes in, for wherever any fair comparison of large bodies of men has been possible, whether as to health, work, endurance, or vitality, the advantage has been on the side of the abstainer. The evidence of the feelings is no criterion whatever, as the judgment is perverted. Any nation will be healthier, wealthier, and wiser by total abstinence and prohibition. Not that all will be on the same level, any more than in the case of individuals, because there are many other things affecting the result. At any rate, no sane doctor will assert that alcohol is necessary for healthy persons; being superfluous such a drug is not likely to be harmless.—I am, Sirs, yours faithfully,

J. J. RIDGE,
Honorary Secretary, British Medical Temperance Association.
Barnfield, March 30th, 1907.

To the Editors of THE LANCET.

SIRS,—It is with much gratification that I have read the courageous manifesto on the above subject in your last issue—courageous, because the profession appears to have been hypnotised into silence of late years by the temperance enthusiasts and to have lacked the courage to express publicly its views on the alcohol question. Very properly you point out the enormous importance to the profession and public alike of this epoch-making confession of faith on the part of a distinguished and representative body of scientists. The teetotal enthusiasts have held the field too long unchallenged by the acknowledged leaders of the profession and we may well hope that at last prejudice will have to give place to dispassionate and unprejudiced inquiry into the real facts of the case. Possibly under the influence of this sadly needed stimulant the profession will now shake off its lethargy and take some steps to repair the damage that it must always sustain in the eyes of the public when it leaves the apparent settlement of subjects of so great importance as that under consideration to the generally more pushful and enthusiastic minority.

I am, Sirs, yours faithfully,
A. H. COPEMAN, M.D. Dub., &c.
Brighton, March 30th, 1907.

To the Editors of THE LANCET.

SIRS,—Everyone must recognise the high standing in their profession of the gentlemen who sign the manifesto in favour of alcohol. The question of its therapeutic value is after all one which must be decided by medical men themselves, and doubtless there is a large number of the profession who hold that alcohol has such a value. The manifesto is so loosely worded that it does not appear on the face of it whether it is alcohol as a drug pure and simple to be administered by medical men and in the ordinary form of medicine that is intended or whether it is the prescription of ordinary alcoholic liquors that is recommended. If it is the latter the first thing that should be done is to fix some standard of quality. As a chemist I know the extremely various constituents of the different alcoholic liquors in common use and to give a general recommendation, such as that which appears over the names of these gentlemen, seems to me to be a departure from those accurate preparations of medicine which one imagines takes place in the dispensing room. No one can object to the medical man using alcohol in the preparation of a medicine just as he might use strychnine or opium, but everyone can very properly object to the medical man telling his patient to go to the wine merchant or the public house for his physic. The fact that alcohol may be of value in the abnormal conditions of the sick body does not in the least degree show that it has any value to the healthy body. The opinion is expressed that the majority of men can use alcoholic liquors in moderate quantity without harm. The manifesto would have been more convincing if something in the shape of data had been given in support of the opinion. Why not bring forward new information controverting the experience of the life assurance societies? Why not show that the marvellous decrease in the consumption of alcohol in the general hospitals and infirmaries during the past 30

years has been a mistake? Why not bring evidence to show that the alcoholic patient is a better one than the non-alcoholic? And why not give a scientific definition of what is meant by the abuse of alcohol?

I am, Sirs, yours faithfully,

April 2nd, 1907.

WALTER N. EDWARDS.

To the Editors of THE LANCET.

SIRS,—I observe that in THE LANCET of to-day's date a statement on alcohol is published to which my name has been attached without an addition which I had made a necessary condition to this being done.

The addition is that of the word *many* before the word "adults" in the second last paragraph, a paragraph which deals with the use of alcohol as an article of diet, as distinguished from its use as a therapeutic agent. I am informed that this word was actually inserted in the proof before authority was given to add my name to the statement.

The condition of my consent was therefore that the part of the paragraph referred to should read, "..... the moderate use of alcoholic beverages is, for '*many*' adults, usually beneficial," &c. I am, Sirs, yours faithfully,

Edinburgh, March 30th, 1907.

THOMAS R. FRASER.

* * The error was not made by us.—ED. L.

THE TRANSMISSION OF PLAGUE.

To the Editors of THE LANCET.

SIRS,—The report in the *Journal of Hygiene* from the Plague Commission in India has established very conclusively the fact that the flea is the most important factor in the transmission of plague from rat to man. This report confirms the theory first formulated by Simond and afterwards further elaborated and demonstrated by Elkington, Thompson, and Tidswell. Elkington's paper, published in the *Australasian Medical Gazette* for August, 1903, can be said to have first scientifically shown the transmission of plague from rat to rat by means of the flea. The reports on the Sydney outbreaks 1900-1904 are valuable records of a systematic research by epidemiological methods into the etiology of plague and constitute a most valuable collection of data in connexion with the disease. Elkington's paper and the Sydney reports can claim to have scientifically proved the connexion of rats and fleas with the recurrence of plague in man, and we think that these workers have not received that recognition that their results deserve.

Our object in writing this letter is to show that the splendid opportunity of studying outbreaks of plague on a large scale in a European community has not been lost and that scientific work of a high character in connexion with the disease has been carried out in Australia. We would also like to point out that while imperial honours, as is only right, have frequently been conferred on the medical officers of the various smaller colonies, those of the great self-governing States have hitherto been almost entirely ignored, though much valuable work, often of world-wide importance, has been done by such officers.

In conclusion, it is hardly necessary for us to say that, working as we do in a far-distant part of the Australian Commonwealth, we have no direct connexion with the three investigators above mentioned, though profiting much by their researches, and as a natural delicacy has prevented them from laying claim to the credit which is their due, we who are able to estimate the merit of their work have considered it right to take this opportunity of making it known.

We remain, Sirs, yours faithfully,

T. L. ANDERSON, M.D. Melb.,

Special Medical Officer, Fremantle, W.A.

J. BURTON OLELAND, M.D. Syd.,

Government Pathologist, Perth, W.A.

Public Health Department, Central Board of Health,
Perth, W.A., Feb. 23rd, 1907.

THE PRODUCTION OF THE HOT CROSS BUN.

To the Editors of THE LANCET.

SIRS,—Attention has been called in the lay press this Easter tide to the conditions of production of hot cross buns. One's first inclination is to attribute the outcry to the requirements of journalism during recess, but there can be

no doubt that there is serious reason for the protests which have appeared. I have been told by an absolutely reliable and highly expert authority that in 80 per cent. of bake houses the additional work entailed is well nigh intolerable. The custom of the trade is on the Wednesday in Holy Week to work all night baking bread for Thursday and Friday and then, without rest, to begin making the hot cross buns for Friday. This is done, of course, in batches, each batch requiring the nicest attention and close watching. The temperature of the bakehouses averages 90° F. and the atmosphere is rendered additionally trying by the steam from the buns and the fumes of the furnace ash. Often the bakers work from 30 to 36 hours without sleep immediately after the extra bread-making entailed by Good Friday, and it is no unusual thing for the men to drop off to sleep whilst at work, in spite of every effort to keep awake. During this period, too, the shop assistants have to be on duty to remove the buns from the baking sheets, to store them in the shop or place them in bags for delivery, but of course this duty cannot be compared to the strenuous work of the bakehouse. It requires little imagination to foresee the state of exhaustion of the regular and journeyman baker when Good Friday arrives, after so many hours of labour at such a temperature, labour, too, demanding the most unremitting care and almost the master-touch. Though Cross has replaced Crescent the hot cross bun is the direct descendant of the cakes offered to the Queen of Heaven and comes originally from the Phœnician worship of Astoreth. Still, that is no reason why in the twentieth century we should encourage our good friends the bakers, even voluntarily, "to pass their sons through the fire" to the Moloch of fashion.—I am, Sirs, yours faithfully,

J. ALISON GLOVER, M.D. Cantab., D.P.H.

Highbury, March 31st, 1907.

THE UNIVERSITY OF LONDON SENATORIAL ELECTION.

To the Editors of THE LANCET.

SIRS,—I must take exception to the hysterical heading of Dr. E. H. Starling's letter in the *British Medical Journal* of March 30th. There is no "threatened disintegration of the University of London" but there is a strong desire on the part of many of its graduates that the radical changes initiated since its reconstitution should cease in order that its high position, obtained by a steady process of evolution during a long term of years, may not be lost. It is to give these graduates an opportunity of expressing their desire I have consented to nomination for the vacancy on the Senate in May next. We recognise in Sir Thomas Barlow one of the parents of the concentration scheme at South Kensington, which now stands condemned by the vote of the Medical Faculty on March 19th, when Dr. H. A. Caley and Dr. L. E. Hill defeated Dr. J. R. Bradford and Dr. J. K. Fowler, the former representatives on the Senate. Dr. Starling states, "The suggestion as to the lowering of the standard of the degrees is devoid of foundation." How does he reconcile this statement with the following official statistics? At the intermediate medical examinations for the quinquennial period 1892 to 1896 45.2 per cent. of the candidates were rejected; from 1897 to 1901 40 per cent.; and from 1902 to 1906 30 per cent. At the 1906 examinations only 27.2 per cent. failed to pass. Then, again, at the M.D. examinations. In 1906 only eight candidates in 60 failed and in December, 1905, but three in 20 were rejected, whereas in July of that year 12 failed out of 31. In July, 1906, 14 presented themselves in medicine and 13 passed, and last December 17 entered and 15 passed. In midwifery and diseases of women six presented themselves in December, 1906, and five passed; and in July of that year 11 entered and ten passed.

I am, Sirs, yours faithfully,

London, April 1st, 1907. ERNEST W. WHITE.

THE ALLEGED INCREASE OF INSANITY

To the Editors of THE LANCET.

SIRS,—In Dr. G. H. Savage's Lumleian lecture which is published in THE LANCET of March 30th, p. 855, it is stated in connexion with the subject of general paralysis of the insane: "In the last report general paralysis is stated to be increasing more rapidly in Edinburgh than in Glasgow. This seems hard to explain, but I am inclined to think that more careful clinical examination in Edinburgh may account

for the fact." Dr. Savage is, of course, quite entitled to think as he pleases, but when he puts his thought into speech or print and throws what is apparently a slur on the methods of clinical examination in Glasgow he should give reasons to show what has led to his belief. Is it not the fact that the recognition of general paralysis is more difficult than at first sight appears? that, in other words, more careful clinical examination is required to say what is not general paralysis than what is? Is Dr. Savage prepared to point out any pathognomonic sign of general paralysis? Does he believe that the bacillus paralyticus of Ford-Robertson is the cause of the disease and the presence of that organism pathognomonic?

As one who has taken a great practical interest in the study of this particular question, I still am of opinion that there is no pathognomonic sign of general paralysis of the insane and that it is a disease which is often liable to be confounded with cases of cerebral syphilis, saturnine poisoning, psychasthenic, alcoholic, and other forms of the insanities. In this particular asylum, which is the largest in Scotland, and one of the number serving Glasgow district, the method of examining all newly admitted cases is such that no patient is allowed out of bed until an accurate report of his bodily and mental condition has been made. When the admitting physician is in any difficulty it is invariably the custom for him to consult with the other medical officers, all of whom have had varied experience in general hospitals before they became asylum physicians. I will be glad to hear through you on what grounds, if any, Dr. Savage has based his belief regarding the inferior clinical methods pursued at Glasgow as compared with Edinburgh.

I am, Sirs, yours faithfully,

HAMILTON C. MARR.

Medical Superintendent, Glasgow District Asylum,
March 30th, 1907. Woodlee, Leith.

THE BIRMINGHAM GENERAL HOSPITAL.

To the Editors of THE LANCET.

SIRS,—Your Birmingham correspondent has either been misinformed or has expressed himself in a misleading manner when he writes that at the General Hospital "steps are being taken to form a plan for the treatment of the more simple cases as dispensary or club patients," which might be taken to mean that the hospital is contemplating the establishment of a dependent dispensary or club. No such proposal has been made but a report of a committee is under consideration which proposes to get rid of that class of patient which can be adequately treated by existing dispensaries or clubs, after rendering these applicants merely such first aid as may be urgently required. I am sending you a marked copy of the *Birmingham Daily Post*, which contains the speech of the chairman of the board upon which, presumably, your correspondent founded his remarks.

I am, Sirs, yours faithfully,

ROBERT SAUNDY.

March 25th, 1907.

THE POLLUTION OF WATER-COURSES.

To the Editors of THE LANCET.

SIRS,—Some of your readers may be able to advise me in the following circumstances. I am resident on my own property on the banks of the river Blackwater, more than one mile below the town of Witham, Essex. This town has recently provided for itself a new water-supply, a new railway station is in course of erection, numerous houses are being built, and, though our rates vie with those of Poplar, the beautiful surrounding country renders it a desirable place of residence. A system of sewerage, with an adequate farm, seems to be efficiently worked; but in the town itself is a hell-mongery with a number of tanks, in which hides and animals' feet are soaked with lime. The contents of these tanks are discharged by simply lifting a sluice every week into the Braintree stream, an affluent of the Blackwater. Two larger tanks are discharged at night, for very obvious reasons. This mass of unspeakable filth passes through a portion of the town, carrying with it quantities of fish, dead and dying. Even at my property the smell is at times abominable; and the agitation of the water in any way produces a mass of seething foam like soap-suds. As the owner of one mile of river bank I have always been ready to permit the free use of it by anglers, who a few years ago called it the best piece of

roach fishing in England; but as I write numerous fine fish lie dead near my garden, and the anglers' occupation will soon be gone.

I have seen pedestrians drink from the river in front of my house, so clear is it at times, and yet the Witham folks wonder why they have cases of diphtheria in the town and why there have been outbreaks of typhoid fever.

I am, Sirs, yours faithfully,

G. W. GRAHAM, M.D. Lond., M.R.C.P. Lond.

Witham, Essex, March 30th, 1907.

THE RIDEAL-WALKER COEFFICIENT.

To the Editors of THE LANCET.

SIRS,—We ask a few lines of your space to state that it has been found necessary to substitute the term "Rideal-Walker Coefficient" for that originally introduced by us—viz., "Carboic Acid Coefficient."

The necessity for adhering strictly to the *modus operandi* prescribed in our test has been strongly emphasised in the last two or three years since we published our method, and that this caution is necessary is shown by the fact that many disinfectants are advertised as having a certain "carboic acid coefficient" when the figure given has obviously been obtained by methods having little or nothing in common with the test as described in the journal of the Royal Sanitary Institute,¹ thus introducing confusion and robbing the term of the value it originally possessed. Much of the success of our method is due to the fact that we provide for the postulant and control being tested not only at the same time but at the same time. As the resistance of the test organism, even when subcultured from the same stock, varies from day to day it is unfair and misleading to offer a "coefficient" obtained by testing the postulant on one occasion and the phenol control on another. Similarly, when the "thread," "garnet," or any modification of the Rideal-Walker test has been employed information that such a method has been used should accompany the "coefficient" and the latter should certainly never be advertised without this information.

It is therefore most desirable that bacteriologists when reporting on the germicidal value of a disinfectant should specify precisely the method employed. Great discredit has been thrown on the Rideal-Walker test by the publication of results obtained by the worker modifying the technique—sometimes to a very large extent—without notifying the modification, and many of the discrepancies referred to by critics are directly attributable to this fact.

We are, Sirs, yours faithfully,

SAMUEL RIDEAL,

J. T. AINSLIE WALKER.

April 2nd, 1907.

MEDICAL TREATMENT OF SCHOOL CHILDREN.

To the Editors of THE LANCET.

SIRS,—Mr. R. W. Rea has introduced into Parliament a Bill "to make provision for vacation schools and for the medical inspection and treatment of school children." This Bill has passed its second reading and was referred to the Standing Committee on Trade. There it was said that "existing organisations, whether philanthropic or charitable, should be made use of as far as possible and thus save the ratepayers' pockets." It was pointed out (*à propos* to the organisation of games) that in the London schools alone there were 2600 departments, that a responsible person could hardly be paid less than £100 a year, and thus an expense of £250,000 a year would be incurred; a clause was therefore added to the effect that the local education authority may encourage and assist voluntary agencies and associate with itself their representatives. The Government itself has introduced a Bill which contains practically Mr. Rea's Bill with the added clause. The Bills, therefore, include medical treatment. Mr. Jowett, M.P., would go further and wishes that the children should not only be treated but cured. He asked the Minister for Education what machinery by inspection or otherwise there was to be for insuring efficiency in the medical measures carried out; Mr. McKenna replied that the matter was receiving his careful attention; it would be well if it also received the careful attention of the medical profession.

When a charitable organisation is used to save the pockets

of the ratepayers the ratepayers become the objects of the charity; many ratepayers are rich people who have no wish to be the objects of charity; others, again, are corporations. In matters medical the voluntary organisations are the voluntary hospitals; at present the objects of their charity are not the ratepayers but the sick poor. The passing of these Bills might, however, legalise or enforce the change. The association of the education committees with the voluntary hospitals may so reduce the income of the profession as to injure not only it but the public for whom it exists. In your columns last week was an advertisement by an ophthalmic hospital for a refraction assistant. He is to be paid £25 a year and his lunch for two mornings a week. If we assume that the work will take three-quarters of his day and allow £15 for the annual value of lunch the whole time of a refraction assistant is worth £115 a year; the governors of the hospital might possibly say that they are not underpaying our profession because the remuneration is only intended as an honorarium, the real reward being the experience which will enable the assistant in a year or so to earn guineas in private practice; but the elementary schools are open to all classes of the community and in fact contain 96 per cent. of the children; thus the remaining 4 per cent. are to maintain the refractionists which one hospital alone is to turn out at the rate of three a year; moreover, if the assistant is only to hold his post till he has learnt his work 96 per cent. of the children will be treated by an imperfectly trained practitioner and there will be much need for Mr. Jowett's inspection. If the assistance education committees give to voluntary hospitals is to be of a pecuniary character in many cases a contract will be made, but with hospitals which already charge out-patients it will only be necessary to send round a batch of children in charge of a teacher provided with the proper amount of pence. If, in addition to refraction, throat, ear, and tubercle assistants are appointed, and to find and sort the defective children there be appointed a lady school medical officer, at a salary for her whole time of, as has been proposed, £100 a year, without lunch, without annual increments, and without pension, then the income of the profession will be reduced and very possibly its usefulness curtailed.

Sir John Gorat in his "Children of the Nation" says: "Every municipality has under the Public Health Acts, as the sanitary authority, the most ample and unrestricted power to provide hospitals for the sick, for the use of the inhabitants of their district. They can either build them or rent them or enter into a contract with the managers of an existing hospital to pay for patients sent by the municipality." If this is so all that is necessary is to empower the Central Government to compel unwilling local authorities to exercise their dormant powers. It is said that this Government Bill contains only non-contentious clauses; so far as medical inspection is concerned this may be correct; the subject has already been inquired into by a committee and no wide differences of opinion brought to light; but with respect to medical treatment at the cost of the rates or by a private practitioner or by a voluntary hospital the clause is only non-contentious because its purport is not realised; the Committee on Medical Inspection just referred to very properly abstained from expressing any opinion on medical treatment; the Minister responsible says he does not know what the cost would be; no one knows that the cost would not exceed the highest possible yield of the rates. Further, the principle of the clause threatens the independent existence of the medical profession and is based on a socialism that has yet to be shown to be workable. The best course, as it seems to me, would be to pass medical inspection and to refer medical treatment to a Royal Commission.

I am, Sirs, yours faithfully,
J. S.

March 27th, 1907.

MEDICAL PRACTITIONERS AND THE MIDWIVES ACT.—At a meeting of medical practitioners of Deptford, Greenwich, and Charlton, held at the Parochial Hall, East Greenwich, on March 28th, it was unanimously resolved that in the event of assistance being required by a midwife under the recent Act, the nearest available practitioner ought to be called, and that the fee should be paid by the guardians on a joint certificate, signed by the medical man and the midwife, stating the reasons why such assistance was necessary. It was further resolved that copies of this resolution should be sent to the guardians and Mr. Hamilton Benn and Lord Alexander Thynne.

THE DISPENSARY QUESTION AT COVENTRY.

(FROM A CORRESPONDENT.)

COVENTRY Provident Dispensary and its relations with the medical staff of the institution is not a new subject in the professional journals¹; but now that within the past fortnight the resignations of five out of the seven medical men have been accepted a new turn has been given to affairs; and seeing that the lay committee must at once endeavour to fill the vacancies which will actually exist in June the profession in general will watch with curiosity whether the committee is successful in its efforts.

It is some dozen years since public attention began to be called to the conditions under which the Coventry Dispensary was conducted and from time to time some small reforms were carried out, under pressure from the medical staff, acted upon by professional men outside. In April last year the Coventry division of the British Medical Association passed a resolution deprecating connexion with any provident dispensary managed on lines fundamentally different to those laid down by the Association, and following on this action the dispensary staff addressed a letter to the committee asking for large alterations—a wage-limit for membership; every medical man in the district to be allowed to act for the dispensary; and the committee of management to consist of the whole staff, the chairman of the Coventry division of the British Medical Association, and an equal number of lay members. There were also requirements as to disposal of income and the collection of weekly payments of members. Briefly, it was proposed to make fundamental changes in the administration and such as would give the profession a controlling power. The committee expressed its willingness to meet the staff on some points, but the concessions were "so valueless," wrote Dr. W. J. Pickup, Dr. T. A. Hird, Dr. W. W. Fenton, and Mr. W. E. Heal, "that it is impossible for us to accept them." These concessions were not to become operative till the dispensary was removed from the professional "black list."

On March 9th Dr. Pickup, Dr. Hird, Dr. Fenton, Mr. Heal, and Mr. A. J. Arch tendered their resignations, leaving Mr. D. I. McVeagh and Dr. J. A. London in office without their positions being respectively disturbed. On the 21st the committee called the members of the dispensary together and St. Mary's Hall was crowded. A long statement, prepared by the committee, was read and it was stated that in the three years ending March of last year Dr. Pickup received a total of £1653 from the dispensary by way of fees; Dr. Hird, £2435; Dr. Fenton, £1322; and Mr. Heal, £853. The great difficulty in bringing about an amicable settlement (the committee further stated) was the uncertainty as to proposals being regarded as likely to last for any length of time. They could not yield upon the points in dispute without sacrificing the independence of the institution and giving away the interests of the members. One of the demands of the medical men was that they should have the right to sell their dispensary practices. The committee says that there is nothing in the fundamental principles of the British Medical Association to warrant this demand. The answer made on behalf of the five medical men to the point is that the Association rules governing contract work simply relate to the lines upon which medical men should conduct these practices. Such practices are their own to do what they like with them and there was, therefore, no need for rules to be drawn up that they should nominate their successors or sell their practices. But the claim of the dispensary committee was that the practices were not the medical men's but the committee's, and the latter claimed the right to give the medical men three months' notice and give other men the practices. The staff say they have an asset in the practices, for one reason because they have to make sacrifices in working them—e.g., they cannot carry on private clubs nor hold any other public appointments.

So the dispute remains, and in accordance with the tenor of the resolution passed at the meeting the medical staff's resignations have been accepted. Matters will probably rest much as they now are for another few weeks, during which Dr. Pickup, Dr. Hird, Dr. Fenton, Mr. Heal, and Mr. Arch will decide in what form they will

¹ Vide THE LANCET, June 12th (p. 1637) and 19th (p. 1703), 1897, and Nov. 4th (p. 1250), 1899.

continue contract practice and the dispensary committee will be making efforts to fill the impending vacancies, though whether it will need five new men is doubtful, for if the seceding medical men carry with them any large number of present patients the future dispensary staff will not need to consist of as many medical men as it has hitherto. There will still be a medical service under some or all of the five practitioners in one form or another. It will be remembered that one of the recommendations of the Medico-Political Committee's report of July, 1905, was that contract practice should be in the hands of some organised local body representative of the profession; that it should be open to every practitioner in the district to take part in the work should he desire to do so and conform to the regulations of the profession; that the details of administration should be under the direct control of a purely medical committee representing both those that do and those that do not take part in contract work. It is also insisted in the report "that to render professional co-operation as complete as possible the divisions should endeavour to secure the inclusion of every practitioner in their membership."

While there is already a public medical service in Coventry—started several years ago, when dispensary matters were then being acutely discussed—it is the intention of the medical men who are leaving the dispensary to set up a service of their own. It is also understood that the rules under which the work is to be carried on will be submitted to the Coventry division of the British Medical Association, but if does not seem to be contemplated either to form one service "open to every practitioner in the district to take part in the work" or to place the control in the hands of any local body representative of the profession. It is worth while to mention that there are already in Coventry three or four private medical clubs, and the new service will apparently be an extension of this form of contract practice.

The general conditions under which the seceding medical staff will work after leaving the dispensary have been made known in a joint circular which has been issued to those members of the dispensary whom these particular members of the medical staff have been in the habit of attending. They propose to charge the same fees as are charged at the dispensary; each medical man will see patients at his own house, and in order to meet the convenience of members and to distribute the work more evenly they propose to see patients both morning and afternoon; while with regard to any clubs attached to the dispensary which might wish to continue under their care, they propose to see members every evening instead of as at present one evening per week. A house is being fitted up as a dispensary. These conditions should make for a better state of things than that which has prevailed in the institution. The medical men now receive 2s. 2d. per patient per year, and it will be at once apparent as a matter of arithmetic that to earn the larger sums stated above several thousand patients must be dealt with in the course of a single year. No official statement is made as to the number of members in the dispensary, but it is known to be, including club patients, well up to 22,000. Such a number takes out a large slice of the population to be estimated when a medical man may be contemplating buying a practice or starting a practice in Coventry. Moreover, it may be assumed that the club men are followed to their own medical attendants by members of their respective families.

There was much discussion at the dispensary meeting on the question whether the future dispensary staff would be able to secure consultations, keeping in mind the circumstances in which they will have gone to Coventry. It would seem that the dispensary committee is expecting to join the Friendly Societies Medical Association, and a speaker at the meeting stated that he had been informed by the secretary of the association that there was no difficulty now in obtaining consultations. With regard to the Midlands this is not so certain, for it is no secret that all through the efforts made to obtain reform in Coventry the co-operation of the Birmingham branch has been assured. It has been given out with an air of authority that the dispensary committee can secure the services of a sufficient number of medical men to carry on the work after the departure of Dr. Pickup, Dr. Hird, Dr. Fenton, Mr. Heal, and Mr. Arch. Any practitioner who contemplates taking such appointment will do well to become conversant with the facts of the case. The struggle going on is being watched with keen interest by the profession at large on the one hand, and by dispensary committees up and down the country on the other.

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

Local Hospital Reports.

At or about this period of the year the annual reports of the majority of the hospitals are being presented and it is the time when we can estimate most readily the amount of work that the hospitals are doing, its type, its cost, and the support which is being given by the general public. In previous communications I have drawn attention to the fact that continually increasing work must of necessity be associated with the continued increase of population, but unfortunately it is not associated with a corresponding increase of monetary support. The General Hospital is perhaps an exception, its income for the past year exceeding the expenditure, but even in its case the ominous statement was made that the amount received from subscriptions had fallen off. The reports of the Queen's Hospital, the Hospital for Sick Children, the Birmingham and Midlands Women's Hospital, and the Birmingham Skin Hospital all record increased work, excess of expenditure over income, and either diminution or inadequate increase in the amount of subscriptions. It would scarcely serve any good purpose at the present moment to analyse the causes which produce these results, but those more particularly concerned should note that the unsatisfactory position of subscriptions to hospitals is coincident with what is spoken of as a prosperous period. To pass to more detail, the General Hospital and the Hospital for Sick Children have been considered on previous occasions. The Queen's Hospital reports an income of £10,584, or £475 less than in the previous year, and an expenditure of £11,755. During the year 2307 in-patients and 34,213 out-patients were treated, making a total of 36,520, or 3235 more than in the preceding 12 months. The increase in the number of patients is very considerable and is no doubt partly due to the new service of trams which takes patients to the doors of the hospital. A very satisfactory point in the report of this hospital is contained in the statement that in spite of the great increase of cases the expenditure has been slightly reduced. Progress is being made in connexion with the erection of new buildings. For this purpose a sum of £22,124 has been promised, of which £17,177 have already been paid into the bank. It is found, however, that the greatly increasing pressure in the out-patient department will necessitate an extension of the scheme and an additional sum of £12,000 will be required. The record of the Women's Hospital, except so far as finances are concerned, is particularly good. Both in-patients and out-patients have increased in numbers; 728 operations were performed, or 238 more than in 1905, and amongst these were 391 cases of abdominal section, with an extremely low death-rate of 2.3 per cent. It is true that the death-rate is not quite so low as in the previous year, when it was 2.1 per cent., but it is very satisfactory and is far below the average. In the Skin Hospital the in-patients increased by 16 and the out-patients by 272, as compared with 1905. The expenditure was £173 more than in 1905 and the receipts were £37 less, the total excess of expenditure over income amounting to £235.

Proposed Sanatorium for Consumptives.

Two years ago the council instructed the health committee to consider the sanatorium treatment of pulmonary tuberculosis. The committee proceeded carefully and thoroughly into the matter; it has obtained a large amount of information and at an early meeting of the council it will recommend that active steps should be taken. The medical officer of health, Dr. J. Robertson, strongly urges that a municipal sanatorium should be provided for the double purpose of dealing with curable cases and educating the people with regard to the proper means of fighting the disease, and the committee will propose that the council should purchase an estate on the Leckhampton Hill, about three and a half miles from Cheltenham. The mansion which stands on the estate could be utilised for administrative purposes, the grounds are admirably situated, they lie 600 feet above sea level, and there is plenty of room for the erection of the necessary buildings. The estate includes not only the mansion and the surrounding 58 acres of ground but also a farm of 320 acres with a farmhouse and 12 workmen's cottages. The mansion and the surrounding 58 acres

would have been quite sufficient for the purpose in view, but it cannot be obtained alone, for the estate is to be sold as it stands. Possibly if the council determines to buy it it may prove eventually to be a good investment, though, the present return from the rental of the farm and cottages is not great.

An Instructive Exhibition.

In the National Trades Exhibition which is being held in the Bingley Hall a most instructive section is devoted to "sweated industries." The work is monotonous and sufficiently depressing as it is done in the comparatively large space devoted to it at the exhibition, but that is not its chief defect, for looked at from a medical point of view it suggests great possibilities of danger and disaster, when it is remembered that much of the work is done in the workers' own homes amidst what must be in many cases most insanitary surroundings. It matters not whether we who buy pay much or little, the danger is there, though it may be greater the less we pay; but how many of us ever inquire whether the things we use were made in a healthy workroom or amidst such surroundings as a worker can secure who can only earn from 16s. to 18s. a week after working from 10 to 12 hours a day? The danger of infection with diseases we would avoid lies in the clothes we and our wives and children wear, the hooks, the safety pin, and buttons with which we fasten the clothes; in our artificial flowers, in our umbrella bands, in the embroidery on ladies' slippers, in the pill boxes we sometimes use, in the metal boxes which are more frequently in our hands, and even the Bibles we read, for their pages may have been folded under insanitary conditions, at the rate of 1d. per 100 sheets. Looked at from a purely sanitary point of view it is quite clear that manufacturers should not be allowed to give out work to be done in the workers' homes, and we must be prepared to face the fact that the stopping of such home-done work will make still harder the lot of some of those whose lives are at present almost unbearable and that we shall have to pay a little more for our necessities.

Reafforestation.

The transformation of the ugly heaps of refuse and pit mounds which abound around Birmingham into tree-clad country is proceeding not very rapidly perhaps but still steadily and satisfactorily, and no one can doubt that the final result will be an increase in the physical and mental health of the surrounding population. The experimental stage has been passed and the Midland Reafforestation Society is continually gaining adherents. On March 23rd at a public meeting held in the Wolverhampton town hall a new local branch was formed, one of its objects being the reclamation of the at present hideous ground which lies between Wolverhampton and Birmingham. Speaking at the meeting Sir Oliver Lodge gave some interesting details of the work. He stated that the cost of planting was £5 per acre for large plots and a little more for small areas, and he pointed out that the association was not seeking for profit and could not expect any for 15 years, but after 20 years the profit on the planting would probably amount to 2½ per cent. compound interest from the time of planting. The long time which must elapse before any return is gained is one of the main difficulties which stands in the way of the association and retards most useful work.

April 2nd.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

Liverpool Consumption Hospital: Tuberculin in Pulmonary Tuberculosis.

THE annual report of the Liverpool Consumption Hospital contains the announcement that "the committee, acting on the advice of their medical board, have thought it their duty to equip a laboratory and appoint a pathologist in order that the patients of the institution may reap the full advantage of recent advances in medical science. These advances point to the possibility of estimating from hour to hour the patient's resistance to the tubercle bacillus and of raising or lowering this resistance at will." The medical board, in its report, states that there are at present 30 patients under treatment and that the results so far are distinctly encouraging. It emphasises the fact that the treatment is still in the experimental stage but adds, "Should the treatment ultimately prove successful, it must undoubtedly

revolutionise the treatment of consumption among the working class, as it would appear to render it possible to treat a working man without depriving his family of their livelihood." Whether this attempt of the Liverpool Consumption Hospital be successful or not, it will be agreed that it should be made and it is right to wish it every success. The benefit derived from the use of tuberculin in cases of surgical tuberculosis being well known, why should it not also succeed in pulmonary phthisis? So far only partial success has attended its administration. The question arises, Is a different tuberculin required in the latter case, or has it yet to be learnt when to give it and in what doses? These facts can only be obtained by experience, slowly acquired with the help of a well-equipped laboratory. Certainly no effort should be spared to acquire that knowledge. Anyone with practical experience of the treatment of pulmonary tuberculosis amongst the poorer classes must admit that in their case the sanatorium treatment is not satisfactory, for a simple reason that, to them, it becomes impossible. A patient cannot be maintained in a sanatorium for less than 30s. a week or thereabouts. This amount must be low by the individual or by philanthropic agency. Obviously only a favoured few can find so much. Nor is this a whilst under treatment in the sanatorium the patient ear nothing and his family is compelled to go "on the parish." The knowledge of this dread fact deters many from going to the sanatorium until the last possible moment, when it becomes too late. Whatever its absolute merits may consist in, the sanatorium is practically closed to the poorer classes for purely economic reasons. The solution of the problem may possibly be found in the use of some such vaccine as tuberculin.

Mr. Arthur J. Evans.

Mr. Arthur Evans, the medical officer of the steamer *Port Kingston*, who distinguished himself in connexion with the Jamaican disaster, had the honour of being presented to the Prince and Princess of Wales at Knowsley by the Earl of Derby on the evening of the Grand National day. His Royal Highness warmly congratulated Mr. Evans on his arduous and humane work during the great disaster and spent a long time in inquiring of him the particulars of the catastrophe. Mr. Evans was also introduced to Lord Roberts, who recognised in him a member of the medical staff who served with him in the South African war.

April 2nd.

WALES AND WESTERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENTS.)

Typhoid Fever at Pontypool.

DURING the epidemic of typhoid fever which prevailed in Pontypool and the adjoining districts in the autumn of 1906 there occurred in Pontypool 169 cases and 12 terminated fatally. Commenting upon the outbreak in his annual report the medical officer of health (Mr. S. B. Mason) states that he found that the water company had been supplying water from a well the water of which was alleged to be impure and that the iron pipes leading from the well were laid alongside a brook which received the sewage from several houses and from a slaughter-house. In flood time the pipes were covered with water, so that there was the possibility of secondary pollution. The Pontypool district council is advised by its medical officer of health to provide an isolation hospital, a steam disinfecter, a dust destructor, and a public slaughter-house, and to consider the desirability of providing a common lodging-house and efficient sewerage for the district.

Compensation for Tuberculous Cattle purchased by Butchers.

Some four years ago a form of mutual insurance was established in the Cardiff and Newport districts for the payment of compensation to butchers who at the public auctions purchased cattle which were subsequently found to be tuberculous and were destroyed. The contributions to the fund by the farmers, auctioneers, and butchers were very small and although only two-thirds of the value of the animal was paid to the purchaser the scheme has been found to work well. It is to be regretted therefore that the Newport butchers are desirous of withdrawing from the fund. They assert, as a reason for

value of a tuberculous carcass should be paid to the purchaser by the State.

The Sewerage of Bath.

The Somerset county council has for some time been endeavouring to persuade the corporation of Bath and the sanitary authorities of the adjoining districts to take steps to purify the sewage which at present is discharged untreated into the river Avon. The county council has been extremely patient and has postponed enforcing its powers under the Rivers Pollution Acts in the expectation that voluntary action would be taken by the sanitary authorities concerned. As this expectation was not fulfilled the county council decided to take definite action with the result that the corporation of Bath has at length admitted that the time has arrived when the future disposal of the city sewage should be dealt with. It is not, however, in any hurry to give practical effect to this opinion, and having regard to the enormous cost involved in carrying out any sewerage scheme, and to the uncertainty existing as to the best system to be adopted, it requests the county council to defer taking proceedings until the report of the Commission now sitting has been presented to Parliament. Some 12 years ago a very comprehensive scheme was considered by the corporation and was only abandoned on account of the great cost involved. Since then suburban Bath has increased to a considerable extent and many of the suburbs are outside the city boundaries. It would appear, therefore, desirable that a joint scheme should now be promoted by the Bath corporation and the neighbouring authorities.

Bristol Eye Hospital.

The ninety-sixth annual meeting of the subscribers of the Bristol Eye Hospital was held on March 27th under the presidency of the high sheriff (Mr. H. Daniel). The medical report stated that during 1906 the in-patients admitted numbered 454 and 6805 out-patients were treated, compared with 500 in-patients and 6250 out-patients in 1905. The financial statement showed that there was an unfavourable balance of £259.

SCOTLAND.

(FROM OUR OWN CORRESPONDENT.)

Proposed Testimonial to Professor J. G. McKendrick.

On the initiative of the business committee of the general council of the University of Glasgow it has been resolved to take steps to recognise in some appropriate manner, on the occasion of his retirement from the chair of physiology in the University of Glasgow, the long and distinguished services of Professor J. G. McKendrick as a scientific and public man and to give expression to the personal esteem in which he is held by his many friends throughout the country. The form of recognition will to some extent depend on the amount subscribed, but it is thought that the first object to be aimed at should be the presentation to Professor McKendrick of his portrait or bust by an eminent artist. It is understood that it would be specially gratifying to him if in addition it were possible to furnish, or assist in furnishing, a laboratory for experimental psychology in the new physiological buildings of the University of Glasgow. Experimental psychology, which deals with the practical examination of mental processes, lies between physiology and psychology and has always attracted a large part of Professor McKendrick's time and attention. So convinced is he of its importance that at his suggestion two rooms have been set apart for this subject in the new University buildings. Both in America and on the continent, and more recently in most of the universities at home, experimental psychology is fully established as a recognised study, and great progress has been made in the experimental examination of many phenomena connected with the interaction of body and mind. Further, in recent years the study of the characteristics and development of the mind in early life has come to be regarded as an important branch of the science of education, and there can be little doubt that the principles and methods of experimental psychology will soon form part of the training of teachers. For these purposes many costly and special appliances are necessary. It seems likely that the committee which has

charge of the scheme will be able to carry it through successfully, as the first list of subscriptions amounts to nearly £500.

Glasgow Hospital Sunday Fund.

The total income for the year from churches and Sunday schools, including donations and bank interest, amounted to £5079 3s. 1d., showing an increase of £248 8s. 2d. The sum set aside for distribution is £4830, and this will be allocated as follows: Royal Infirmary (580 beds), £2205 16s. 6d.; Western Infirmary (469 beds), £1783 13s. 7d.; and Victoria Infirmary (221 beds), £840 9s. 11d. One wonders a little at the precision which docks the Victoria Infirmary of one penny to present it to the Western Infirmary, but the Fund is to be congratulated on its work.

New Hospital in Skye.

Last week there was opened a cottage hospital recently erected at Uig on the Congested Districts Board's estate by the trustees of the late Mr. John Martin. The hospital has a fine situation on rising ground, overlooking the bay, and has a southern exposure. It consists of two wings providing two wards with three beds in each, with all necessary accommodation for matron and staff. The building has cost £1200 and Mr. James Coats, jun., of Paisley has generously furnished the hospital with a complete set of surgical instruments and appliances and also a fully equipped dispensary cabinet.

(FROM OUR OWN CORRESPONDENTS.)

Public Health of Dublin.

THE last fortnightly meeting of the public health committee was held in the municipal buildings on March 26th. Sir Charles Cameron reported that the death-rate for the two weeks ending March 23rd from all causes in the city was 25.9 per 1000 persons living, the mean death-rate in the corresponding period of the previous ten years being 31.9. In the Dublin registration area the general death-rate was 23.8 per 1000. Sir Charles Cameron reported that since March 6th three cases of epidemic cerebro-spinal fever had been returned, none of them in any house from which any previous case had been notified. In reference to a letter from the Dublin Cow-keepers' Association, transmitting a resolution passed by that body on the subject of boracic acid as a preservative of milk sent into the city from country districts, the committee passed a resolution as follows:—

The public health committee warn parents against the use of any milk containing boracic acid as likely to be injurious to health.

Royal Victoria Hospital, Belfast.

At the annual meeting on March 26th it was reported that during the past year there had been 3280 intern and 27,626 extern patients. Of the medical staff, Sir W. Whitla, Mr. A. B. Mitchell, and Mr. R. Campbell retired in rotation during the year, but were re-elected unanimously. The total income from all sources was £14,875 8s. 3d., while the expenditure has amounted to £15,253 1s. 6d. The sum of £10,136 19s. 1d. was added to the invested endowment fund during the past year.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Complete Dislocation of the Metatarsus Outwardly and of the First Cuneiform Bone.

On March 13th M. Walther read a paper on behalf of M. Soubotich of Belgrade who had had in his care a man, aged 50 years, presenting a curious little surgical injury. This patient, while going downstairs backwards in order to avoid falling, made a brisk movement of rotation. The front part of the left foot, however, did not follow the rest of the body in this movement and remained fixed. The patient developed outward dislocation of the metatarsus with rotation of the first cuneiform bone. A first attempt at reduction failed and failure was also the result of a second attempt made under chloroform. M. Soubotich then prescribed rest, massage,

and gentle movements. At the end of 15 days the patient began to walk and little by little the foot recovered all its functions, until 14 months after the accident, despite a little weakening of the plantar arch, the patient can use his foot naturally and without pain. M. Walther, in the course of reading the paper, exhibited some radiographs which he had taken himself of dislocation of the metatarsal bones outwards together with fractures of the cuboid bone. One of these cases occurred in a woman who walked well notwithstanding that she had had no treatment.

The International Exhibition of Urban Hygiene at Lyons.

An International Exhibition of Urban Hygiene will be held at Lyons from May 12th to 29th. It will coincide with various other meetings, among which is the visit of various British municipalities. The exhibition will be divided into 11 sections—viz., Dwellings, Drinking-water, Sewers, Highways, Buildings and Watercourses (*Voirie*), Municipal Buildings as a Whole, Schools, Infant Life Protection, Hospitals, Disinfection, General Sanitation of Towns, and the Fight against Prominent Social Evils (*Grands fléaux sociaux*). The exhibition is willing to receive anything which in any way is connected with urban hygiene. No charge will be made for exhibits or for floor space, but water, gas, or electricity consumed by any exhibitor will have to be paid for by him. Any information concerning the exhibition may be obtained by writing to Professor Jules Courmont, Laboratoire d'Hygiène, Faculté de Médecine, Quai Claude Bernard, Lyon.

Municipal Aid for Medical Education.

On the recommendation of M. Chautard the following sums have been allotted by the Municipality of Paris to medical education: to the Municipal Chair of Clinical Gynaecology, 15,400 francs; to the Municipal Chair of Clinical Surgery in Children, 15,400 francs; to the Municipal Chair of Biological Chemistry at the École de Pharmacie, 12,000 francs; for bursaries at the Faculty of Medicine, 5000 francs; for the Library of the Medical School, 2000 francs; for M. Obarran, Laboratory of Experimental Medicine, 2500 francs; to the Physiological Station at Parc des Princes, 7000 francs; to the School of Anthropology, 9000 francs; and to the Pasteur Institute, 12,000 francs.

Gunshot Wound of the Lung.

At a meeting of the Society of Surgery held on March 13th M. Burnier gave an account of this case in his own name and in that of his interne. The patient was a man, aged 36 years, who had received two bullets from a revolver in the præcordial region. The interne proceeded to operate as the case was very urgent. A flap of the whole thickness of the chest wall was turned up, which included the second, third, fourth, and fifth ribs, and dark-coloured blood was seen in the pleural cavity. One of the bullets was found under the visceral pleura and was extracted. The lung, which was wounded in four places, was sutured and the pleural cavity dried out with compresses. Drainage was made at the posterior and lower portion of the pleural cavity and the patient made a steady recovery.

Gunshot Wound of the Kidney.

At a meeting of the Surgical Society held on March 27th M. Walther read an account of the above case on behalf of M. Duval, a naval surgeon. At the operation the whole of the lower half of the kidney was found to be smashed and hæmorrhage was very abundant. A lumbar nephrectomy was performed and four days later signs were observed in the wound of an intestinal fistula. The fistula, however, closed spontaneously after a little time. It seemed likely that the colon had been bruised by the ball with the result that the wall of the bowel sloughed and so gave rise to a fistula.

ITALY.

(FROM OUR OWN CORRESPONDENT.)

Cerebro-spinal Meningitis.

In its wide diffusion this malady has not spared Italy, where, particularly in great commercial and industrial centres like Milan, it is still claiming many victims, young, adult, and elderly. In an interesting lecture before a post-graduate audience Dr. Edoardo Bonardi, professor of special pathology in the University of Pavia, seems to have thrown fresh light on the disease or, at any rate,

to have started a theory already fruitful in instructive controversy. In the case of a boy presenting the "quadro classico" (classical picture) of cerebro-spinal meningitis he drew attention to two important features—one of them clinical, the other bacteriological. Coincidentally in the little patient with the cerebro-spinal meningitis there existed a "croupal pleuro-pneumonia of the right side," and the bacteriological examination of the "cephalo-rachidian liquid, extracted by lumbar puncture," yielded in the dry preparations, as in the cultures, the "diplococcus capsulatus of Tolamon-Fränkel"—the identical pathogenic germ of croupal pneumonia. Professor Bonardi concluded, therefore, that the case was one of "cerebro-spinal meningitis metapneumonia," differentiating it from the epidemic cerebro-spinal meningitis as "meningococcus intracellularis meningitidis," a form clinically more serious as being more malignant. Some of his colleagues objected that "there is no difference between the diplococcus capsulatus" and the "meningococcus intracellularis." To which Professor Bonardi replied that that view is rather out of date and not generally accepted and referred his critics to the recent monographs of Jüger and Marchal, the former of whom, dealing with the morphology of the meningococcus intracellularis, approximates it to the "gonococcus" and the "staphylococci," asserting that it has nothing in common with the "diplococcus pneumonius." Marchal, moreover, analysing 513 cases of cerebro-spinal meningitis bacteriologically dealt with, puts 69.2 per cent. *en rapport* with the meningococcus of Weichselbaum and 28.8 per cent. with the "diplococcus capsulatus" of pneumonia, "which two micro-organisms," continued Professor Bonardi, "are usually distinguished with a rapid (dry) examination of the cephalo-rachidian liquid, comporting themselves frequently in an opposite manner with the method of Gram. Now," adds Professor Bonardi, "the relation between the meningococcus and the gonococcus sustained by Jüger is confirmed by sero-diagnosis—the one micro-organism and the other being agglutinated by the same (immunised) serum of the boy patient now convalescent from cerebro-spinal meningitis. As for the possibility of contagion, concludes Professor Bonardi, in cerebro-spinal meningitis "it undoubtedly exists. No one denies nowadays the contagiousness of typhoid or of croupal pneumonia, although in our hospitals patients yielding these infections are to be found associated with others in a common ward! Let the patients from cerebro-spinal meningitis, therefore, be isolated but equally so let those suffering from pneumonia, keeping in mind that the channels of contagion, numerous and in the main indirect, remain hidden for relatively long periods of incubation."

"Salviamo i Bambini Poveri."

"Let us save the poor children" is an appeal made to the Government by Professor Luigi Concetti, Director of the *Pediatric Clinique* in Rome. Malaria, he urges, is, in the Italian communes, the chief enemy of infancy, either carrying them off after a brief illness or rendering them anæmic, or lowering their resisting power to all the more prevalent maladies, while inflicting often irremediable mischief on the digestive apparatus. Quinine, invaluable as a prophylactic or as a cure in malaria-affected children, is repugnant to them from its taste, nor even when that is disguised in wafers or tablets or lozenges is it easily swallowed. Preparations like "enquinina" or "aristo-quinina" (common enough in Italy) are too dear to be within the reach of the poor. Moreover, nearly all the above-named forms in which the drug is exhibited are found to have their objectionable qualities, causing in children diarrhoea, cardiac trouble, drowsiness, and, in the long run, asthenia. The tannate of quinine, being insoluble and not bitter, has for the last ten years been most generally administered. Not only was it well tolerated, but by reason of the tannic acid it corrected the diarrhoea so often resulting in malaria and caused no nervous disturbance. However, it was given up because it was "insoluble." That objection no longer exists. Like many foods and many drugs which are insoluble in water, it is easily reduced to the liquid state by the gastric and intestinal juices and so gets readily absorbed and passes into the system. Quite lately the *Laboratoria del Chinino di Stato* (State Laboratory of Quinine) has devised a preparation which removes all difficulty in exhibiting the salt and by incorporating the tannate with cocoa and sugar it has produced a "cioccolato-lattino" (a chocolate bon-bon) which children take readily

and even eagerly. The State is now appealed to on the score of economy, so as to cheapen the bon-bons down to the purchasing power of the very poor; and it is confidently expected that its response will be such as to leave no commune, however indigent, without access to a remedy efficacious beyond all others in combating the national scourge.

March 30th.

VIENNA.

(FROM OUR OWN CORRESPONDENT.)

Centenary of the Operateurinstitute.

THE centenary of the foundation of the Operateurinstitute or school for surgeons in Vienna, which was established by the Emperor Francis I. on the suggestion of Dr. Kern, was celebrated, together with the eightieth anniversary of the birthday of Lord Lister, by a special meeting of the Gesellschaft der Aerzte. The institute has during the century of its existence been a very important means of instruction for surgeons. It was attached to the two surgical clinics of the University of Vienna in 1863, but was previously under the immediate control of the professor of surgery for the time being and the expenses incurred in the instruction of the surgeons were till that time paid by the Emperor. The growth of the institute and the importance of its influence on the present generation of surgeons may be judged from the facts that in 1863 there were 56 operations performed, whilst in 1899 the number was 712, and all the modern achievements of surgery attained in Austria are due to the pupils of the Operateurinstitute. Professor Billroth was the only head of this school who had not been also a pupil of it. An address was delivered in honour of Lord Lister, whose discoveries had revolutionised surgery and had thereby profoundly influenced the institute. There was also a reception of former and present pupils of the school, who comprise several professors, *privat-docenten* and directors of hospitals, along with of other surgeons.

Influenza in Austria-Hungary.

Influenza has again been epidemic this year in Central Europe, especially in Austria, and the death-rate was high, whilst the incidence of morbidity was increased by fully 20 per cent. As a rule the complications were of a mild type and involved mostly the ear and the gastro-intestinal tract, whilst the primary attack was almost invariably localised in the upper air passages. The rapid changes in the weather, which especially in the months of January and February caused differences of temperature ranging from 18° to 20° C. in six or eight hours, were very favourable to the development of catarrhal diseases, amongst which influenza had a foremost position. During the last few years influenza has been made one of the notifiable infectious maladies, but many practitioners have shown much laxity in conforming to the regulation. The official statistics therefore report only a slight increase of influenza, whilst the complications, which were undoubtedly of a post-influenzal nature, are not shown in these statistics. The sudden changes of the weather also had an unfavourable effect on the mortality amongst infants. The number of hours of sunshine was reduced by 20 per cent. in comparison with the average for the last 50 years, so that the antiseptic power of the sun's rays had less opportunity of making itself felt.

Pseudo-Hermaphroditismus Masculinus.

At a recent meeting of the Gesellschaft der Aerzte Dr. Halm showed two sisters each with the same malformation. The elder one, who was 20 years of age, sought medical advice on account of the non-appearance of menstruation. It was found that she presented a series of masculine characteristics, such as a well-developed larynx, absence of mammae, an exuberant growth of hair on all parts of the body, and a masculine arrangement of the pubic hair. As regards the genital organs the clitoris was very large, imperforate, and covered with a large prepuce, and the vagina was a short closed canal hardly admitting one finger. No trace of a rectum. In the right labium there was a hard nodule of the shape of a testicle, which Dr. Halm believed to be a testicle. She had been brought up as a girl, but had never felt herself drawn to the other sex. The younger sister, who was 13 years old, showed similar conditions, the only difference being that in the labia she had two

of the nodules resembling testicles. The family history was unimportant except that the grandfathers of the parents were brothers. The father of the girls asked to have the two testicles of the younger girl removed, whilst the elder girl suffered from time to time from pains in her testicle, so that the question arose whether this operation, which might be called castration, was justified. The existence of these malformations naturally gave rise to some difficulty in the selection of an occupation for the girls.

Ulceration of the Skin after Diagnostic Application of the X Rays.

It is not often that a single cautious application of the x rays for the purpose of ascertaining the presence of metallic objects in the human body leads to grave consequences. Such a case, however, was shown by Professor Lang at the same meeting of the Gesellschaft der Aerzte. The patient was a man who had been suspected of having swallowed several rusty nails when in a psychopathic condition. The results of the examination by the x rays were negative, but 12 days afterwards the skin which had been exposed to the rays became inflamed and after two more weeks an ulcer formed. This ulcer showed no tendency to heal and after the lapse of a year covered an area of about 20 square centimetres. An operation was then performed in which the skin of the neighbourhood was also removed and the deep layer of the fascia and even fibres of the muscles were excised. The final result was a defect of about 80 square centimetres, which was covered by the Thiersch method. At the present time, one year after the operation, the scar tissue extended to about 100 square centimetres, was of excellent quality, and was freely movable, without any fixation to the muscles. Professor Lang laid special stress on the necessity of deferring surgical interference in such cases until the degenerative process had ceased.

March 27th.

NEW YORK.

(FROM OUR OWN CORRESPONDENT.)

A National Endowment for the Improvement of Social Conditions.

AMONG the bequests which possessors of great wealth in the United States are making for the benefit of the people of the whole country the most striking is that of the widow of the late Mr. Russell Sage. Mr. Sage was a banker, who began life as a country lad, of humble origin, but who developed remarkable talents for business in whatever position he was placed. He came to New York after a successful career in a country town, having a very moderate fortune at his command. During the 50 years of his financial operations in this city he accumulated a fortune of upwards of \$80,000,000, which he left at the disposal of his widow, a lady of education and refinement, without heirs. Her first considerable gift of this immense estate is \$10,000,000 to create a "Russell Sage Foundation," the object of which is stated to be "the improvement of social and living conditions in the United States." The means to that end will include research, publication, education, the establishment and maintenance of charitable and beneficial activities, agencies, and institutions, and the aid of any such activities, agencies, and institutions already established. It is an interesting fact that the endowment of great national beneficence in this country by men of large wealth had its origin in the gift of Mr. George Peabody of London soon after our Civil war, to endow an organization for the promotion of education in the Southern States. This was followed by the Carnegie foundation of \$10,000,000 in aid of educational institutions, and, finally, by the Rockefeller Foundation of \$32,000,000 for specific lines of national education and philanthropy. The "Russell Sage Foundation" is the first contribution by a single person of wealth towards the national betterment of the social and living conditions of the people.

Honours conferred on a Physician.

The Congress of the United States has passed a special Act, authorising the President to appoint Lieutenant and Assistant Surgeon James Carroll, U.S. Army, a Surgeon with the rank of Major. The President promptly complied. Dr. Carroll's special claim to the honour conferred upon him is due to his voluntary submission while with the army in Cuba to test in his own person the effect of the bite of a mosquito infected with yellow fever. The test was made on

August 27th, 1900; on August 31st, four days after the bite, he was taken sick and sniffered a severe attack of the fever; he was confined strictly to bed until Sept. 13th and convalesced slowly, leaving Onba on Oct. 9th on sick leave. Dr. Carroll was born in England in 1854 and came to the United States by the way of Canada and soon after enlisted in the army. He studied medicine while serving in the army, and on graduation, took a course of graduate work in pathology and bacteriology at Johns Hopkins Hospital. In 1893 he again entered the army service and became associated with Dr. Walter Reed and subsequently was detailed with Dr. Reed to study infectious diseases in the island of Cuba. It was in the course of these investigations that he submitted to the test of the infected mosquito. On returning from Cuba Dr. Carroll devoted his time to the study of the mosquito and was again detailed to continue investigations in Cuba. During this period he succeeded in procuring six more experimental cases of yellow fever, all of which recovered. In 1903 he demonstrated that the supposed protozoan parasites reported to have been found in yellow-fever infected mosquitoes were ordinary yeast cells. In the course of his work it was shown that the supposed cause of yellow fever described by Professor Sanarelli was closely related to the hog-cholera bacillus.

State of Legislation on Osteopathy.

The disciples of osteopathy show a persistency in their efforts to secure a legal standing and recognition worthy of a better cause. On Jan. 1st, 1907, 29 States had adopted some provision for the licensing of osteopaths. Of these, 11 had adopted amendments to the Medical Practice Act authorising existing State boards to examine and to license osteopaths. Three States have added an osteopath to the State board. In 11 States special osteopathic examining boards have been established. In three States osteopaths are exempt from the operation of medical practice laws. In one State they are allowed to pursue their calling after registration in the office of the county clerk. There are 20 States in which no osteopathic legislation has been secured, but in 12 osteopathic Bills are pending and in seven efforts are being made to amend existing Acts relating to osteopathy. It appears on close examination that all these efforts to secure legislation in so many States emanate from one central source, thus showing that the demand for the recognition of osteopathy by legislation is not among the people but has its origin and support in a single central organisation.

Council on Pharmacy and Chemistry of the American Medical Association.

The investigations by this council of the various advertised remedies are revealing the most astonishing frauds perpetrated upon the public by the manufacturers of these preparations. The most popular of these preparations are found to contain large quantities of alcohol. In a test case recently brought by the Commissioner of Excise it was decided that one of the most popular and widely advertised of these cure-all remedies was a beverage, instead of a medicine, owing to the fact that it contained 27 per cent. of alcohol and a small percentage of solids, not drugs. The justice proposed the following questions to the jury for decision—viz., 1. Is the preparation contained in the five bottles, produced by the plaintiff, consisting of water, alcohol, and certain drugs, a proper remedy for the cure of Bright's disease, acute catarrh, chronic catarrh, diseases of the mucous membranes? 2. Was the quantity of alcohol, 26 or 27 per cent., contained in the preparation necessary to hold the drugs actually put therein in solution? 3. Was the quantity of drugs contained in one bottle of the alcohol, diluted with water, sufficient in amount in tablespoonful doses, three or four times a day, to produce any appreciable remedial effect? The jury answered the three questions in the negative. The decision was that the preparation is not a remedy for any disease but that it is so much a liquor that the sale should require a liquor tax certificate. Bright's disease and consumption being the diseases now most feared by the public most of these nostrums are advertised to cure kidney and lung diseases. One of the most famous of the kidney cures, whose manufacturer is now a multi-millionaire, was found to consist of ordinary white sugar alone.

A Suicide Bureau.

The Salvation Army has established in New York what is to be known as a "suicide bureau." The object of the managers is to give good advice and, where needed, to give

material aid to those whose desperate circumstances have driven them to contemplate self-destruction. That such organisation will be of great service is proved by the fact that 18 persons applied on the first day.

March 26th.

Obituary.

HIS EXCELLENCY ERNST VON BERGMANN.

PROFESSOR OF SURGERY IN THE UNIVERSITY OF DRESDEN

The medical profession in general, and that of German in particular, has sustained a heavy loss by the death of His Excellency Professor von Bergmann, Real Privy Councillor, professor of clinical surgery and director of the surgical clinic of the Royal University, and surgeon-general à la suite of the German army. He is mourned alike by his professional brethren and by the public at large, for it may be said that of all the members of the Berlin medical faculty he was the most popular among every class of the population of the city. His death is the more felt by his friends because on the seventieth anniversary of his birthday, which was celebrated a few weeks ago, he was the recipient of many tokens of sincere esteem alike from his medical colleagues and his numerous patients and then then seemed no evidence of any illness or weakness. Only a very few of his most intimate friends knew that notwithstanding his apparent health and vigour, Professor von Bergmann had been suffering for nearly three years from periodical attacks of severe abdominal pain and that he had himself made the diagnosis of cancer, although this opinion was not shared by his medical attendants. A fortnight ago, at the beginning of the Easter holidays, he went for treatment to Wiesbaden because of sciatic pains in the left hip and a general feeling of uneasiness caused, as he believed, by overwork last winter. At Wiesbaden he apparently recovered, but on March 23rd abdominal symptoms suddenly developed. The family at his request telegraphed to Professor Schlange of Hanover, one of his pupils and also a highly esteemed former assistant, who at once, together with Dr. Stein of Wiesbaden, performed colotomy under local anaesthesia, as the weakness of the patient's heart contra-indicated the administration of a general anaesthetic. The serious symptoms, however, continued after this operation, so that Professor von Bergmann insisted on a second one, which was accordingly performed on the morning of March 25th. A few hours afterwards collapse occurred and at 11 A.M. Professor von Bergmann breathed his last in presence of his family and of several of his former and present assistants who had gone to Wiesbaden on hearing of his illness. At the necropsy it was proved that the disease was not cancer but obstruction caused by old adhesions of the colon and suppurative peritonitis.

Professor von Bergmann was born in 1836 in Riga, the capital of the Russian Baltic provinces and the birthplace of not a few men who have attained eminence in various ways. He was the son of a clergyman of noble birth and had the intention of becoming a clergyman himself. After the completion of his preliminary studies at the gymnasium of Riga he presented himself for matriculation at the University of Dorpat as a student of theology, but was refused permission as the Emperor Nicholas, who at that time governed Russia, had ordered that the number of theological students in Dorpat should be limited according to the number of existing incumbencies, and when young Bergmann applied he found that there were no vacancies. A similar state of affairs existed in the Faculty of Jurisprudence, where he also sought for admission, and he was thus forced to matriculate in the Faculty of Medicine, where there were no restrictions on the number of students. It was thus by accident that the deceased became a medical student and that he ended his life, not as a clergyman in some remote town or village of the Russian Baltic provinces, but in Berlin as the world-renowned surgeon of the greatest German University.

After having completed with success his medical curriculum at the University he became qualified in 1860 and was then appointed an assistant in the surgical clinic, first under Professor von Oettingen and then under Professor Adelman. In 1864 he obtained recognition as a private docent. In 1866 he took part as a volunteer surgeon

HIS EXCELLENCY PROFESSOR ERNST VON BERGMANN,
PROFESSOR OF SURGERY IN THE UNIVERSITY OF BERLIN.

from an attack of pulmonary tuberculosis and had also held an appointment at the Cotswood Sanatorium. He was appointed medical superintendent of the Devon and Cornwall Sanatorium about two years ago. Mr. Fleming was extremely popular and was much liked by the patients for his kindness and consideration. He was a good sportsman and hunted regularly with the Dartmoor hounds. Mr. Fleming was married two years ago and leaves a widow and one child. The funeral, which took place at Brent parish church on March 27th, was largely attended, amongst those present being many members of the medical profession from Plymouth.

Medical News.

UNIVERSITY OF LIVERPOOL.—At examinations held in March the following candidates were successful:—

DEGREES OF M.B. AND CH.B.

Second Examination.—Part A: L. S. Ashcroft, K. J. O. Bradshaw, L. Buckley, A. G. W. Owen, J. A. Parkes, J. F. Roberts, and N. W. Steinberg. Part B: S. P. Sykes.

Final Examination.—Part II: G. W. N. Joseph (Second Class Honours).

DEGREE OF B.D.S.

Third Examination.—H. Chapman.
Final Examination.—E. L. Cunnell.

DIPLOMA IN TROPICAL MEDICINE.

A. Bond, M. H. G. Fell, R. H. Kennan, W. H. Kenrick, G. B. H. Le Fanu, and H. Vallance.

VICTORIA UNIVERSITY OF MANCHESTER.—At examinations held in March the following candidates passed in the subjects indicated:—

FINAL EXAMINATION.

Part I.—J. A. Bateman, T. B. Bolton, W. O. Denniston, T. B. Dickinson, Edward Gandy, Frances M. Huxley, E. K. Lomas, S. S. Mahamadi, W. P. Marshall, W. W. Martin, John Morley, J. H. Nichol, M. O. Skillern-Lawrance, W. W. Stacey, John Thompson, R. B. Thompson, B. W. E. Trevor-Roper, W. W. Uttley, T. G. Williams, and A. E. Woodall.
Part II.—T. G. Burnett, Jane A. Fleming, S. H. Gandhi, J. T. B. Hall, W. H. Judson, W. P. Moffet, F. R. Parakh, J. B. Macalpine, W. H. Ross, and Harold Spurway.

The following candidates satisfied the examiners in the subjects of forensic medicine and public health:—

J. W. Bride, J. F. Dow, J. A. Falser, Frank Hartley, Robert Lakto, S. B. McClatchey, J. L. Moir, Peter Moran, Wilfrid Nightingale, Alice Oberdorfer, Robert Robertson, Elsie M. Royle, G. B. Warburton, and Henry Whitehead.

SECOND EXAMINATION.

A. Anatomy and Physiology.—H. E. Allanson, D. I. Connolly, F. H. Diggle, John Gow, T. J. Higgins, R. A. Jackson, N. T. K. Jordan, Niel McDonald, Edith M. Maraden, C. B. Marshall, G. B. H. Nicholls, Cedric Pimblett, Harry Platt, Alexander Porter, James Ramsbottom, A. A. Smalley, Norman Tattersall, R. H. Titcombe, and J. F. Ward.

Anatomy.—R. J. Batty.
B. Materia Medica and Pharmacy.—Estelle I. B. Atkinson, G. M. Benton, J. F. Cocker, Gertrude H. Geller, and F. G. Wrigley.

FIRST EXAMINATION (NEW REGULATIONS).

Materia Medica and Pharmacy.—G. S. Bate and W. J. A. Quine.

FACULTY OF DENTISTRY.

Third B.D.S. Examination.—Arnold Renshaw.
Third L.D.S. Examination.—J. L. Reynolds and Albert Torkington.

The annual general meeting of the Association of Medical Men receiving Resident Patients was held at 8, Henrietta-street, Covent Garden, London, on March 27th. Dr. D. Walsh, the President, was in the chair and nine members were present. The minutes of the previous annual meeting having been read and confirmed the honorary secretary read a statement describing the position and progress of the association, which gave rise to an interesting discussion. The following motions were then unanimously agreed to:—

1. That there shall be one honorary secretary (who shall also be honorary treasurer) resident in London who shall be empowered to spend a small sum yearly out of the association's funds for assistance in purely clerical work. He shall be supported by a committee of 12 members, four to form a quorum, who shall meet at least twice a year. One of the meetings shall be at the end of the financial year for the purpose of preparing the annual report and passing the statement of accounts. The committee shall consist of London and country members, who shall be elected by the annual general meeting; they shall have power to elect their own chairman, who shall have a casting vote; they shall also have power to fill any vacancies which may occur during their year of office.
2. That any eligible medical practitioner wishing to join the association subsequently to August 31st in any year shall pay the usual entrance fee of one guinea and 5s. as subscription for the remainder of the financial year.

Dr. Walsh was unanimously re-elected President. Dr. H. Bin was unanimously appointed honorary secretary and honorary treasurer. Dr. G. E. R. Crallan's name was added to the list of vice-presidents and he was accorded a vote of thanks for his services as honorary secretary and honorary treasurer to the association since its formation in 1899.

On March 26th, Mr. William Henry Waterfield, L.R.O.P., L.R.C.S. Irel., was returned for the third time at the head of the poll for the Stonehouse (Devon) board of guardians.

LONDON COUNTY COUNCIL: SCHOLARSHIPS FOR STUDENTS OF MIDWIFERY.—In July, 1907, the London County Council will proceed to award not more than six scholarships to students in midwifery. Candidates must be ordinarily resident within the county of London and must be between 24 and 40 years of age on July 31st, 1907. The value of each scholarship will be £25 and the course of training will extend over a period of six months. Forms of application may be obtained from the executive officer, Education Offices, Victoria Embankment, W.C.O., and must be returned to the same address not later than Saturday, April 20th, 1907. Further information may also be obtained on application to this address.

LITERARY INTELLIGENCE.—Messrs. W. B. Saunders Company will publish almost immediately a new work on *gynaecology and abdominal surgery*, edited by Howard A. Kelly, M.D., and Charles P. Noble, M.D. In view of the intimate association of gynaecology with abdominal surgery the editors have combined these two subjects in one work. The operations and procedures described in the text are illustrated by some 650 original illustrations, the work of Max Brodel and Hermann Becker of the Johns Hopkins Hospital, Baltimore.—Messrs. Putnam's Sons will publish early next week a translation from the German of Dr. J. Starke's treatise on "Alcohol; The Sanction for Its Use Scientifically Established and Popularly Expounded by a Physiologist."

UNIVERSITY OF LIVERPOOL.—The newly created chair of cytology has been filled, Mr. John Edmond Salvin Moore having been elected to the post by the Council of the University. Mr. J. E. S. Moore has had a distinguished academic career and since the year 1905 has been director of the cancer research laboratories at the University. He has been leader of two research expeditions to Tanganyika, and amongst other works he is the author of a publication entitled "Exploration and General Zoology." The Council of the University, on the recommendations of the Senate and the Medical Faculty, has elected Mr. Courtney Yorke to the Holt Fellowship in Physiology and Pathology and Dr. F. A. G. Jeans to the Scholarship in Surgical Pathology.

THE SOCIETY OF ARTS.—The lecture arrangements for meetings during April and May include the Cantor lectures on April 15th, 22nd, and 29th by Professor Herbert Jackson, F.I.O., F.O.S., his subject being *Detergents and Bleaching Agents used in Laundry Work*; on April 24th Mr. Herbert Wright, Controller of the Government Experimental Station, Ceylon, will read a paper on *Rubber Cultivation in the British Empire*; on May 8th Mr. Paul Schlicht will discuss the *Production of Coke and its Application to Domestic Fires*; on May 15th Dr. Herbert W. G. Macleod will take for his subject *Trypanosomiasis or Sleeping Sickness*; and on May 30th Mr. Laurence Robertson, I.O.S., will discourse on *Irrigation Colonies in India*. With the exception of the last-mentioned lecture, which will be delivered at 4.30, the lecture hour in all cases is 8 P.M.

DEPLORABLE MEDICAL POSITION AT NOVO NIKOLAEVSK.—The Governor-General of Tomsk, Baron NIKOLAEVSK.—The local correspondent of the *Novos Vremya*, Nollen, says the local correspondent of the *Novos Vremya* has gone to St. Petersburg to report on the tragical situation of Novo Nikolaevesk. He was accompanied by a representative depulution from the distressed town which numbers 45,000 inhabitants. Referring to the medical position, our Russian contemporary says that the morgue is a place seven feet square, covered with filth, without any usual accessories. In the summer the necropsies are carried out in the open air. The blood drops to the ground and the viscera are buried there. Then the town and the viscera are scratched them up. The medical staff pigs come and overpowered with work. The hospitals are in a frightful condition and do not afford a

tenth of the required accommodation. Infections and common cases are huddled together in one ward and often on the floor. In some there is no surgical department and surgical cases have to be taken several versts to a "transfer hospital."

A NEW ISOLATION HOSPITAL.—The new isolation hospital for the Merthyr Tydfil borough council was formally opened on March 30th. The hospital, which has been built about a mile from the centre of the town, has been erected at a cost of £13,500 and provides accommodation for 30 patients.

MEDICAL MAGISTRATES.—Mr. W. Black Jones, M.D., B.S. Lond., D.P.H., of Llangammarch Wells, has been placed on the commission of the peace for Brecknockshire.—Mr. Alfred H. Carter, M.D. Lond., F.R.C.P. Lond., professor of medicine in the University of Birmingham, has been placed on the commission of the peace for the county of Worcester.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

Progress of Bills.

THE House of Commons adjourned for the Easter recess on March 27th when the first of the three parts into which the Parliamentary session divides itself was over. Since the House met in February nearly 150 Bills have been introduced, but the vast majority of them have not yet reached a second reading. Amongst the Bills which still await the second reading stage are the Advertisements Regulation Bill, the Butter and Margarine Bill, the Coroners Bill, the Coroners' Inquests (Railway Fatalities) Bill, the Dogs (Injuries to Persons) Bill, the Education (Administrative Provisions) Bill, the Education (Scotland) Bill, the Housing of the Working Classes Act Amendment Bill, the Infant Life Protection Bill, the Nurses Registration Bill, the Parochial Medical Officers (Scotland) Bill, the Education of Afflicted Children (Ireland) Bill, the Pharmacy Bill, the Poisons and Pharmacy Bill, the Municipal Milk Depôts Bill, the Prevention of Cruelty to Children Bill, the Public Health Bill (Mr. J. W. Wilson's measure), the Public Health Officers Bill, the Public Health (Regulations as to Food) Bill, the Released Persons (Poor-law Relief) Bill, and the Sale of Whisky Bill. Most of these measures, owing to the restrictions placed by the rules of the House on the opportunities for the advancement of private Members' Bills, will probably not even get a second reading this session. A few of them, including the Butter and Margarine Bill, the Education (Administrative Provisions) Bill, the Education (Scotland) Bill, the Municipal Milk Depôts Bill, the Poisons and Pharmacy Bill, the Public Health (Regulations as to Food) Bill, and the Released Persons (Poor-law Relief) Bill stand as Government measures in a different category. Some of them are to be pressed forward soon after the House reassembles, and the Government has it in its power to allocate to their advancement such of the time at its disposal as may seem necessary. Amongst the few private Members' Bills which have got beyond the second reading stage are the Education Act Amendment Bill and the Education (Provision of Meals) (Scotland) Bill. The former has passed through committee, the latter awaits consideration by the Standing Committee on Trade.

The Municipal Milk Depôts Bill.

The text of the Bill introduced in the House of Commons by the President of the Local Government Board "to authorise and regulate the establishment of milk depôts by certain local authorities" has been issued. Under it the Common Council of the City of London, or the council of any metropolitan or municipal borough or urban district in England with a population of 50,000 or upwards, "may, subject to regulations, establish and thereafter maintain depôts for the sale of milk specially prepared for consumption by infants under two years of age, and purchase and prepare milk and provide such laboratories, plant, and other things, and exercise and perform such other powers and duties, as may be necessary for the purposes of this Act." If the council of a borough or urban district containing a population above 10,000 but below 50,000 obtains the consent of the Local Government Board it may put this provision of the Bill in force within its area. The Local Government Board is given power to make regulations as to the sources of the milk, as to its nature, and as to the manner in which, and the conditions under which, it is to be purchased, conveyed, and sold. The regulations may include provisions as to the classes of persons to be supplied and as to the visitation of their homes.

Public Health Officers.

Sir Walter Foster's Bill to amend the law relating to the qualification and tenure of office of medical officers of health and sanitary

inspectors has just been printed. The measure is backed by Sir FRANCIS POWELL, Sir JOHN BATTY TUCKER, and Mr. RANKIN. The main objects of this Bill are to secure that none but those properly qualified shall be appointed as medical officers of health or sanitary inspectors, and to give them security in their tenure of office similar to that enjoyed by Poor-law medical officers and metropolitan medical officers of health. The first clause of the Bill lays down that no one shall after Sept. 29th, 1909, be appointed a medical officer of health unless he is a duly qualified medical practitioner, and unless either (a) he is registered on the Medical Register as the holder of a diploma in sanitary science, public health, or State medicine under Section 21 of the Medical Act, 1886; or (b) he has for three consecutive years before the commencement of this Act served as a medical officer of health of a district or combination of districts with a population, according to the last published census, of not less than 50,000; or (c) the Local Government Board consents to his appointment.

Under Clause 2 of the Bill a medical officer of health or sanitary inspector shall not hold office or be appointed for a limited period only, and he shall be removable only subject to an appeal to the Local Government Board. This provision is to apply to every medical officer of health or sanitary inspector, notwithstanding any contract to the contrary. By the terms of the Bill an urban authority will have the power to appoint two or more sanitary inspectors. It is not proposed to extend the Bill to Scotland or Ireland.

The Housing of the Working Classes Act Amendment Bill.

A clause in Sir Walter Foster's Housing of the Working Classes Act Amendment Bill places a new power in the hands of medical officers of health. Under it, it shall be the duty of the medical officer of health of every rural district to represent to the council of that district cases where danger arises to the health of the inhabitants of any portion of it from the insufficiency or unwholesomeness of the existing supply of housing for the working classes. It is further laid down that if four or more householders in a parish or other affected area complain in writing of such a danger to the medical officer of health it shall be his duty to make an inspection of the houses and to transmit the complaint along with his observations to the district council. The rural district councils must then take the matter into consideration. For rural district councils which adopt the measure an elaborate procedure is laid down as to the purchase and hiring of land and the erection of houses. Certain clauses of the Bill deal with cases where rural district councils do not adopt its provisions.

Medical Examination of School Children in Scotland.

Mr. SINGLAI, in introducing the Education (Scotland) Bill, mentioned that it would make provision for the medical examination of children. The text of the Bill, which was published on the day after the House of Commons rose for the Easter holidays, now shows the terms of the proposal of the Government. Clause 4 lays down that a school board may on its own initiative (or where required by the Education Department) provide for the medical examination and supervision of children attending schools under its charge, under provisions prescribed from time to time by any code or minute of the department. For this purpose the school board may appoint such medical inspectors as may be necessary.

Dogs (Injuries to Persons) Bill.

Mr. DUNDAS WHITE'S Bill to amend the law relating to injuries to persons by dogs has the support of Mr. CHOMRE, Dr. SHEPHERD, Lord ROBERT CRUICK, Sir JOHN JARDINE, Mr. T. F. RICHARDS, Mr. ARNOLD HERBERT, and Mr. MOLTENO. As the law now stands a person who is injured by a dog cannot recover damages from the owner of the dog unless, in addition to proving the damage, he can also prove the "scienter," that the dog was known to be dangerous. This frequently deprives the injured person from a remedy. The Bill is designed to place the risk on the owner of the dog, who can control its movements, instead of on the injured person who cannot, with a view to making dog owners more careful, and so not only securing compensation for, but also obviating, such injuries.

The Accounts of the General Medical Council.

The accounts of the General Medical Council and branch councils and of the Dental Registration Fund for 1906 have been presented to Parliament.

HOUSE OF COMMONS.

WEDNESDAY, MARCH 27TH.

The Inspection of Vitiolation Experiments.

Mr. SKEATON asked the Secretary of State for the Home Department what were the salaries paid to the English inspectors of vitiolation, Mr. Thane and Sir James Russell; whether out of 2506 operation experiments made last year, only 15 were witnessed by the senior inspector; whether the Home Office granted vitiolation licences on the recommendation of the Research Association; and whether this association existed for the protection and promotion of vitiolation.—Mr. GLANVILLE said, in reply: The remuneration of the inspector under the Cruelty to Animals Act, 1876, is 500 guineas, and that of the assistant inspector is 350 guineas. The number of operation experiments witnessed by Mr. Thane in 1905 was 15. The number was smaller than usual in consequence of the inspector being absent on sick leave for some weeks. Among the objects of the Association for the Advancement of Medicine by Research are the protection of the interests of

licences and the publication of literature on the importance of research. Applications for licences and new certificates are sent to the association for observations; but the Secretary of State forms his own opinion in each case after considering the reports of his own expert advisers, and the responsibility rests with him.

Military Doctors and Civilian Casualties.

Mr. MARYHAM asked the Secretary of State for War whether his attention had been called to a serious, and afterwards fatal, accident to the driver of a London and South-Western Railway motor train near Bentley Station on Feb. 23rd, when the injured man was taken by train to Bordon Camp, with a view to his receiving the assistance of the military doctor there; whether he was aware that the latter refused to attend to the man; whether there were any restrictions in the Army Regulations which prevented military officers from attending to civilian casualties such as the one referred to; and, if so, would he take steps to have such restrictions forthwith removed.—Mr. HALSEY answered: I have made inquiries into this matter. It appears that the military medical officer concerned was not asked to attend to the man. There are no restrictions placed on military medical officers against rendering immediate assistance in civil cases, nor to the admission into military hospitals of cases requiring surgical attendance the result of serious accidents in the immediate vicinity.

Vivisection Experiments.

Answering Mr. SKEATON, Mr. GLADSTONE said that he hoped the return of the vivisection experiments performed during the past year would be issued during May.

Illness and Vaccination.

Mr. LUTON asked the President of the Local Government Board whether Dr. Fletcher was paid for reporting on cases of illness following vaccination; whether formerly similar reports were published; and on what ground of public policy such reports were kept secret notwithstanding the wish of the parents for publicity.—Mr. JOHN BURNS replied: Dr. Fletcher is one of the medical inspectors of the Local Government Board and is paid an annual salary for the discharge of his duties, which, like those of other medical inspectors, include the occasional investigation of cases of illness alleged to be due to vaccination. Some of the reports of the inspectors were communicated to the Royal Commission on Vaccination and the facts contained in certain of these reports were published by them, but since the final report of the Commission no further reports of the kind in question have been published. The reports of necessity often deal with the acts of family history of individuals and must, I think, be treated as confidential.

Whooping-cough at Norwood.

Mr. LEWIS HASLAM asked the President of the Local Government Board whether he would state how many children in the Lambeth Poor-law school at Norwood had been, and were at present, affected by the recent outbreak at that school of diphtheria, scarlet fever, and whooping-cough respectively; and whether any cases had as yet been fatal.—Mr. BURNS said in reply: My honourable friend is, I think, under a misapprehension in this matter. I understand that with the exception of six mild cases of whooping-cough, five of whom are convalescent, there has been no recent outbreak of the diseases mentioned in the question at the school, nor has there been any death from them. At present there is not a single case of diphtheria or scarlet fever in the school.

Pot-still and Patent-still Whiskies.

Mr. H. O. LEA asked the Chancellor of the Exchequer whether the Inland Revenue officials did not discriminate in their accounts between pot-still and patent-still whisky, the distilleries being in almost all cases distinct; and whether, in view of the importance to the wholesale spirit trade in this country that this information should be given to the public, he could state the quantities of pot-still and patent-still whiskies produced in England, Ireland, and Scotland in the years 1888, 1896, and 1906 respectively; and, if it was impossible to furnish this information for the past, would he issue orders for the facts to be ascertained and circulated in future.—Mr. ASQUITH said: No discrimination is at present made between pot-still and patent-still spirit and consequently no departmental records exist from which a return of the kind named could be made for past years. If legislative authority were given, it would be possible for the department to keep a record in the future of the quantities of spirit distilled by pot-stills and patent stills respectively; but such a record would afford no evidence of the relative quantities used for potable and other purposes. Still less would it afford evidence of the relative quantities used for a particular spirit, such as whisky and other potable spirits, for the total product of patent stills is applied only partly to the purposes of "drinking" spirits, and the distribution of such part as is so applied between the several classes of potable spirits, gin, whisky, compounds, &c., cannot be determined.

Tests for Colour Blindness.

Mr. HENRIKER HEATON asked the President of the Board of Trade whether he had any official information showing that the tests for colour blindness adopted by the Board of Trade were efficient.—Mr. LORD GEORGE (in a written answer) replied: I can only say that the colour tests for the Mercantile Marine were adopted on the advice of a committee of the Royal Society of the highest eminence, and that the Board of Trade has no reason to doubt their efficiency.

A Death from Privation.

Mr. SUMMERBELL asked the Secretary of State for the Home Department whether his attention had been called to the case of Ellen Simpson, who was shown at the inquest held as to her death at Stepney on March 16th last to have died from heart failure accelerated by want; and, if so, whether any relieving officer or other officer of the Stepney guardians was present at the inquest and at what date would particulars of this inquest be sent to the Local Government Board by the Home Office.—Mr. GLADSTONE (in a written answer) replied: I understand that the deceased and her sister had been refused outdoor relief and that they declined to go into the workhouse. They appear to have been unable to look after themselves. No relieving officer was examined at the inquest; the woman had been in the district only a few days and no relieving officer unfortunately knew anything of the case. Particulars of deaths from starvation or deaths accelerated by privation in 1907 will be furnished about March next and sent to the

Local Government Board. I am bringing the case to the notice of the Local Government Board.

Housing in Roscrea.

In answer to Mr. KENDAL O'BRIEN, Mr. BIRRELL, in a written reply, stated that the Irish Local Government Board had received application from the Roscrea rural district council for carrying out a housing scheme under the Housing of the Working Classes Act, 1901. Rural district councils could only exercise the powers under Part II of the Act which related primarily to the closing and demolition of buildings unfit for human habitation and to the removal of obstructive buildings.

Sewage Disposal.

Sir FREDERICK BANBURY asked the President of the Local Government Board whether it was the intention of the Government to introduce a Bill dealing with the recommendations of the Royal Commission on Sewage Disposal.—Mr. JOHN BURNS (in written answer) replied: The matter is under consideration but I cannot make any announcement with regard to it at the present moment.

BOOKS, ETC., RECEIVED.

Appointments.

Useful applicants for Vaccinator, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to THE LANCET Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week such information for gratuitous publication.

ALAN, JOHN, M.B., Ch.B. Edin., has been appointed Senior House Surgeon to the Walsall and District Hospital, Walsall.

APES, ROBERT, M.R.C.S. Eng., L.R.C.P. Lond., has been appointed Medical Officer to the Camberwell Provident Dispensary.

BAILE, JOSEPH ALEXANDER, M.B. Lond., M.R.C.S. Eng., L.R.C.P. Lond., has been appointed Consulting Physician to the Pembroke and District Infirmary.

EDIN, EDWARD A., B.Sc., M.B., Ch.B. Edin., has been appointed Senior House Surgeon at the Blackburn and East Lancashire Infirmary.

EMILL, J. M., M.B., B.Sc. Lond., has been appointed an Assistant Inspector of Foods in the Medical Department of the Local Government Board.

ETWARD, W. CURLING, M.B., B.S. Durh., M.R.C.S., L.R.C.P. Lond., has been appointed Principal Medical Officer and Director of the Egyptian Government Hospital, Port Said.

DOVER, ALFRED SYMON, M.R.C.S., L.R.C.P. Lond., has been appointed Senior Resident Medical Officer to the Royal Hospital for Diseases of the Chest, City road, E.C.

WILLIAMS, J. S., M.R.C.S., L.R.C.P. Lond., has been appointed Certifying Surgeon under the Factory and Workshop Act for the Tetbury District of the county of Gloucester.

SMITH, WILLIAM, M.R.C.S., L.S.A. has been appointed Medical Officer of Health for Liskeard (Cornwall).

PIZZALI, J. A. WENCESLAUS, M.D. Brux., M.R.C.S. Eng., L.R.C.P. Lond., has been appointed Honorary Surgeon to the Exeter Dispensary.

PLIGHT, CHARLES T. MACL., M.B., B.C. Cantab., M.R.C.S., L.R.C.P., has been elected Honorary Surgeon to the West Norfolk and Lynn Hospital.

ROSE, H. S., M.B., B.C. Cantab., has been re-appointed Medical Officer to the Bridgewater Union.

ROYLE, JOSEPH M., M.R.C.S., L.R.C.P. Lond., has been appointed Junior House Surgeon at the Blackburn and East Lancashire Infirmary.

PELLEY, BINGLEY GIBBS, M.R.C.S., L.S.A., has been appointed Medical Officer for Sidmouth (Devon).

REYNOLDS, S. H., M.B., C.M. Edin., has been appointed Clinical Assistant to the Chelsea Hospital for Women.

SMITH, A. W. PORTESCUE, M.D. Brux., L.R.C.P. Lond., M.R.C.S., D.P.H. Lond., has been appointed Surgeon to the Exeter Dispensary.

SCOTT, STOKER R., M.B., M.S. Lond., F.R.C.S. Eng., has been appointed Aural Surgeon to the Evelina Hospital for Sick Children.

SMITH, S. MAYNARD, M.B., B.S. Lond., F.R.C.S. Eng., has been appointed Assistant Surgeon to the Victoria Hospital for Children.

TAPP, B. H. H., M.R.C.S., L.R.C.P. Lond., has been appointed Certifying Surgeon under the Factory and Workshop Act for the Southwold District of the county of Suffolk.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index)

ANTON-UNDER-LYNE DISTRICT INFIRMARY.—Junior House Surgeon. Salary at rate of £75 per annum, with board, attendance, washing, &c.

The Chief Inspector of Factories, Home Office, S.W., gives notice of a vacancy as Certifying Surgeon under the Factory and Workshop Act at Llanwrtyd Wells, in the county of Brecknock.

Births, Marriages, and Deaths.

BIRTHS.

UNDERHILL.—On March 27th, at San Remo, Heme Hill, the wife of Thomas Hill Underhill, M.B., M.Ch., of a daughter.

UPCOTT.—On March 27th, at Leeds, the wife of Harold Upcott, F.R.C.S., of a son.

MARRIAGE.

MARJORIBANKS-SIMCOX.—On March 14th, at St. Thomas' Cathedral, Brompton, Captain J. L. Marjoribanks, M.S., to Elizabeth Homphray, daughter of the late Rev. H. K. Simcox.

DEATHS.

CHARLES.—At Ince, Swansea, on March 5th, Henry Evans Charles, M.R.C.S. Eng.

PHILLIPS.—On March 27th, at 33, Albany Villas, Hove, after a few days' illness, Lawrence William Kingslake Phillips, M.D., second son of Barclay Phillips of 7, Harpur-park, Edin.

Notes, Short Comments, and Answers to Correspondents.

A RETIRED MEDICAL MAN AND GOOD OPENINGS.

We publish below a communication from Dr. Jay, who tells us in his covering letter that he is "prepared for a fair fight," adding "If you suppress my reply I shall be compelled to seek another channel." The references to a fair fight and to suppression are due to the fact that we have previously received letters from Dr. Jay of a scurrilous nature, which we have refused to publish, not because we have the slightest objection to our readers knowing Dr. Jay's bad opinion of us, but because our morals are not now in question. The letter below contains what the other ones did not, an explanation of Dr. Jay's procedure; it is therefore inserted with pleasure and Dr. Jay can publish it also through any other channel which he thinks fit.

To the Editors of THE LANCET.

SIRS,—Having disposed of my practice in Faversham some months since I inserted, the following advertisement in one daily and two weekly papers:—

Small HOUSE wanted in the country with garden, within 25 miles of the City, not far from a railway station, and where a medical man would be appreciated. Send rent and particulars to Betta, 6, Stone St., Faversham.

I had a hundred replies at least from medical men, builders, house agents, auctioneers, surveyors, and private individuals residing within the distance I named, as well as many beyond. I should say that 20 or more, owing to a phenomenal increase of population and other causes, offered an excellent chance for starting in practice without interfering with the rights or vested interests, as I suppose you would call them, of men already upon the spot, many of whom had themselves started without purchase. That we have a right to go where we like to practise cannot be disputed, even should it be in Harley-street. The risk is with us, and it is utter nonsense to say in these days, when the profession is overcrowded and many men without the means to purchase, that a man is not to make a start for himself. With this in my mind, I have placed before young doctors some of the opportunities which presented themselves, for which I have received many letters of thanks. I have visited and investigated the possibilities of success which has been attended with expense, and by charging a nominal premium I try to recoup myself.

I repeated my advertisement with a still wider scope in my own interest, as I had a desire to settle again in the Eastern Counties, when I received more replies than in the first instance. Some were from populous villages with no doctor within five miles and several villages around similarly situated, begging me to take up residence with them. You will perceive I had no occasion to attempt to call No. 369 to No. 368, as you suggest, and which I defy you to prove I have attempted to do. I replied to No. 369 upon my own behalf, thinking it might suit me, but have not offered it to anyone with a view to profit. I had no occasion to do so, my desk being strewn with better things.

Your discharge of a public duty, as you term it, has, in this instance, been accompanied by an unpleasant seat upon a "mare's nest."

I think I am entitled to an ample apology for the attack you have made upon me. I ignore the title of people who have never been in practice to dictate rules of conduct for medical practitioners and so express them as to bring medical men into disrepute with their neighbours. Your method seems to be suggestive. I fail to find that you have proved a single instance of unprofessional conduct. Random accusations have no legal value.

Yours truly,

F. FITZGERBERT JAY.

Faversham, April 2nd, 1907.

We disapprove of Dr. Jay's method and of the use to which he has put our advertisement columns. We shall take what steps we can to provide that the latter do not offer him further opportunities.

ZAM-BUK.

To the Editors of THE LANCET.

SIRS,—Something really ought to be done re the sale of "quack" remedies such as the above. A woman in this village was advised by a neighbour to apply some "Zam-buk" for a sprained muscle. A painful vesicular eruption has been the result over the whole area where applied, and now the whole body is covered with a painful irritable rash. The constitutional symptoms are pronounced, fainting attacks being the most important, with general prostration. I know of another victim, but conclude that the present case is as good an example as any for the purpose in view.

I am, Sirs, yours faithfully,

FRANCIS G. BENNETT.

Great Glenn, Leicester, March, 31st, 1907.

obtained from various members of the natural order Papaver. Protopine is mentioned in Merck's list, dated November, 1895, as "Protopin, pure, precipitated from opium"; no price is quoted. According to Cushman's "Text-Book of Pharmacology," 10th edition, protopine differs from morphine in its pharmacological action. In frogs small doses produce a narcotic condition due to that following the injection of morphine, but the irritability does not show the same exaggeration afterwards; in doses cause complete paralysis of the whole central nervous system. In mammals no depression occurs, but the administration of protopine is followed by restlessness and eventually by convulsions which not seem to be of spinal origin but rather suggest a stimulation of the cerebrum and mid-brain. The heart is slow and weak and in doses of the drug cause some depression of the vaso-motor center. The respiration appears to be accelerated, except by large doses of protopine. A further difference between the action of morphine and protopine is found in the marked action of the latter on striated muscles, which subsequently react to electric shocks by a series of rapid contractions and relaxations, no real tetanus being produced. A fairly thorough search through the literature has not elicited further information concerning protopine.

H. E. C.—We understand that if the husband brought a suit, not divorce but for annulment of the marriage, in all probability a court would order the wife to submit to inspection and on refusal would assume her incapacity and make a decree of nullity. The matter is, however, as our correspondent says, a purely legal one, and the man in question should certainly obtain legal advice.

ETHICS.—The General Medical Council forbids the employment of unqualified assistants, except when they work directly under the employer's eye, for instance, as a pupil or as assistant in a surgery. If the facts are as our correspondent states, A is contravening the order of the General Medical Council.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

Medical Diary for the ensuing Week

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY (8th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (2 P.M.), St. Mary's (2.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynaecological, by Physiological, 2 P.M.), Soho-square (2 P.M.), City Orthopaedic (4 P.M.), St. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (9.30 A.M.), Royal Free (2 P.M.), Guy's (1.30 P.M.), Children, Gt. Ormond-street (3 P.M.), St. Mark's (2.30 P.M.).

TUESDAY (9th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), West London (2.30 P.M.), University College (2 P.M.), St. George's (2 P.M.), St. Mary's (1 P.M.), St. Mark's (2 P.M.), Cancer (2 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), Soho-square (2 P.M.), Chelsea (2 P.M.), Central London Throat and Ear (2 P.M.), Children, Gt. Ormond-street (2 P.M.), Ophthalmic, 2.15 P.M.), Tottenham (2.30 P.M.).

WEDNESDAY (10th).—St. Bartholomew's (1.30 P.M.), University College (2 P.M.), Royal Free (2 P.M.), Middlesex (1.30 P.M.), Charing Cross (3 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), King's College (2 P.M.), St. George's (Ophthalmic, 1 P.M.), St. Mary's (2 P.M.), Samaritan (National Orthopaedic (10 A.M.), St. Peter's (2.30 P.M.), West (9.30 A.M. and 2.30 P.M.), Gt. Northern Central (2.30 P.M.), Westminster (2 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Cancer (2 P.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Royal Free (2 P.M.), Royal Orthopaedic (3 P.M.), Children, Gt. Ormond-street (9.30 A.M., Dental, 2 P.M.), Tottenham (Ophthalmic, 2.30 P.M.).

THURSDAY (11th).—St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), University College (2 P.M.), Charing Cross (3 P.M.), St. George's (1 P.M.), London (2 P.M.), King's College (2 P.M.), Middlesex (1.30 P.M.), St. Mary's (2.30 P.M.), Soho-square (2 P.M.), North-West (1.30 P.M.), St. Mark's (2 P.M.), Gt. Northern Central (Gynaecological, 2.30 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (Metropolitan (2.30 P.M.), Throat, Golden-square (9.30 A.M.), Guy's (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), Children, (1.30 P.M.), Royal Orthopaedic (9 A.M.), Royal Free (2 P.M.), Children, Gt. Ormond-street (2.30 P.M.), Tottenham (Gynaecological, 1.30 P.M.), St. Peter's (2 P.M.).

FRIDAY (12th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Charing Cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), St. Mary's (2.30 P.M.), Ophthalmic (10 A.M.), Cancer (2 P.M.), Chelsea (2 P.M.), St. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (3.30 A.M.), City Orthopaedic (2.30 P.M.), Soho-square (9.30 A.M.), Golden-square (9.30 A.M.), Throat, Golden-square (9.30 A.M.), Children, Gt. Ormond-street (9 A.M., Aural, 2 P.M.), Tottenham (2.30 P.M.), St. Peter's (2 P.M.).

SATURDAY (13th).—Royal Free (9 A.M.), London (2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), University College (9.15 A.M.), Charing Cross (2 P.M.), St. George's (1 P.M.), St. Mary's (10 P.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Children, Gt. Ormond-street (9.30 A.M.), the Royal London Ophthalmic at the Royal Eye Hospital (2 P.M.), Ophthalmic (1.30 P.M.), and the (10 A.M.), the Royal Westminster Ophthalmic operations are performed daily. Central London phthimic Hospitals operations are performed daily.

SOCIETIES.

MONDAY (8th).—MEDICAL SOCIETY OF LONDON (11, Chandos-street, Cavendish-square, W.).—8 P.M.: Clinical Meeting. Cases will be exhibited by Dr. Chapman, Dr. Parkinson, Dr. Voelcker, Dr. Poynton, Dr. P. Weber, Dr. Clutterbuck, Mr. J. M. Donagh, and others.

Enquirer.—Protopine was discovered in 1871 by Hesse in opium, but it has since been found in a large number of other plants, including most plants of the widely distributed natural order Papaveraceae and *Argemone Mexicana*. At first the identity of the alkaloid obtained from these different sources was not recognised, hence it was known as "argemoneine" when prepared from argemone and as "fumarine" when

THURSDAY (5th).—ROYAL MEDICAL AND CHIRURGICAL SOCIETY (20, Hanover-square, W.).—8.30 P.M.: Major L. Rogers, I.M.S.: (1) The Early Diagnosis and Cure of the Fre suppurative Stage of Amebic Hepatitis, (2) A Common Sporadic Seven day Fever of Indian Ports simulating Dengue.

WEDNESDAY (6th).—BRITISH BALNEOLOGICAL AND CLIMATOLOGICAL SOCIETY (20, Hanover-square, W.).—5.30 P.M.: Adjourned Discussion on the Present Position of the Treatment of Tuberculosis by Marine Climates (opened by Dr. A. Street, Westgate-on-Sea). Paper:—Dr. N. H. Forbes: Church Stretton as a Health Resort.

DERMATOLOGICAL SOCIETY OF LONDON (11, Chandos-street, Cavendish-square, W.).—5.15 P.M.: Meeting.

HISTORICAL SOCIETY (London Institution, Finsbury-circus, E.C.).—8.30 P.M.: Discussion on Epilepsy. First Evening: Dr. F. Beach (Historical), Dr. G. Holmes (Pathology), Dr. P. Stewart (Masked Epilepsy), Dr. Mercier (Epileptic Insanity).

TUESDAY (11th).—BRITISH GYNECOLOGICAL SOCIETY (20, Hanover-square, W.).—8 P.M.: Specimens will be shown by Mr. B. Jessett and Dr. Swanton. Paper:—Prof. Jacobs (Brussels): The Radical Cure of Prolapsus Uteri.

WEDNESDAY (12th).—WIMBLEDON AND DISTRICT MEDICAL SOCIETY (Worple Hall, Worple-road, Wimbledon).—9 P.M.: Paper:—Mr. H. Tilley: The Diagnosis and Treatment of Certain Nasal Diseases frequently met with in General Practice.

CLINICAL SOCIETY OF LONDON (20, Hanover-square, W.).—8.30 P.M.: Papers.—Mr. G. H. Makins and Mr. P. Sargent: A Note on the Value of Anti-colon Bacillus Serum.—Mr. L. McGavin: A Modification of the Method of applying Prepared Filigree of Silver Wire to the Cure of Large Inguinal Hernia in Males.—Mr. W. G. Spencer: Acute Solitary Suppuration in the Psoas and Iliacus Muscles.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

MONDAY (8th).—POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.).—2 P.M.: Medical and Surgical Clinics. X Rays. Mr. Dunn: Diseases of the Eye. 2.30 P.M.: Operations.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chancery-street, W.C.).—4 P.M.: College re-opens.

NORTH-EAST LONDON POST-GRADUATE COLLEGE (Tottenham Hospital, N.).—Cliniques.—9.30 A.M.: Surgical Out-patient (Mr. H. Evans). 2.30 P.M.: Medical Out-patient (Dr. Whipple), Throat, Nose, and Ear (Mr. Carson), X Ray (Dr. Pirle).

TUESDAY (9th).—POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.).—10 A.M.: Dr. Moullin: Gynecological Operations. 2 P.M.: Medical and Surgical Clinics. X Rays. Dr. Ball: Diseases of the Throat, Nose, and Ear. 2.30 P.M.: Operations. Dr. Abraham: Diseases of the Skin.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chancery-street, W.C.).—4 P.M.: Dr. H. Campbell: Clinique. (Medical). 6.15 P.M.: Lecture.—Dr. T. Williams: Laenneo and the Evolution of the Stethoscope.

NORTH-EAST LONDON POST-GRADUATE COLLEGE (Tottenham Hospital, N.).—Cliniques.—10.30 A.M.: Medical Out-patient (Dr. Auld). 2.30 P.M.: Gynecological Out-patient (Dr. Gilles), Surgical Out-patient (Mr. Edmunds). Surgical Operations (Mr. Carson). Demonstration on Fevers (Dr. F. Thomson at the North-Eastern Fever Hospital, St. Ann's-road, N.W.).

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chancery-street, W.C.).—4 P.M.: Mr. J. Clarke: Clinique. (Surgical). 6.15 P.M.: Lecture.—Dr. N. Tizard: Some Recent Cases of Hematuria.

NORTH-EAST LONDON POST-GRADUATE COLLEGE (Tottenham Hospital, N.).—Cliniques.—2.30 P.M.: Skin (Dr. Meachen), Eye (Mr. Brooks), Medical Out-patient (Dr. Whipple).

CENTRAL LONDON THROAT AND EAR HOSPITAL (Gray's Inn-road, W.C.).—5 P.M.: Demonstration.—Mr. J. Atkinson: External Ear.

THURSDAY (11th).—POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.).—2 P.M.: Medical and Surgical Clinics. X Rays. Mr. Dunn: Diseases of the Eye. 2.30 P.M.: Operations.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chancery-street, W.C.).—4 P.M.: Mr. Hutchingson: Clinique. (Surgical). 6.15 P.M.: Lecture.—Mr. M. Morris: The Treatment of Some Common Skin Affections.

NORTH-EAST LONDON POST-GRADUATE COLLEGE (Tottenham Hospital, N.).—2.30 P.M.: Gynecological Operations (Dr. Gilles). Cliniques.—Medical Out-patient (Dr. Whiting), Surgical Out-patient (Mr. Carson), 3 P.M.: Medical in patient (Dr. Chappel).

FRIDAY (12th).—POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.).—10 A.M.: Dr. Moullin: Gynecological Operations. 2 P.M.: Medical and Surgical Clinics. Dr. Ball: Diseases of the Throat, Nose, and Ear. X Rays. 2.30 P.M.: Operations. Dr. Abraham: Diseases of the Skin.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chancery-street, W.C.).—4 P.M.: Mr. S. Stephenson: Clinique. (Eye).

NORTH-EAST LONDON POST-GRADUATE COLLEGE (Tottenham Hospital, N.).—9.30 A.M.: Clinique.—Surgical Out-patient (Mr. H. Evans). 2.30 P.M.: Surgical Operations (Mr. Edmunds). Cliniques.—Medical Out-patient (Dr. Auld), Eye (Mr. Brooks). 3 P.M.: Medical in patient (Dr. Leslie).

SATURDAY (13th).—POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.).—10 A.M.: Dr. Ball: Diseases of the Throat, Nose, and Ear. 2 P.M.: Medical and Surgical Clinics. X Rays. 2.30 P.M.: Operations.

EDITORIAL NOTICES.

It is most important that communications relating to the Editorial business of THE LANCET should be addressed exclusively "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring

under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET should be addressed "To the Manager."

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newspapers (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and not to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will insure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.				TO THE COLONIES AND ABROAD.			
One Year	...	...	£1 12 6	One Year	...	...	£1 14 8
Six Months	...	...	0 18 3	Six Months	...	...	0 17 4
Three Months	...	...	0 8 2	Three Months	...	...	0 8 8

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOON, THE LANCET Offices, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates, on this or on any other ground, should be resisted. The Proprietors of THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues; and Agents are authorised to collect, and generally do so collect, from the Proprietors the cost of such extra postage.

METEOROLOGICAL READINGS.

The Kumbleian Lectures

ON

THE INCREASE OF INSANITY.

Delivered before the Royal College of Physicians of London on
March 14th, 19th, and 21st.

By G. H. SAVAGE, M.D. LOND.,
F.R.C.P. LOND.,

CONSULTING PHYSICIAN FOR, AND LATE LECTURER ON, MENTAL
DISEASES, GUY'S HOSPITAL; CONSULTING PHYSICIAN TO
THE IDIOT ASYLUM, EARLSWOOD.

LECTURE III.¹

Delivered on March 21st.

MR. PRESIDENT, FELLOWS, AND GENTLEMEN,—The next generally accepted cause of insanity is alcoholic intemperance. That this is a potent cause, not only of actual insanity but of nervous weakness and instability in the individual and in his offspring, must be admitted. And there is a generally accepted belief that the character of the alcohol taken to a certain extent affects the results, so that those who consume the more potent alcoholic liquids suffer most nervously. It was till quite recently looked upon as an established fact that with higher wages and the increased consumption of alcohol, especially in its stronger forms, there was a definite increase in the pauper insane. This may have been true, but, as I shall point out later, the increase of insanity at the present time certainly bears no actual relationship to the consumption of alcohol. There is no doubt whatever that the people in England at present are far more temperate than they were. The returns as to the consumption of all forms of alcohol show the marked reduction in the consumption, and this probably is more marked in the lower middle and lower classes than among the higher classes. One would therefore have expected, if there is a direct relationship between the consumption of alcohol and mental unsoundness, that there would have been a reduction rather than an increase of insanity at present. But, as I have said, this is not the fact. It is always dangerous to come rapidly to conclusions on comparatively slight statistics or general information. But I am bound to say that the very large number of total abstainers whom I see in consulting practice has made me wonder whether the complete and total change from moderate indulgence in alcohol to total abstinence had been altogether for the good, the mental good I may say, of the race. It is well, however, to remember that a certain proportion of total abstainers are the descendants of alcoholic parents who, having seen the disastrous results of excess in a parent, have determined at once to refrain altogether. Such individuals have already a weakened nervous system by inheritance, and therefore that they should become abnormally sensitive and tend to melancholy is not surprising. There are others who are total abstainers not having strength of will to be moderate. Such people are predisposed to break down mentally if unusual strain is thrown upon them. It is interesting to note that in Ireland, where certainly a considerable amount of alcohol is consumed, the medical superintendents of many of the asylums report that, next to heredity, they look upon alcoholic excess as the chief cause of insanity; a second cause is given by a large number of the superintendents—excess of tea drinking. I am hardly prepared to accept this as a cause, yet it is right that I should mention it. There is no doubt that excess of alcoholic stimulants leads to direct alteration in the nutrition of the brain and nervous system, and also that, if the induced recurring alteration occurs, there will be permanent nutritional changes which become visible in the whole nervous system. And these changes give rise to corresponding mental symptoms. Thus the peripheral neuritis which is frequent in cases of chronic alcoholism not seldom gives rise to cutaneous hallucinations; and gastrointestinal trouble produced from the same cause may also give rise to delusions. Thus, as a result of peripheral neuritis, chiefly affecting the limbs, it is a common experience to meet with patients—and I think I might say more commonly women—who complain that they are annoyed,

electrified, or interfered with as far as their skin was concerned, by some systematic persecution. In the second group one not infrequently meets with gastric alcoholics who accuse persons of tampering with their food. It will thus be seen how readily delusions and hallucinations of the senses may be the direct outcome of chronic alcoholism. Continued excess leads to premature degeneration of the brain. Thus on one hand we have symptoms allied to delirium similar to those produced by general toxic influences, while on the other we have symptoms of premature senility. And the whole group of symptoms, which have been described more recently under the name of Korsakow's syndrome, depend almost invariably on toxic influences and are most marked in alcoholic cases and in senility with mental decay; and Metchnikoff has described toxins which he believes to be associated with senility. And it is interesting to recognise that this group of symptoms is constantly met with, not only in the toxic conditions I have referred to, but also in senility. We have therefore alcohol producing a definite set of symptoms, and I say that any mental disorder which may be produced temporarily may, if the toxic influence is continued, become established as a morbid habit, associated with organic change. I have also pointed out that chronic alcoholism leads to something more than mere toxic changes, to permanent decay of the whole nervous system.

The next, and a most important, question, especially in relationship to the increase in insanity, is the fact that alcoholic parents tend to have degenerate children. The children of chronic alcoholics have most of the characteristics of the children of the highly neurotic or the degenerately insane; idiocy, imbecility, and moral insanity being most marked in the children of the chronic alcoholic. Dr. F. W. Mott recently published some very important observations in relationship to alcoholism and nervous disorder. Similar observations were recorded by Mr. W. Bevan Lewis. And I would sum up their results as follows. Dr. Mott considered that one-fourth of the out-patients whom he saw at Charing Cross Hospital had alcohol as an efficient or coefficient in causing the bodily disease for which he was consulted. He believed that the grocer's licence tended to drinking among women, which produced many of the polyneuritic neuroses. Dr. Mott goes so far as to say that he is of opinion that there is no proof that insanity itself would diminish to anything like the extent that is believed by many enthusiasts if alcohol were altogether abolished, and I have already said the same. Next follows the startling statement that the people who were in general hospitals and who consulted him in the out-patient room as a result of alcoholic excess, generally had visceral disease of some kind: that they had kidney disease, or liver disease, or some polyneuritis. On the other hand, at the asylum he found that those patients who were admitted suffering from the insanity of alcoholic excess rarely, if ever, had the pathological signs generally associated with alcoholic excess. So that the post-mortem examinations of the insane from alcohol rarely provided cirrhotic liver or contracted kidneys. Various interpretations may be given to this. One is that some people are predisposed to be affected by alcohol along their digestive tracts, whereas others are more affected along the nerve lines. Others have thought that when one system was affected, whatever the cause might be, the other would be free, and that, in fact, the old belief was true, that if a man had a bodily disease he would not have a mental one, or if he had a mental one he would not have a bodily one. The interpretation which I believe Dr. Mott prefers is this: that the people who become insane as a result of alcohol require quite a small amount of alcohol to upset their balance in comparison with others: that, in fact, they may be compared to those persons who, having had some severe head injury, ever afterwards are predisposed to be easily affected by alcohol. The fact, however, is an important one, and although one has not time to consider the question of alcoholism as written about by Dr. A. Reid, yet one has to recognise that there is such a thing as the survival of some alcoholics.

Having referred to the effect of alcohol in the production of insanity it is necessary to refer to the effects of alcohol when added to other causal conditions. I have very little evidence indeed to support the contention that general paralysis of the insane depends to any extent upon alcoholic excess alone. My own experience leads me to believe that from 70 to 80 per cent. of the cases of general paralysis which I see have suffered from syphilis. But in nearly all

¹ Lectures I. and II. were published in THE LANCET of March 30th (p. 555) and April 13th (p. 533) respectively.
No. 4363.

these cases I should say that the patients had led exciting, trying lives, that they were people who had indulged freely in alcohol and, as a rule, were large meat eaters. So that alcohol, when added to syphilis and to other abnormal or exciting conditions, may be considered as one of the causes of general paralysis of the insane. I add the notes now from the Commissioners in Lunacy in Ireland in relationship to alcohol as a cause of insanity.

ALCOHOLIC EXCESS.

General.—The proportion attributed to alcohol underwent some fluctuations during the decade but in 1903 it was only 0·8 per cent. higher than in 1894.

Perhaps as regards its effects on the future prosperity and health of the population the most important of these causes is intemperance in the use of alcohol.

As already stated, these statistics show that alcohol was found to have been the principal cause of the outbreak of mental disease in 15 per cent. of the cases admitted to asylums during the decade under review. This does not differ materially from the proportion in earlier years.

Page 2.—Alcohol is, no doubt, a frequent cause of mental breakdown. It is difficult to differentiate as to whether it is more frequently a cause or that excessive indulgence is a result of mental weakness or instability. (Lawless.)

Page 4.—Alcohol is an increasing factor in the causation of insanity, both by its acute and chronic toxic effect. (Mills.)

Page 13.—Alcohol is often suggested as being a fruitful cause, but my experience would not justify such a conclusion with regard to it. Undoubtedly the drink sold at fairs and markets is of the worst kind and must have an injurious effect on those who indulge in it; still, it may be fairly claimed for the female population of the district, and especially those residing in the country villages, that only very rarely indeed do they ever taste intoxicants. So rarely that I would be inclined to eliminate this as a cause of the insanity among them. (Hatchell.)

Page 23.—In close on 9 per cent. of the cases admitted there was the strongest possible evidence that alcohol was the main cause of the evil. (Nolan.)

Page 39.—I am of opinion that the next greatest cause of insanity is drink, and by this I mean not only persons become insane by drinking to excess but also that many of the children of confirmed drunkards who are saturated with alcohol become weak-minded or insane. (West.)

Page 45.—Either drinking still exists in this district but to a much less degree of late. (Hetherington.)

Page 61.—The most frequent causes will be seen to be hereditary predisposition and alcoholic excesses. (Oakshott.)

Many years since, when the first of recent epidemics of influenza appeared, certain medical journals pointed out what seemed to be the immunity from this disease of the insane in asylums; but it was soon made manifest that the attendants and nurses who went into the outer world contracted the disease, and when once it was started in an asylum it spread as rapidly as it did elsewhere. I pointed out, on the other hand, that it was a very powerful starting point for neuroses, and it is now pretty generally accepted that it predisposes to such neuroses and may be either a predisposing or exciting cause. I believe that it has been a real and efficient cause for inducing any increase which now exists, and I believe from my personal experience that it is and has been more powerful than all the other causes put together. I fear that I shall not have time to do more than point out the effect which influenza has had generally on the production of nervous disorders of various kinds. In the first place it is a constant cause of most obstinate insomnia; and as food and digestion are to the body, so is sleep to the whole nervous system. It causes painful neuralgias and often disturbs digestion and nutrition.

But from these general statements I pass to the more concrete and definite ones. Influenza, like other fevers, may set up any form of psychopathy. Morbid mental symptoms may come on at any period of the influenza; it may start any form of insanity. Thus, the febrile stage may be followed by acute delirious mania of the worst possible type or it may give rise to sleeplessness with melancholia, either of an active or passive kind. It may lead directly to dementia either of a permanent or transient type. There is, however, no specific form of insanity which can be called influenzal. I believe influenza produces effects on the nervous system comparable with those depending on strong neurotic heredity or alcoholic or senile degeneration. Therefore, after several attacks of influenza it is not uncommon for fully organised delusional insanity, with grandiose ideas or ideas of persecution, to appear. In patients with strong neurotic heredity the first attack of insanity often follows influenza. In patients who have had previous attacks of insanity influenza may start a fresh attack, which may or may not follow the course of previous attacks. The mental disorder need have no relation to the severity of the attack of influenza. Though not a cause of general paralysis of the insane, yet it may be the exciting

cause, so that a person who has other causes of degeneration, such as syphilis and alcohol, after an attack of influenza may rapidly develop all the symptoms of general paralysis of the insane. In a few instances I have seen attack of influenza modify an attack of insanity, and relieve it. It is noteworthy that suicides increase markedly after an epidemic of influenza.

While fully recognising that the time at my disposal only allow me the opportunity of bringing before you most potent causes of mental instability and those which I think may, to a certain extent, be looked upon as causes of any increase of insanity which is found to exist, I feel I must consider the question of sexual morality. I do believe the present time is much better, or much worse, than the past, but there are certain considerations which I believe to be important and to which I now refer. Marriages in England at all events, less frequent than they were and men certainly it is common for the marriages to take place at a later age, so that many more men remain celibate at 40 years than formerly. This, of course, cannot be taken as a single and isolated fact. It is associated with the greater strain and tension required to make a position in life, and is also associated with the growth of ideas of luxury which are present now both with men and women. But a still more serious fact is that after these marriages there are fewer children and also that mothers much less frequently see their offspring than they did. There, again, they look up the facts of pregnancy and lactation as interfering with their busy social life, therefore they avoid these contingencies as much as possible. I believe sexual continence is possible and admirable, but it is constantly nowadays replaced by onanism, and though I do not attribute any serious increase of insanity to this head, yet the dread of its results, which is so commonly enforced upon the public by quacks, has a very serious influence in producing a number of youthful hypochondriacs and a considerable number of suicides. A few days pass but that I am consulted about the effects of onanism in the production of insanity. I do not believe that it produces more insanity than it did formerly, except that there are more celibates who indulge in the habit to a longer period and greater extent than if they married early. I am also frequently consulted about women whose whole mental character has become changed as a result of restriction in child-bearing and nursing. On some, probably the majority of civilised women in England and France nowadays, the feeling that in thus acting they are opposing Nature's law does not weigh very heavily. But still, there are many women who feel degraded, and even sinful, in thus acting and I know that many leaders among obstetric physicians recognise the neurotic woman who is produced by conjugal frauds. Though I should not say that this class adds very materially to the sum of the increase of insanity, yet I must speak very definitely as to my belief that it contributes to a certain amount.

And now to proceed to the definite conclusion of the whole matter. I have already said that, in my opinion, there is an increase of insanity, that this has been steady in all classes of society, and that the reports of the Commissioners of England, Scotland, and Ireland all support this statement. So far as the lower orders are concerned the statistics are clear, but as regards the upper classes the different countries there seems to be a decrease. To this I shall refer later. There has also been a slight temporary decrease in Scotland and England, but this really does not, I think, interfere with the pretty steady tide of increase. In England there is this year a decrease among registered or certified patients of unsound mind. But, as I have said, this is of very little value, I think. For, especially in reference to the richer classes, whatever may be said as to the feeling among the poor in relationship to asylums and certification, I believe there never was a time when the word "asylum" and the term "lunatic" were more dreaded among the well-to-do than at present. Among the causes for this increased dread doubtless is the growth by education of the feeling of the danger of inheriting mental disorder. If I have been able in any way to show that this dread is too dominant good may result. The feeling undoubtedly exists that insanity is one of the most transmissible of all diseases, and this has weighed, and still weighs, heavily on the lay mind. They will ignore other forms of disorder, even though they may be somewhat serious, but they will not admit the existence of insanity in the family unless it is absolutely forced upon them. Anything that can be treated in a home of rest by Dr. Mitchell, or by change of residence and travel, appears as

thing to their minds, but as soon as a patient has been certified they believe an indelible blot rests on the family, a blot which will have a serious influence upon the future, say, marriageable daughters. When I tell you that there are several thousand medical men in England who are willing to certify so-called mild mental cases into their homes it really shows how widespread this home-treatment of nervous and mental diseases is. Therefore, when the Commissioners report a decrease in the certified insane in England, it of course has to be discounted very seriously by the fact that the dread of asylums and the fear of certification act so strongly that many patients who had better be certified are sent into private care. The various bodies of commissioners have felt it their duty to consider especially the question of the increase of insanity, and so far as possible to reassure the public that they, at all events, have no great fear of any serious increase.

And now I must proceed to details; and although I cannot expect to make the dry bones of statistics live, yet I will make such use of them as is necessary. On January, 1906, there were 121,976 certified patients in England, this being an increase of 2150 on the year 1905. This rate of increase is less than that of the average increase of the previous five years, which was an average yearly increase of 2807, the average increase for the ten previous years being 2554. The chief decrease was in the numbers of private patients in licensed houses. It is important, as I shall have to repeat later when considering the apparent increase of the poor in asylums, to recognise that many more patients are now sent to asylums who formerly were retained in workhouses. Thus, nearly 50 years ago only 58.2 per cent. of the pauper lunatics were in asylums. This is a very important fact to remember, for recently in England, Scotland, and Ireland pauper persons of unsound mind of all degrees have been swept into the class of certified lunatics, and this class in future will not be so efficient in adding to the numbers of the certified insane. The greatest increase is noticed in England in the metropolitan area and in the home counties. The lodestone of the capital attracts the weak even more than it does the strong, the failing in mind and morals become aggregated in the larger centres in increasing numbers. If we compare the returns of the certified insane in 1859 with those of 1906 the numbers are startling if not appalling. In the former year in England and Wales there were 38,782. Now there are 121,976, that is an increase of 231 per cent., while the population increased during that period only 75.4 per cent. The ratio of certified patients to the general population in 1859 is 1 to 283, that is, 35.31 to every 10,000 inhabitants, whereas in 1859 it was only 18.64 per 10,000. In passing, I may refer to the recovery rate, which I regret to say does not in any way encourage one to think that the present humane methods of treatment have greatly increased the numbers cured. In an article "Statistics of Insanity," by Sir Charles Hood from 1846 to 1855, he refers to the percentage of cures being quite as high as at the present time. He gives the aggregate of the 100 years ending Dec. 31st, 1855: admitted into Bethlem Hospital, 19,373 patients; cured, 8341, a percentage of 43.5. From 1846 to 1855, 2726 were admitted, and during that period the high percentage of recoveries was 54.19. It is well, of course, to remember that the patients admitted into Bethlem Hospital were and are of a special type, no chronic, or incurable, or epileptic cases being received. But even taking that into consideration the rate of cure of the last return is no higher than it was nearly 100 years ago and no higher certainly than it was 50 years ago. This all points, I think, to the fact that only a certain number of insane are curable under any conditions whatever, and that the idea of any universal system of treatment greatly increasing the recovery rate is altogether misleading. The Scotch Commissioners this year give an account of the increase since 1853, in which year there were 5824 certified patients, whereas on Jan. 1st, 1906, there were 17,450, showing an increase in nearly half a century of 11,626. This increase is confined to the general public asylums, there being a decrease of 624 in the residents in private asylums. A very large increase of patients in private dwellings is noted, and this is a point of special interest in Scotland, where the system of boarding-out is carried on largely and successfully and certainly more than is possible in England. In Scotland during the last three years there has been a decrease of insane persons in proportion to the population, and this is the first time such a thing has occurred since 1853. During the whole period the lunatics

have increased 200 per cent., while the population has increased only 56 per cent. Among the causes of total increase of admissions are a large number of senile cases from infirmaries, but this must not be taken to connote a general deterioration of the race. In Scotland, as elsewhere, the struggle for existence renders it more difficult for the poor and healthy to maintain the feeble or insane in their own houses, the residence of such people interfering with the wage-earning capacity of the family, so that it is altogether easier for them to contribute something towards the maintenance of a patient in an asylum than to keep him at home. And with the steady development of treatment of weak-minded and feeble people in cottage homes the demand has created a supply that proves, at all events in the north, to be quite satisfactory. It is noteworthy that—whether there is an increase in other forms of mental disorder or not being doubtful—there is in Scotland as well as in England a marked increase in the number of general paralytics. Not a quarter of a century ago the numbers were quite small; now they are large and increasing. And what is more astonishing is that the increase is more marked and more recognised in Edinburgh than in Glasgow, though, as a rule, one finds more general paralytics in big manufacturing cities than in smaller residential capitals. Another anomalous point among the general paralytics of Scotland is that the increase has been more marked among women than among men. The increase of general paralytics, then, is one of the distinct causes of increase of insane individuals. The Irish Commissioners this year have made a special report on the alleged increase of insanity. I have already had occasion to quote from this and it will be necessary now to refer to it more in detail. The contribution has the advantage of giving the individual opinions of the superintendents of the various asylums and also the conclusions arrived at by the Commissioners themselves. I may briefly, before referring to the detailed reports of the Commissioners, give their conclusions, which were: That the apparent increase is due chiefly to accumulation and that the increase is more apparent than real; that patients live longer, being retained longer in many cases (in many cases all their lives) in asylums. In reference to this I might quote Dr. William Farr, who thus expressed the same idea: "There may be ten times as many lunatics in civilised as in barbarous countries, and not because the tendency of insanity is greater but because the lunatics live ten times as long as they did." The increase depends, too, on the withdrawal of a large number of quiet, harmless, senile, or weak-minded persons from their homes. This is shown by the fact that the general census returns showed the number of such persons to be very greatly reduced. Doubtless the drawing of the healthy and able-bodied to the cities and to the colonies has also tended to the removal of the more feeble to the asylums, as there were fewer people personally able to look after them. The unusual increase pointed to some special causes and the Commissioners have given their report under five headings. To some of these I have already referred: heredity, including consanguineous marriages, malnutrition and bad diet, the inordinate use of stimulants, and mental strain due to agricultural depression. These returns provide very interesting matter for further consideration. The effect of emigration has been that the healthier and younger go abroad and the less fit and the older remain behind; and, what is certain, quite a considerable number of those who break down in America are repatriated as insane, so that the healthy remain there, whereas many of the feeble are returned to swell the list of lunatics in Ireland. This is made clear by the fact that in the 30 years between 1871 and 1901 there was no increase in the proportion of insane in reference to population between the ages of 20 and 55. There was, however, a very large increase in the ratio of insane to population in the old-age period. In Ireland the amount of insanity in proportion to the population is greater in the most remote rural districts, whilst in the busiest towns the ratio of the insane to the same population is lowest. This is due, of course, to the exodus of the healthy from the country places. Even the first admissions are misleading, as these represent failures after residence at home; so that a very large proportion of people who come under the head of "first admissions" after all have been insane for long periods before they are sent to an asylum. It has often been said that the only way we can judge of the relative increase of the insane in a country is by reckoning the number of first admissions; and the Commissioners in Lunacy have, of recent years, taken special pains to show the proportion of

first admissions to other admissions. It is an interesting point, and one not easy to explain, that the Irish in America produce a much larger proportion of insane patients than any of the other emigrants. I remember being very much struck myself when in America with the very large numbers of physical, social, and mental failures represented in the asylums and infirmaries near New York that the Irish provided. This has, of course, been explained by the instability of the Celtic temperament, but that hardly seems sufficient. Doubtless there are other contributing causes; among others, the home-loving instinct of the Irish is very characteristic and also their tendency to wander. And this tendency to wander is pretty frequently recognised as an early symptom of mental disorder. It might be interesting to note that similar conditions exist in America.

Before proceeding to my general summary and conclusions I feel that I cannot do better than quote from Dr. Mott:—

A pathology which only considers the morbid macroscopic and microscopic anatomy is useless; there must be a correlation of the clinical and psychological symptoms with the morbid physical, chemical, and structural changes of the organs and tissues of the body, particularly of the brain. No one who has had any practical experience of insanity can come to any other conclusion than that the majority of people become insane because there is an inborn tendency in their nature. In fact, the pathology of the causation of insanity of an individual resolves itself into a study of his personality—what he was born with and what happened to him after birth. Numbers of factors may conspire or combine after birth to bring out this innate tendency to mental derangement. It may be asked, Can a stock which is sound mentally become unsound by its members being subjected to an unfavourable environment? Many people deny the possibility of mutation in the germ plasma, but as the nervous system is the latest and most complex and differentiated tissue in structure and function mutations and variations may occur in consequence of favourable or unfavourable environment. The commingling of the germ cells of two stocks of suitable or unsuitable temperaments may by a happy or unfortunate chance produce sporadic genius or sporadic insanity.

And now to proceed to my general conclusions. I do not find there is any real ground for alarm in the increased number among the insane. There are many reasons for the apparent increase, as I have already pointed out. I do find there is an increase of insane persons suffering from general paralysis of the insane and from the various forms of senile dementia; but I do not think there is any evidence pointing to alcoholic excess as at present causing any real increase. I think influenza, on the other hand, has had a very serious effect in predisposing to nervous instability, which predisposes to neurosis generally, and to insanity undoubtedly. And thus, though general paralysis and influenzal infection may be causes of insanity, I cannot believe that any real benefit will follow any definite medical treatment of insanity as one disease. That the time is approaching when general paralysis may be found to be a curable disease is possible, and that we may learn a great deal from the clinical study of the forms of insanity depending upon micro-organisms I also admit, and that it will be a great advantage to the world at large, and to the medical profession in particular, when there is greater convenience for the study and investigation of mental disorders. It is, however, extremely difficult to understand how the huge mass of chronic insanity is ever to be dealt with. England is becoming more and more crowded and therefore is less able to have detached colonies where the weak-minded of all classes and both sexes can be segregated. That very great good may result from the early treatment of the insane is shown by the experience of Dr. J. Carswell at the Glasgow Hospital for the Insane. They have two wards specially adapted for the reception of acute cases of mental disorder, and it is remarkable that a very large proportion of these are cured or recover and are allowed to go home without having to be sent to an asylum. Altogether, of 1027 admissions into the hospital 583 had to be sent to asylums, 415 were discharged well, and 30 remained under treatment. Of those certified 164 had had previous attacks and only 364 represent acute fresh cases. The number represents the annual production of pauper lunacy. The proportion per 10,000 of population for the year was 5·87—that is, less than 6 per 10,000 of the population became pauper lunatics in 1905-06. When viewed in the mass the statistics of pauper lunacy look alarming, but such a proportion occurring in a large industrial population such as that of Glasgow is not a real cause of fear. It is noteworthy, too, that there is no increase in persons of the young and the middle ages, the increase being greater after the age of 60. There has been no increase of late years in Scotland and Dr. Carswell is hopeful that the high-water mark has been reached.

So far, then, I have brought my subject to a close, and there is an increase among the insane, that it is not alarming,

either in number or in quality, that many other causes besides inheritance contribute to these mental catastrophes. And one feels that there is still scope for treatment of many cases of mental disorder perhaps on different lines from the past. But with all hope one must mingle caution.

The Hunterian Lectures

OR

THE PATHOLOGY OF MELANOTIC GROWTHS IN RELATION TO THEIR OPERATIVE TREATMENT.

*Delivered before the Royal College of Surgeons of England on
Feb. 25th and 27th, 1907,*

By W. SAMPSON HANDLEY, M.S. LOND.,
F.R.C.S. ENG.,

HUNTERIAN PROFESSOR; ASSISTANT SURGEON TO THE
MIDDLESEX HOSPITAL.

LECTURE II.¹

Delivered on Feb. 27th.

MR. PRESIDENT AND GENTLEMEN,—My last lecture was mainly occupied with a study of the course of dissemination in a case of melanotic sarcoma which, pending wider investigations, must be taken as typical. I endeavoured to show that centrifugal permeation of the lymph-vessels round any focus of melanotic sarcoma, whether primary or secondary, is the primary factor in dissemination, and that embolic spread by way of the blood stream is a later event, dependent on the infiltration and invasion of the veins and arteries from comitant permeated lymphatics. In the present lecture I propose to consider briefly and in somewhat disconnected fashion some miscellaneous points connected with the pathology of melanotic growths, reserving the most important question, that of operative treatment, for the latter half of my lecture.

Some writers have used the term melanoma as equivalent to "melanotic sarcoma." Although this usage has the authority of Mr. F. S. Eve,² it is, I think, better to use the word "melanoma" for all tumours containing melanin granules, whether simple or malignant. Just as a distinction is drawn between a simple and a malignant adenoma, so the melanomata may be divided into simple and malignant melanomata. It is probable that the melanomata only occur in situations where melanin-containing cells are normally found. These tumours occur most commonly upon the skin, especially upon its deeply pigmented areas, and within the eye. More rarely they may arise upon those mucous membranes which march with the skin at the orifices of the mouth, the anus, and the vagina. As rare curiosities they have been met with in ovarian dermoids and in one unique case a melanotic tumour arose in the spinal cord.³ They occur in horses, most commonly in grey horses, in oxen, and in dogs, as well as in the human race. It is relevant to note that Mr. H. W. Acton has observed pigmented cells in the skin of ovarian dermoids and that pigmentation of the spinal pia mater is commonly met with. In view of these facts it is necessary to consider what light normal histology can throw upon the origin of the melanomata.

THE CHROMATOPHORES.

Connective tissue cells containing melanin granules, stellate in shape, with many long branching processes, or fusiform with long pennant-like terminations, occur in the upper layers of the dermis, more especially in areas of normally pigmented skin, such, for instance, as the skin of the scrotum and of the mammary areola. These cells resemble in every respect the pigment cells of the choroid. They are found more abundantly in the skin of the negro than in that of the white man, and the darker the tint of the skin the more numerous are the chromatophores of the underlying dermis. Nevertheless, the bulk of the pigment in the negro's skin does not lie in the dermis but is collected in the deepest or protoplasmic layer of the

¹ Lecture I. was published in THE LANCET of April 6th, 1907, p. 927.

epidermis. It would thus appear at first sight that epithelial cells, as well as connective tissue cells, possess the power of elaborating melanin, and presumably also of originating melanotic tumours. Repeated observations have, however, convinced me that the pigment granules of the stratum mucosum of the negro's skin form a branching network which is mainly intercellular in position. Occasionally the main lines of this network can be seen passing down into the underlying dermis. These observations support the view which holds that the pigment of the negro's epidermis is not produced within the epithelial cells but is contained within long branching processes of the underlying connective cells or chromatophores, which thrust themselves between the adjoining epithelial cells. You will remember that the pigment cells of the reptilia possess great amoeboid power, sometimes thrusting out long pigmented processes and again withdrawing them if the light becomes intense. In the negro's skin a rete of similar pigmented processes derived from the dermis appears to enwrap the deeper epithelial cells of the epidermis, much as the dendron of a nerve embraces a nerve cell. I notice that Mr. Willmott H. Evans in his recent Erasmus Wilson lecture on Leucoderma¹ has expressed views very similar to those just stated. If the melanin granules of the negro's skin originated within the epithelial cells it would be natural to expect that the older horny cells would still contain the inert and stable melanin particles originally formed in them. This is not the case; the superficial layers of the negro's epithelium are almost entirely free from melanin granules. It would appear that the growing epithelial cells as they are pushed towards the surface extricate themselves from the entangling network of processes and show themselves in their true character as unpigmented epithelial cells of the usual type.

Mr. Willmott Evans, in the valuable lecture to which I have referred, quotes Karg's experiments on skin-grafting from a white man to a negro and *vice versa*. Negroid skin soon loses its pigment when transferred to a white man, while the skin of a white man becomes dark when implanted upon a negro. Since the epithelium is the vital element of a skin graft it seems a fair inference that the dermis, and not the epithelium, is the vital laboratory for pigment and that the epithelial layer is only passively impregnated by the pigment produced deeper down in the chromatophores of the dermis.

THE RELATION OF CHROMATOPHORES TO HAIR.

Attention does not seem to have been called to the special abundance of the chromatophores in the vascular mesoblastic papilla upon which the bulb of a human hair rests, and in the growing mass of cells which forms the hair bulb itself. The fact is not without significance in view of the abnormal formation of hair which is so often seen in moles. It would appear that the chromatophores play an important part in the nutrition of the hair, even if they do not enter into its structure. A study of the structure of the hair papilla appears to throw light upon the polymorphism of the cells of malignant melanomata. In some hairs, presumably young ones, the hair papilla consists entirely of richly protoplasmic round or fusiform cells, quite devoid of pigment, and hardly distinguishable from the cells of the hair bulb. In others, again, unpigmented fusiform cells are mixed with fusiform pigmented cells—typical chromatophores (Fig. 10). The long processes of these chromatophores, and even the cells themselves, often pass in between the overlying cells of the hair bulb, so that an appearance is produced like that of the negro's epidermis. Sometimes coarse pigment masses are seen between the chromatophores, and these are presumably cells which have become so pigmented that their cellular identity is lost. Other hair papillae are fibrous in structure, with scanty nuclei and little or no formation of pigment. There can, I think, be no doubt that the various forms of cell found in the hair papilla, varying from a richly protoplasmic rounded cell to a typical branched chromatophore, are stages in the development of one particular form of cell, and that the pigment-masses or fibrous bundles are stages in the degeneration of the same variety of cell. Action has observed collections of chromatophores at the base of the hooklets which stud the shark's skin. Here, again, the chromatophores are seen playing a part in the nutrition of the epidermis. A consideration of normal minute anatomy thus points to the view that the malignant melanomata are mesoblastic and not epithelial tumours, and supports

Ribbert's view that the malignant melanomata are "chromatophoromata," and that the varying forms of cells found in them all represent stages in the development or decay of the normal chromatophore.

Passing now from the normal melanin-forming cells of the body we must briefly consider the simple or non-malignant melanomata.

PIGMENTED WARTS AND MOLES.

In English surgical literature, as Dr. Wilfrid Fox has pointed out, the name *nevus* is often restricted to an area of skin which exhibits an excessive formation of blood or lymphatic vessels, while by the Germans the name *nevus* is applied to any localised patch of skin which shows defective development and a fibro-cellular structure, quite apart from the question of its degree of vascularity. Thus, all the abnormally pigmented patches of congenital origin which are so frequently present upon the skin are included by the Germans under the heading of "pigmented *navi*." They may appear as simple black or brown stains—beauty spots—or as raised patches of varying size and shape, often covered with hair, or as pigmented warty areas with evident papillary prominences—the "wart-fields" described by Mr. J. Bland-Sutton. Dr. Max Tische² has recently investigated the little bluish spots, "blue *navi*," coloured like gunpowder tattooing, which are frequently seen.

All these varied forms of simple melanoma are practically identical in structure. They show pigmentation either of the stratum mucosum of the epidermis, particularly in the inter-papillary-epithelial cell columns, or of the sub-epidermal layer of the corium, or pigmentation of both layers. Apart from their pigmentation the simple melanomata are characterised by the presence of lines and groups of unpigmented richly protoplasmic cells, "*nevus* cells," fusiform or rounded in section, lying in the superficial third of the thickness of the dermis, but deep to its pigmented layer. (Fig. 11.) Save that the *nevus* cell is smaller, the appearance presented by these simple melanomata is frequently indistinguishable over considerable areas of the section from the microscopic appearance of an alveolar melanotic sarcoma. (Fig. 12.)

The warty overgrowth seen in certain moles would appear to be a secondary characteristic, probably dependent upon a local imperfection of the lymphatic circulation. Warty overgrowth as a consequence of lymphatic obstruction is familiar in elephantiasis.

THE NATURE OF NEVUS CELLS.

Malignant melanomata of the skin appear, as a rule, to be derived from the *nevus* cells of pigmented warts and moles. If these cells are shown to be of mesoblastic origin, then the malignant melanomata are sarcomata. If, on the other hand, they are epiblastic in origin, then the malignant melanomata are carcinomata.

According to Borst and Bajer the lines and groups of *nevus* cells are derived from the inward proliferation of the endothelium of the lymphatic vessels and spaces. Borst points out that pigmented cells occur only in the superficial layer of the corium, between the *nevus* cells and the epidermis, and further that in this layer evidence of cell proliferation is absent. Ribbert has observed transitional forms between the unpigmented spindle-shaped *nevus* cell and the typical pigmented star-shaped chromatophore. He holds, upon arguments which seem to me convincing, if not conclusive, that the *nevus* cells are young chromatophores which have not yet acquired their pigment. Since the chromatophores are branched connective-tissue cells lying within, or lining the walls of, lymphatic spaces there is no contradiction between Ribbert's view and that of Borst. In sharp contradistinction to these views is the opinion of Unna and his school in Germany and of Mr. Eve, Dr. Wilfrid Fox,³ and others in this country. Unna believes that the lines and groups of *nevus* cells are derived from down-growing processes of the cutaneous epithelium. In my opinion, although I approached the subject expecting to be convinced of the carcinomatous nature of malignant melanomata, the views of Unna are certainly erroneous. Frequently, in pigmented moles, the epidermal layer is practically normal and is everywhere separated from the underlying *nevus* cells by a thin perfectly continuous layer of fibrous tissue. Moreover, though I have seen *nevus* cells

¹ M. Tische: Ueber Benigne Melanome, Virchow's Archiv, Band cxxviii, p. 232. I am indebted to Dr. Tische for kindly sending me some of his specimens.

Wilfrid Fox: British Journal of Dermatology, January, 1906.

coming into very close relation with the overlying epithelium, and indeed apparently continuous with its down-growing processes, it is always possible to say within narrow limits where the epithelium leaves off and the *navus* cells begin. The tendency of the normal *chromatophores* to thrust their processes between the deeper layers of the epithelium sufficiently accounts for the absence of a sharp line of demarcation. The richly protoplasmic nature of the *navus* cells may indeed give them an appearance like that of an epithelium, but such an appearance is valueless as a proof of their epithelial nature. Connective-tissue cells may closely simulate an epithelium. For instance, the layer of odontoblasts in a developing tooth, although admittedly of mesoblastic origin, may present all the appearance of a layer of epithelium. In shape, size, and other respects the *navus* cells in many moles are entirely unlike cutaneous epithelium. It is only exceptionally that the appearance of the two kinds of cell is so similar as to lead to confusion. Lastly, the intercellular prickles of cutaneous epithelium have never been demonstrated between *navus* cells. Blood-vessels may be seen running within the groups of *navus* cells.

The intimate relations which I have observed between the *chromatophores* of the hair papilla and the bulb of a normal hair may serve to explain many of the peculiarities of pigmented moles. A mole may be regarded as a district in which the down-growing processes of epithelium from which hairs are derived have failed to come into proper apposition with the upgrowing dermal hair papilla. The mesoblastic cells (*chromatophores*) of the abortive hair papilla proliferate abnormally and form *navus* cells, while the down-growing epithelial processes remain to convey the erroneous suggestion that *they* are the source of the groups of *navus* cells with which they are sometimes apparently welded. Thus a pigmented mole might, perhaps, not inappropriately be described as a trichoma, a hair tumour, originating not from the down-growing epithelial process which forms the hair but from the up-growing mesoblastic hair papilla. Such a view provides a plausible explanation for the down-growing epithelial cell columns so often seen in moles and for their intimate connexion with the *navus* cells derived from the abortive hair papillæ.

THE ORIGIN OF MALIGNANT MELANOMATA FROM SIMPLE MELANOMATA.

In a large majority of cases malignant melanoma arises in connexion with a pre-existing simple melanoma. Mr. Eve, to whose well-known work on the subject I am much indebted, states that 26 out of 33 malignant melanomata of the skin occurring at the London Hospital arose in pigmented moles. The onset of malignancy is usually indicated by the enlargement of the mole, but, as Mr. Eve points out, the primary growth seldom exceeds a walnut in size. Occasionally, as in melanoma of the vulva, or in Mr. Jocelyn Swan's case of melanoma of the face, which his courtesy enables me to show you, the primary growth may attain a large size. Frequently there is hæmorrhage and sometimes a discharge which may be offensive. Occasionally no apparent change occurs in the mole and its malignancy is signalled only by the appearance of metastases (Eve). Sometimes no primary growth can be found. Dr. G. Newton Pitt informs me of a case upon which a necropsy was made by Dr. Hilton Fagge. All the organs had been removed and no primary growth could be detected anywhere. Dr. Fagge examined the lowest inch of the rectum, which had not been removed, and found the primary melanotic growth there.

THE ORIGIN OF MALIGNANT MELANOMATA APART FROM PRE-EXISTING SIMPLE MELANOMATA.

Mr. Eve has drawn attention to the malignant melanomata which arise in the scar of a punctured wound. He records two cases:—

A lady, aged 65, had a melanotic growth over the head of the fourth metatarsal bone from which she ultimately died. 20 years previously she wounded her foot upon the seashore. A slight thickening of the skin remained, and three months before she came under observation the thickened part began to enlarge until a definite tumour formed.

A lady, aged 39, stated that ten years before she came under observation she ran a splinter of wood under the skin of the right thumb. Blood accumulated under the skin and subsequently a black spot remained. This pigmented spot gradually spread and ultimately it ulcerated and gave rise to secondary growths in the epitrochlear and axillary glands.

Mr. Bland-Sutton has drawn attention to the implantation cysts, lined by epithelium, which originate from particles of integument carried down into the subcutaneous tissues by an injury. I would suggest that the melanomata which

originate in the scar of a puncture are due to the traumatic implantation into the subcutaneous tissues of a group of dermal connective-tissue cells,—of actual or potential *chromatophores*.

Another interesting group of skin melanomata are the whitlows. The term is, perhaps, unfortunate as it suggests that the tendon sheaths are implicated, which is not the case. The disease appears to begin as an ordinary chronic inflammation of the paronychia skin or of the pulp of the finger. Its real nature is often only indicated by a narrow black line in the skin forming a border to swelling. In other cases (Ledlard, Barnard) no period of apparent inflammation precedes the definitely recognisable tumour. Mr. H. L. Barnard, who has studied these tumours, tells me that they commence in the paronychia skin and in the matrix of the nail, which is only secondarily affected. They occur most frequently upon the outer side of the great toe and upon the index finger. In the latter situation they have only been recorded in female patients. Cases have also occurred upon the thumb and upon the fifth finger.

It appears to me that these growths, too, are implantation melanomata. The cases which appear at first inflammatory may be due to the simultaneous inoculation of bacteria and of pigmented connective-tissue cells. When they occur upon the hand the site of the growth and the sex of the patient point to needle-pricks as the injury concerned. Mr. Barnard informs me that his patient was much occupied in sewing. In the recorded cases it is not stated which hand was affected; presumably the left hand would be more liable to such injuries. The historic connexion of the London Hospital with the melanomata may depend on the tailoring and sewing industries of the surrounding district, just as that of Guy's Hospital with anthrax depends on the tanning industry of Bermondsey. In the case of the great toe the sharp edge of an ingrowing toe-nail would appear to be the weapon concerned. This is indicated by the preference of melanotic growths for the outer side of the great toe. These growths, too, must be looked upon as implantation melanomata. Sir Frederick Treves has recorded a melanoma of the palate due to the pressure of a denture, and melanotic growths have repeatedly been recorded as commencing in the lower part of the rectum, a part very liable to punctured injuries by fish bones. The malignant melanomata of the skin may thus, I believe, be classified in two groups: (a) those originating from simple melanomata and (b) implantation melanomata arising from the traumatic implantation of *chromatophores*.

The following case, recorded by Norris, is of interest in connexion with this question of implantation.—

The patient was a woman, aged 26 years. Three years previously her brother ran a pair of scissors through a mole between her shoulder, and a dark brown coloured stain, the size of a large nut, afterwards surrounded the mole. 12 weeks ago the mole began to increase and grew to the size of a moderate mushroom. It was oval, black, soft, elastic, and pedunculated. There was also a small tumour like a black grape near its upper surface. Mr. Norris removed the disease with abundance of the surrounding substance and predicted recurrence, but none occurred in eight years.

THE MICROSCOPIC STRUCTURE OF MALIGNANT MELANOMATA.

Borst describes three varieties of structure in primary malignant melanomata: (a) Those consisting of slender spindle cells, the ends of which are continued into very long branching processes. Stellate, round, and oval cells are often also present. In this variety of growth the cells are easily to be recognised as *chromatophores*. (b) Those consisting of spindle-shaped cells arranged in intercrossing

bundles. In section these growths present an alveolar appearance, the alveoli containing apparent round cells which are really spindle cells in cross section (Ribbert). (c) Those consisting of large cells, round, oval, or polygonal in shape, arranged in alveoli separated by strands of connective tissue. This is the variety which closely resembles a carcinoma.

Besides these varieties I am able to show you a peculiar form of malignant melanoma, apparently due to sarcomatous degeneration of the perivascular connective-tissue cells of a cavernous naevus (Fig. 13). The overlying cutaneous epithelium is normal. You will notice that in the fully developed pigmented portion of this tumour (Fig. 14) the blood-vessels constitute the only stroma which is present and that each vessel is thickly clad with many layers of tumour cells, which are more loosely scattered in the inter-vascular spaces. It is obvious that a tumour with these characters, resembling in structure a perithelioma, could never be classified as a carcinoma.

The distribution of pigment in malignant melanomata is very irregular. Sharply defined portions and even the whole of the primary growth may be free, or nearly free, from pigment. As regards the secondary nodules some may be coal-black, while others in the same organ are colourless. The glandular metastases generally show deep pigmentation.

MELANIN.

Much disagreement has existed as to the nature and origin of melanin. Some authors maintain that it contains iron and is derived from the pigment of the blood, others maintain that it is free from iron and deny its origin from the blood. M. B. Schmidt⁷ has shown experimentally that iron-free pigments may be derived from blood pigment, and, further, that in melanotic tumours some of the melanin granules may give the micro-chemical reactions for iron, while other melanin granules in the same specimen remain unstained. He concludes that melanin is derived from the blood and that consequently in the early stages of its formation it contains iron, which, however, it has lost by the time its chemical development is complete. In fact, the term "melanin" is a histological one, not a chemical one, and is applicable to pigment granules some of which may contain iron; but in what may be regarded as its typical form melanin is iron-free. The remaining chemical characters of melanin are well known and need not detain us. It is, however, of practical importance to note that melanin is bleached by chlorine, a fact which enables it to be distinguished from the carbon particles so frequently present in lymphatic glands.

Ribbert,⁸ in a paper which, to my mind, almost conclusively proves that the malignant melanomata must be classified among or near the sarcomata, has brought forward some new facts, chiefly derived from the examination of fresh teased-out preparations. According to Ribbert's observations the cells of melanotic sarcoma of the eye agree with the normal pigment cells of the choroid in all particulars, showing in fresh teased-out preparations star-shaped cells with long multiple processes, or spindle cells with their ends prolonged in similar and often very long processes. (Fig. 15.) Some of the cells are entirely filled, except in the nucleus, with pigment granules; in some the granules are universally but more sparingly distributed, others are entirely free from pigment. The granules are principally found in the peripheral layer of the protoplasm, and this applies both to the cell body and to its prolongations. Among the branched elements, round or oval, intensely pigmented cells without processes are to be seen. In the older parts of the tumour star-like pigment cells are wanting and spindle cells with long prolongations may be seen lying parallel in bundles. Frequently dichotomous branching of the processes can be made out. Evidently these are not ordinary spindle cells such as are found in spindle-celled sarcoma, although in sections, when shorn of their processes, they may present an identical appearance. But besides these peculiar spindle cells there may be found round, oval, spindle-shaped, or stellar elements devoid of processes containing dense aggregations of large pigment granules, or large pigment masses may be seen obscuring the cell structure and often apparently replacing it. Transition forms may be observed between the cells with processes and those devoid of processes. These serve to show that the two varieties of cells represent different stages of a single-cell variety, or

perhaps different degrees of contraction of the cell protoplasm such as is seen in the pigment cells of reptiles.

The preceding observations apply only to tumours in an early stage of development. In later stages the branching character of the cells is lost, and they resemble those of an alveolar sarcoma, appearing fusiform or round, according as the cell is cut longitudinally or crosswise.

In the metastases of melanotic sarcoma of the choroid, as well as in the primary growth, all these forms of cells from the typical star-shaped chromatophore with long processes to the round pigment mass occur. From all these facts Ribbert concludes that the characteristic elements of melanotic sarcoma of the eye are the chromatophores, which, however, in the course of their growth may suffer many modifications or may remain undeveloped and free from pigment, resembling in this latter respect the normal chromatophores when they first appear in the developing embryo.

Similarly Ribbert regards melanotic sarcoma of the skin as a tumour arising from the chromatophores of the cutis. He believes that the naevus cells are young chromatophores, holding the same relation to the developed pigmented cell as the unpigmented cells of a melanotic sarcoma hold to the pigmented ones. One of the commonest melanotic sarcomata is characterised by the presence of pigmented cells exclusively in the inter-alveolar tissues, while the alveolar groups of cells are free from pigment. In certain warts, on the other hand, all the alveolar cells are pigmented. Evidently the non-pigmented cells have a latent capacity for developing pigment. Moreover, in teased preparations the alveolar non-pigmented naevus cells are frequently seen as angular cells with short processes. Transitional forms between the naevus cell and the stellate chromatophore can be traced, and in places typical chromatophores pass into typical naevus cells without any sharp boundary. It is to be noted that complete development of the chromatophores as regards their processes and their pigment is only seen where they lie near the epithelium. Thus Ribbert finds that in respect to varying degrees of development of the same kind of cell, the identical appearances found in pigmented warts also occur in melanotic sarcoma, save that in sarcoma the cells are larger than in simple warts. He concludes that melanotic sarcoma of the skin, like that of the choroid, is a "chromatophoroma," a view which he confirmed by detecting typical stellate chromatophores in teased specimens of melanotic sarcoma; for instance, in a metastasis from a melanotic sarcoma of the pinna, in melanotic sarcoma of the labium minus, and in a melanotic sarcoma in a dog. A melanotic sarcoma of the great toe consisted exclusively of typical branching chromatophores (Fig. 15), but this is an exceptional event. As a rule the origin of the cells of a melanotic sarcoma from chromatophores is obscured by the loss of their processes and by the excessive deposition of pigment within them.

AT WHAT STAGE OF THE DISEASE DOES BLOOD DISSEMINATION COMMENCE?

We have obtained strong microscopic evidence that the process of dissemination in malignant melanoma is primarily one of centrifugal lymphatic permeation. There is almost equally strong evidence from the results of necropsies that in the later stages of dissemination the blood-vessels are the channels, and the blood itself the vehicle and motive power of detached emboli which form secondary deposits. The crucial point to settle as determining the prospects of surgical interference in malignant melanoma is this: At what period is lymphatic dissemination supplemented by blood dissemination? When once viable fragments of the growth are launched into the blood stream the surgeon's hand is paralysed and the patient must depend entirely on the natural forces, always inadequate and frequently altogether absent, which tend to the destruction of the embolised fragments.

Fortunately it would appear that as a general rule blood invasion does not take place at an early stage. This is indicated, *primâ facie*, by the comparatively long average duration of the disease, which has been estimated at three years. If malignant cells obtain access to the blood in the early stage of the disease, the natural powers of resistance must inhibit their further development or surely the patient would succumb within a few months. In the second place, cases occur of death from intercurrent disease, in which lymphatic dissemination, sufficiently widespread to be inoperable, is seen unaccompanied by evidence of blood dissemination. And, lastly, most extensive lymphatic

⁷ Virchow's Archiv, Band cxx. and Band cxxiii.

⁸ Ribbert: Ueber das Melanosarkom, Ziegler's Beitrage, 1897, p. 471.

distribution of the disease may take place in the glands, the subcutaneous tissues, and upon the serous membranes without any of the nodular visceral metastases which are the usual result of blood embolism. The points to which I have referred receive illustration in the following cases.

A young woman who came under the care of Mr. Heath⁹ had a discoloured area of the size of a shilling on the back of her left forearm, apparently a *nævus*. An unsuccessful attempt to remove it by ligature had been made. Mr. Heath excised the piece of skin and also an underlying nœvoid-looking growth upon the fascia of the size of an almond. About six months later two small hard lumps appeared near her scar, with an enlarged gland in the axilla. The patient still looked the picture of health. The recurrent glands were removed but the patient died from pyæmia on the tenth day. In section the excised axillary gland was found to be perfectly black. It was as large as a tennis ball. At the autopsy several large masses of bronchial glands showing true melanotic pigmentation were found. In both lungs were numerous pyæmic deposits, besides which, however, the lower lobe of the right lung contained a soft melanotic deposit, while the left lung contained a similar mass near its root.

In this case, six months or more after the removal of the growth was deemed advisable, the only evidence of blood dissemination was the mass in the lower lobe of the right lung, and even this might with greater plausibility be ascribed to permeation round the infected glands at the root of the lung—the obvious cause of the invasion of the left lung at any rate. It seems highly probable that a free removal of the deep fascia round the growth would have prevented the local recurrence. This step would, however, have been useless without a simultaneous removal of the axillary glands. If at the first operation these glands had been removed it is likely that the extension of permeation to the supra-clavicular and thence to the bronchial glands would have been anticipated and prevented and that the patient would have been permanently cured.

In the following case¹⁰ very extensive lymphatic dissemination and invasion of the serous cavities had occurred with a minimum of evidence showing distribution of malignant emboli by the blood stream. A woman had noticed as long as she could remember a black wart situated three inches above the left wrist. At the age of 53 years the wart began to increase in size, without pain, but with occasional bleeding, and it was accordingly removed. It is interesting to note in connexion with Coley's work on sarcoma that an attack of erysipelas which supervened was without therapeutic benefit, for two weeks after the operation a small lump made its appearance in the scalp and before the patient left the hospital other smaller lumps appeared elsewhere. Increasing weakness and the appearance of new nodules were her only symptoms for about two years. At the end of this period, in November, 1868, she was admitted to the Middlesex Hospital under the care of Mr. T. W. Nunn. Over a hundred nodules were now present over the head, face, neck, trunk, and upper limbs, together with one below the left knee. Several of the larger nodules were ulcerated, bleeding freely at times, and exuding a clear yellow fluid. In this stage the nodules were painful. The patient died in January, 1869. The surface of her body was studded with innumerable nodules. "The smaller and more numerous of these are..... scattered over the trunk and neck; many are also on the arms and thighs and some few below the elbows and knees; a few also on the head and face." The glands in both axillæ were enormously enlarged, causing dropsy of the right arm. The left breast was shrunken and the right one was much enlarged and infiltrated by growth. The mesenteric, lumbar, pelvic, and anterior mediastinal glands were infiltrated, sometimes forming masses of the size of tennis balls. One such mass surrounded the vermiform appendix, and another occupied the space between the vagina and the rectum. A minute black point, of the size of a pin's head, was imbedded in the substance of the left kidney, but the viscera generally were free from disease.

The remarkable point about this case is the freedom of the viscera from invasion, except for the single minute renal deposit. It would appear almost certain that malignant cells must have obtained access to the blood stream. The inference is that in this exceptional case of malignant melanoma the resisting power of the blood was sufficient to

destroy the malignant emboli, an event which in breast cancer is the rule.

In the museum of Guy's Hospital there is a specimen which bears very directly upon this point. It is a kidney, itself entirely free from disease, so far as the naked eye can show, but imbedded in a mass of melanotic growth which is replacing the perinephric fat. It appears certain that, as frequently happens in breast cancer, the perinephric growth originated from malignant infection of the lumbar glands. If this is the case, it is evident that widespread lymphatic dissemination may occur in melanotic sarcoma without obvious evidence in the kidneys of embolic blood invasion.

THE OPERATION FOR MELANOTIC SARCOMA OF THE SKIN.

When malignant melanoma arises in the digits amputation should be performed at once. The operation should not be performed as if for a non-malignant condition. The flaps should never be cut so as to include any skin within, at least, an inch of the tumour. Moreover, they should be very thin, consisting only of skin and a very thin layer of subcutaneous fat, and not including the deep fascia. The flaps should be dissected up to a much greater extent than would be necessary merely to provide a covering for the stump. Over the whole of the area thus exposed the deeper subcutaneous fat and deep fascia should be dissected up towards the base of the finger or toe until the line of disarticulation or division of the bone is reached. The glands in the groin or the axilla are then to be removed.

When a melanotic growth occurs on the hand or the foot above the digits the question of amputation will always arise, but in early cases excision of the growth, even though it be attended by greater risk of recurrence, will usually be the operation of choice. If the glands are already palpably enlarged it is probable that anything short of amputation at the wrist or ankle is useless. When the growth starts higher up on the limbs, or on the head or trunk, amputation is replaced in most cases by excision. Museum specimens show how inadequate and empirical are the operations performed on these growths, even up to the present time. It is common to see the skin divided within a quarter of an inch of the edge of the growth. Invariably, so far as I know, the area of deep fascia removed is no larger than the area of skin excised, and consequently local recurrence in the neighbourhood of the scar is a very frequent event.

The principles upon which, in my opinion, the excision of a malignant melanoma should be carried out may be directly deduced from the drawing of dissemination round a focus of melanotic growth (Lecture I., Fig. 2). You will remember that it shows permeation spreading centrifugally in the lymphatic plexus of the deep fascia and invading skin and muscle secondarily over a smaller circular area. A circular incision should be made through the skin round the tumour at what is judged by present standards to be a safe and practicable distance. The incision, situated as a rule about an inch from the edge of the tumour, should be just deep enough to expose the subcutaneous fat. (See Fig. 16.) If necessary two radial linear incisions extending from the circular incision should be made on opposite sides of the tumour so as to facilitate the elevation of the skin flaps, which forms the next step. The skin, with a thin attached layer of subcutaneous fat, is now to be separated from the deeper structures for about two inches in all directions round the skin incision. At the extreme base of the elevated skin flaps a ring incision down to the muscles surrounds and isolates the area of deep fascia and overlying deeper subcutaneous fat to be removed. This fascial area is next to be dissected up centripetally from the muscles beneath up to a line which corresponds with that of the circular skin incision. Finally, the whole mass with the growth at its centre is removed by scooping out with a knife a circular area of the muscle immediately subjacent to the growth. The edges of the wound are to be brought together as convenience dictates.

REMOVAL OF THE LYMPHATIC GLANDS.

Writing in 1902 Eve said: "The removal of the nearest chain of lymphatic glands, whether palpably enlarged or not, should never be omitted; for it may be taken as a matter of certainty that in a great majority of cases they are infected." In the same paper Eve enforces this lesson by recording a case of melanoma of the palm in which, although the axillary glands were not palpably enlarged, they were

⁹ Heath, Transactions of the Pathological Society, 1863, p. 366.

¹⁰ Arnott, Transactions of the Pathological Society, 1863, p. 366.

infected even to the naked eye. Yet Acton,¹² writing in 1905, found in nearly every case the records of which were available that the primary growth was removed and the lymphatic glands were left!

Admitting the imperative need for removal of the lymphatic glands as a part of the first operation, it must be remarked that in cases which show palpable enlargement of these glands simple excision of the glands is likely to be quite useless. I have shown that permeation of the lymphatic plexus of the deep fascia soon takes place around the infected glands, just as it occurs around the primary tumour. The excision of the glands must therefore be carried out on exactly the same principles as the excision of the primary tumour—that is to say, a large circular area of the surrounding deep fascia must be exposed, dissected up

primary growth, the *two* sets of glands corresponding to the two lymphatic areas involved. The practical importance of these considerations is well illustrated by the following case.

A woman, aged 56 years, came under the care of my friend Mr. Jocelyn Swan, at the Brompton Cancer Hospital. She had had a dark raised mole on the right lateral aspect of the abdominal wall as long as she could remember. It was situated at the level of the umbilicus. At the age of 54 years the mole became ulcerated, with discharge and bleeding; a year later it was removed by her medical attendant. Six months later recurrence took place in the outer end of the scar, and a year after the operation Mr. Swan found the right inguinal gland enlarged to a mass the size of a hen's egg. Their enlargement was first noticed five months after the operation and

FIG. 16.

Diagram to illustrate the method of removing a malignant cutaneous melanoma. The drawing represents a section vertical to the skin surface through the centre of the growth. A represents the primary growth. B, Skin. C, Subcutaneous fat. D, Deep fascia. E, Muscle. The permeated area of the lymphatic system round the growth, represented by blotches and sinuous lines, extends as far as F F' in the skin and as far as G G' in the plane of the deep fascia. H H' are the points where the circular skin incision intersects the section. The dotted line commencing at H H' represents in section the planes of division of the subcutaneous fat, deep fascia, and muscle. The knife should nowhere divide any of the permeated lymphatics; it will almost certainly do so unless the skin flaps are freely undermined.

from its circumference towards the infected glands, and removed in one piece with them. In late cases it may even be right to remove an area of skin over the infected glands, but such cases are probably inoperable.

I am aware of only one case which has been operated upon by the method I advocate, a case recently under the care of my senior colleague, Mr. A. Pearce Gould, at the Middlesex Hospital.

A. D., aged 63, had noticed in July, 1905, a small blue patch "like a wart" on the inner side of his right thigh which began to increase in size. In June, 1906, he noticed a lump in the right groin. On admission, July 6th, 1906, under Mr. Pearce Gould's care, a pedunculated tumour as large as a green walnut was found, ulcerated and dark red in colour below, but of a dark blue-black colour in its upper part. Around its narrow pedicle were one or two pigmented patches in the skin. The inguinal glands formed a mass as large as a Tangerine orange. The iliac glands were not palpably enlarged. Mr. Gould performed an extensive operation, removing an elliptical area of skin over the glands and the tumour, freely undermining the skin flaps for about three inches all round, and dissecting away the large exposed area of deep fascia from the underlying muscles and vessels. The anterior part of the sheath of the femoral vessels was taken away, along with the crural canal and the tissue within it. Healing was delayed by some sloughing of the lower skin flap. The defect was remedied by a Thiersch graft. The patient left the hospital on August 9th. In October a lump, fixed to the iliac vessels, was felt in the right iliac fossa. There was no recurrence in the thigh.¹³

SARCOMATA OF LYMPHATIC BOUNDARY ZONES.

A melanotic sarcoma may originate upon or near the line of demarcation of two adjoining lymphatic areas draining into different sets of lymphatic glands. This fact is of great practical importance, for, when permeation round the growth commences, the sarcoma cells, spreading centrifugally from their point of origin, will soon obtain access to the lymphatic trunks of both areas and will be carried embolically to both sets of glands. Thus, for instance, a sarcoma commencing over or near the middle line of the thorax will involve simultaneously the axillary glands on both sides. A sarcoma beginning at some point along a line drawn horizontally through the umbilicus—the line along which the lymphatics draining towards the axilla anastomose with those draining towards the groin—will simultaneously attack by embolism both the inguinal and the axillary glands of the corresponding side. It is therefore necessary in all cases of melanotic sarcoma to consider the relation of the growth to the lymphatic areas. In sarcomata of lymphatic boundary zones it is imperative to remove, along with the

gave rise to an aching pain in the groin. About the same time a small nodule appeared in the upper and outer quadrant of the right breast, and shooting pains were felt in the right shoulder and axilla. This mass became fixed to the skin and to the pectoral fascia. A mass of glands of about the same size as the mass of inguinal glands, and much larger than the lump in the breast, was present in the right axilla. No other enlarged lymphatic glands were present. There was at this time no loss of flesh. Though Mr. Swan considered the case almost hopeless he removed the breast and axillary glands by a Halsted's operation, and subsequently very freely excised the recurrent nodules in the abdominal wall and the enlarged glands in the groin. The inguinal and axillary glands showed melanotic deposit; the other metastases were colourless. Recurrence took place shortly in the right iliac fossa and in the nape of the neck near the occipital protuberance. One or two doubtful nodules were felt in the right axilla. Paralysis of the left leg and arm followed, but proved temporary. The occipital swelling increased in size and gave rise to intense pain, while the other metastases retrogressed and one in the right breast disappeared. The patient died five months after the second operation with pulmonary oedema.

In this case the axillary and the inguinal glands each formed masses of about the same size, so that their simultaneous invasion rests on strong evidence. It is evident that the proper treatment of this case, had Mr. Swan seen it early enough, would have been the free excision of the mole with a surrounding area of deep fascia, and the simultaneous removal of the inguinal and axillary glands of the same side, whether they could be felt enlarged or not. It may, indeed, be said that the malignancy of the mole was not established at the time it was excised, and this raises the question of the clinical diagnosis of malignancy in moles.

THE CLINICAL DIAGNOSIS OF MALIGNANCY IN MOLES.

When a pigmented wart or mole increases in size, ulcerates, or gives rise to bleeding and discharge it should invariably be treated as a malignant tumour. The key to success in the operative treatment of melanotic growths lies in the general adoption of this rule. To wait for the establishment of the diagnosis by palpable enlargement of the regional lymphatic glands is to court disaster. The complete operation for melanotic sarcoma, already described, should be carried out without delay. The removal of the regional lymphatic glands is not a very severe surgical procedure as

¹² H. W. Acton: The Middlesex Hospital Journal, April, 1905.

¹³ Pearce Gould: Archives of the Middlesex Hospital, vol. 42, p. 1.

insurance policy against such a terrible disease. But me surgeons may consider, wrongly in my opinion, that removal of the glands is unjustifiable until conclusive evidence of the malignancy of the tumour has been obtained. For this purpose microscopic examination of a small portion of the primary tumour is often valueless, an innocent mole may present the typical appearance of an alveolar sarcoma. Proof of malignancy can only be obtained by a systematic examination of the whole of the excised piece of tissue at the centre of which lies the suspected mole. Two adjoining diathermic slices are taken, vertically to the skin surface, through the centre of the suspected tumour. Each slice could be about one-eighth of an inch thick. The slices are red, hardened, and cleared. One of them is preserved as a translucent naked-eye specimen; the other, divided into pieces of suitable size, is submitted to microscopic examination. If beyond the limits of the primary growth in the naked-eye specimen any trace of black cords or dots can be seen, and if in the microscopic specimens permeated lymphatics or perivascular infiltration can be detected beyond the obvious edge of the neoplasm, the malignancy of the tumour is shown beyond the possibility of doubt. Removal of the regional lymphatic glands must in such a case be undertaken without delay. If the surgeon waits for obvious enlargement of the lymphatic glands, permeation of their tributary and efferent trunks may probably by that time have carried the disease beyond the reach of his knife.

THE OUTLOOK FOR OPERATIVE TREATMENT.

In the future, as in the past, many cases of malignant cutaneous melanoma will doubtless present themselves for treatment when they have already become inoperable, and to such cases the terrible lines of Fitzgerald's "Omar" may be forcibly applied:—

"The moving finger writes, and having writ
Moves on: nor all your Piety nor Wit
Shall lure it back to cancel half a line,
Nor all your tears wash out a Word of it."

But fortunately we are not in all cases restricted to the helpless recognition of accomplished facts, and even in dealing with malignant melanoma an intelligent anticipation of the trend of events may sometimes avail to stay the finger of Fate. There can be little doubt that the failure of surgery to deal successfully with malignant melanoma of the skin is partly due to causes within the surgeon's control, in other words, to defective methods of operation. The methods still employed in dealing with melanotic growths of the skin are precisely those which years ago gave such deplorably bad results in the treatment of carcinoma of the breast. Formerly the tumour, with a small circumferential area of skin, was cut out from the breast and the axillary glands were removed, if at all, only when palpably enlarged. Even when the glands were excised the surrounding zone of permeated lymphatics in the breast, in the deep fascia, and in the muscles, was left intact to reproduce the disease. Nowadays the improved operation for breast cancer produces prolonged or permanent immunity in about 50 per cent. of cases. And upon the evidence I have laid before you I venture to predict that the application of more thorough and scientific methods to the surgery of cutaneous melanomata will produce a corresponding, though perhaps a smaller, improvement in the results of operation.

NOTES ON 130 CONSECUTIVE EXTRACTIONS OF CATARACT WITHOUT A FAILURE.¹

By CHARLES HIGGENS, F.R.O.S. ENG.,
SENIOR CONSULTING OPHTHALMIC SURGEON, GUY'S HOSPITAL.

The materials for this paper are taken from my private case-books. Most of the operations were performed in nursing homes or in the private ward of Guy's Hospital but a certain number were done in hotels, lodgings, or private houses. The cases are arranged in the order in which I first saw the patients and most of the

operations were performed in the same order but some few were not done till years after I was first consulted. The number of patients is 124, both eyes being operated on in six cases. 127 were nuclear cataracts. The ages of these patients varied between 45 and 100 years, there being one of the latter age; six were 80 years or over. Two patients had cortical cataract; in one, aged 35 years, both eyes were operated on; in the other, aged 40 years, one only was done. The results are: eyes, vision $\frac{1}{2}$ or better, 115; eyes, vision less than $\frac{1}{2}$, 15. Of these the want of sight in seven was due to causes not connected with cataract. Case 1.—Vision $\frac{1}{2}$ and J. 10; high degree of myopia with extensive choroidal changes. Case 2.—Vision J. 10; dense old corneal opacities. Case 3.—Vision J. 10; severe old iritis, closed adherent pupils; iridectomy in both. Case 4.—J. 12; albuminuric retinitis. Case 5.—Vision $\frac{1}{2}$; large hæmorrhage on optic disc. Smaller ones with white patches in macular region. Case 6.—J. 14; old iritis and choroidal atrophy. Case 7.—J. 4; high degree of myopia and extensive old choroidal atrophy. None of these eyes at time of operation could see more than hand movements and some had bare perception of light, so I think I am justified in calling them successful so far as the operation for cataract is concerned. Case 7 is worthy of some further notice: the eye had doubtful perception of light and my note of the case made two years before the operation, when there was but slight lens opacity, says vitreous opacity, much choroidal change, detachment of retina. Vision nil. I operated at the patient's earnest request and the result surprised me. This case and the first of the seven, as well as some others I have seen, lead me to throw out the suggestion that a diseased lens may in some way cause much greater loss of sight than can be accounted for by its opacity alone. In both these cases the improvement of vision after extraction was much greater than I expected.

Some other observers have, I think, noticed the same thing, and I remember Mr. Robert W. Doane mentioning it to me some months ago in connexion with retinitis pigmentosa. The remaining eight cases merely require needle operations. Some of the patients cannot screw up their courage to undergo further operation. Others are satisfied with what sight they have. Case 1, J. 14; Case 2, $\frac{1}{2}$ and J. 6; Case 3, $\frac{1}{2}$ and J. 4; Case 4, J. 8; Case 5, $\frac{1}{2}$ and J. 4; Case 6, J. 12; Case 7, J. 10; and Case 8, J. 14. Of the remaining 115 vision is in 9 $\frac{1}{2}$, in 34 $\frac{1}{2}$, in 40 $\frac{1}{2}$, in 25 $\frac{1}{2}$, in 6 $\frac{1}{2}$, and in 1 J. 4, but the patient was bedridden. I had no large types to examine him with, but he could see all his pictures and objects in his room, and he wrote me that he was very much pleased with the result of the operation.

Of the 130 extractions 83 were performed without iridectomy. Of these 57 had circular, central, or nearly central and more or less moveable pupils. In 23 the pupil was eccentric, five of these required removal of prolapsed iris, and two iridectomy. In three the condition of the pupil was not noted. In 57 eyes the extraction was associated with iridectomy, performed at the time of extraction or previously. In some the iridectomy had been performed before the patients came to me. In others I did the iridectomy for closed pupil, or other result of previous iritis or for corneal opacity, but only once as a simple preliminary to extraction. In two of these 57 eyes division of opaque membrane with Wecker's scissors was required. In 57 eyes needling for opaque capsule was performed, in some more than once. In one case a traction instrument was required for removal of the lens. In no case of the whole 130 was vitreous lost. In six cases glaucoma occurred as a complication. In one an attack of acute glaucoma came on two months after the extraction; it was relieved by sclerotomy, but returned in five days and was again relieved by sclerotomy; 12 days later it reappeared but yielded to eserine and hot bathing. 18 months later vision was $\frac{1}{2}$ and J. 1 but there was some contraction of the field below and to the inner side. 13 months later tension was + 1 and vision was $\frac{1}{2}$ and J. 4. Iridectomy was performed and opaque membrane cut across. Six months later (three and a quarter years after the extraction) vision was $\frac{1}{2}$ but central vision alone remained. Case 2, iritis with glaucoma, for which iridectomy had been performed, occurred many years before the date of extraction. Case 3, acute glaucoma came on a fortnight after a needle operation and was cured by iridectomy. Case 4, acute glaucoma ten months before extraction, was cured by iridectomy. Needle operation eight months after extraction was followed in four hours by attack of acute glaucoma;

¹ This article was accompanied by an excellent table giving a detailed analysis of the main facts of each operation. Mechanical considerations prevented the publication of this table in our columns. The facts recorded are, however, so well summarised by the author that the value of his communication is in no way diminished by the omission of the table.—*Ed. L.*

cured by sclerotomy. Case 5, needle operation, followed by acute glaucoma three months after extraction; cured by iridectomy. Case 6, chronic glaucoma, commenced three months after extraction; cured by iridectomy. A second attack six months later was cured by sclerotomy. In two of these cases the glaucoma followed immediately upon, and was probably caused by, a needle operation. The cases are Nos. 1, 41, 48, 58, 95, 115, all recovered with vision $\frac{1}{2}$ or better.

Astigmatism varying in degree from 0.50 to 8 D. is noted in 74 eyes, and I expect that it occurred in many more, but I do not think I was so careful in looking for it in my earlier cases; had I done so I think it probable that the vision of several cases given as $\frac{1}{2}$ and $\frac{1}{4}$, with simple spherical lenses, might have been raised to $\frac{1}{2}$, $\frac{3}{4}$, or even $\frac{1}{2}$ with compound lenses. The very frequent occurrence of astigmatism after cataract extraction suggests that if it can be produced by an operation, it can be cured by the same means; and it seems to me that the operative treatment of high degrees of myopic astigmatism is a matter requiring attention. In all my cases the astigmatism was in or approaching the vertical meridian, showing that the cornea is flattened towards the incision; so that if an incision were made for the cure of astigmatism, its direction should be at right angles to that meridian of the cornea which it is desired to flatten. I say advisedly myopic astigmatism, because what is done by an incision in the cornea is to cause flattening, and if one were made in a hypermetropic eye it would have to be planned so as to flatten the least hypermetropic meridian, and so would increase the total hypermetropia and the patient would be little if any the better for it; at any rate, he would still have to wear glasses.

The question of performing extraction in one eye, when the other has sufficiently good vision to enable the patient to follow his usual avocations in life without difficulty, seems to be one upon which ophthalmic surgeons are not quite in agreement. I see patients from time to time who have been told the cataract must be removed without delay or that a preliminary operation must be performed at once. In some cases the surgeon has even gone so far as to emphasise the pressing necessity for immediate operation by requesting the patient to wait a few minutes whilst he telephones to his nursing home to inquire if there is a vacant room so that he or she may be taken in at once; and all this when the other eye has vision $\frac{1}{2}$ or better, can read J. 1, and has little or no opacity in its lens. I never recommend extraction in one eye (when the other sees well enough for the patient's requirements), for visual reasons only. I tell him that from that point of view he will gain little or nothing from an operation, but that if he has any other reason for wishing it done I am quite ready to do it. Some people do not like the look of the eye, or others do not like the look of it and decline to employ persons who appears to be blind in one eye. In one case, No. 114 in the list, the right eye had a very visible cataract, whilst the left had vision $\frac{1}{2}$ and no lens opacity. The patient was a handsome woman of 45 years with daughters to take into society, and she did not like either the look of her eye or the remarks other people made about it. I extracted the cataract with the result that not even an expert could have told which eye had been operated on without making a special examination. I have extracted cataract existing in one eye only, for medical men, because their patients noticed it, and I have also done it for persons going abroad for lengthened periods whose sound eye might possibly become useless before their return, and I do it in cases where the lens appears to be undergoing degenerative changes and is likely to become dislocated. There never can be any hurry about a cataract extraction. An eye which has had only perception of light 30 years or more will see just as well after extraction as one that has only been in the same condition 12 months or less. Cases 72 and 89 are instances of this; in the former the eye had been useless 25 years, in the latter 48 years (the cataract was probably congenital), but vision after extraction was $\frac{1}{2}$ and J. 1 in the first, $\frac{1}{4}$ and J. 4 in the second.

The question of extraction in the second eye is also a matter about which the profession does not seem agreed; my practice is not to recommend it in any case where the operation on the first eye has been entirely successful. But should the result of the first operation be unsatisfactory or the eye become damaged from disuse or injury at any time after it, then I strongly advise the patient to have the second eye done. I also extract in the second eye if the patient wishes it, or for reasons the same as those already given

when speaking of cataract in one eye only. In this series have operated on both eyes in six patients. The second was done in five cases by the patient's desire, and in one because the sight of the first eye was lost from detachment of the retina. Two cases are noted of albuminuric retinal one of which died from uræmia four years after the extraction was performed. Diabetes is noted in one, and retinitis dependent on it spoilt the result of what was otherwise an entirely successful operation. How many more my patients had diabetes I do not know, for I never take into consideration when proposing an operation for cataract and do not inquire about it; it makes no difference whatever to the result, except in such rare cases as the foregoing; in quite young subjects who are obviously very ill and who for an operation of any kind.

My method of operating is simple. I use antiseptics the extent of thoroughly cleansing the eye with perchloric solution 1 in 4000 and afterwards with 10 per cent. boric acid solution, which I also use for washing during the operation. For the application of solution and for sponging use swabs of cotton-wool. I have never gone to the extent of shaving the eyebrows, cutting the lashes, and covering the face with a carbolic towel with a hole in it for the eye. If the conjunctiva is in an unsatisfactory condition my best to set it right; if discharge from the lachrymal sac exists I do my best to cure it, and failing that I use canaliculi, as recommended by Dr. Buller of Montreal, as to keep in the discharge until the operation wound has time to heal. Of the 124 patients operated on two had chloroform and one had A.C.E. mixture; the remainder were operated on under local anaesthesia, cocaine being used all. At first I used it of varying strengths, but have some years used a solution of 5 per cent. I am so thoroughly well satisfied with the action of cocaine that I have never tried any other of the local anaesthetics.

I perform my operation in the following manner. The eye having been thoroughly cleansed and cocainised I first pass a silk suture through the conjunctiva below the lower corneal margin; next direct the patient to look downward and having got the eye into the required position draw the suture moderately tight and have it fixed on the cheek by the thumb or finger of an assistant. I use no other fixation. I next draw the upper eyelid upwards sufficiently to expose the upper margin of the cornea. I never use a speculum. I fix the globe by pressing the index finger and steady the globe by pressing the middle finger lightly upon its inner surface with the second finger of the same hand. Then with a Gräfe's knife I make a section in the sclero-corneal junction forming a flap of rather more than one-third of the cornea. As soon as the incision is finished I tell my assistant to let the suture go, he then removes the lens by pressure with the thumb or forefinger applied to the surface of the lower lid, just below the lower margin of the cornea, aided by counter pressure applied in the same manner above the incision. If the pressure is properly applied the incision begins to gape, the iris protrudes, the pupil dilates, and the lens escapes through it. Having removed the bulk of the cataract I take care to press out all cortex, and then if the iris has not returned to its normal position I replace it by rubbing the upper lid lightly upon it and if that does not suffice I push it back with a curette. In some cases pressure through the lid will not cause the lens to escape; in such, I remove it by ligature pressure with the curette applied directly to the eyeball. I never hurry over the operation, but when the lens has been entirely removed and the iris has returned to its normal position I leave the eye exposed to the light for a few moments; by so doing the pupil contracts and remains contracted and the risk of prolapse is lessened.

After the operation I cover both eyes either with a pad of sal alembroth wool and gauze or Gamgee tissue, or a lig specially made for the purpose, secure the pads by a lig bandage, and put the patient to bed, where he remains for three days. I remove the dressing on the second day but reapply it, and afterwards dress the eye every day, but keep both eyes bandaged for a week, without opening either unless there is some special reason for doing so, such as pain, swelling or redness of the lids, or unusual discomfort. Prolapse of the iris occurs to any considerable extent remove it as soon as I find it; small prolapses I leave alone. With regard to iridectomy, I perform it in all cases where there are numerous synechiae or where from any cause expect that the pupil will not dilate sufficiently to allow

the easy escape of the lens, in cases of increased tension, and in all cases where there is a yellowish nodules with clearly concentric, without any definite sub-internal kind of quality which always appears to be having one whichever way the eye is looked into, which is ill-defined and surrounded by a more or less discoloured red. I know the kind of curvature: the cornea is always sticky and difficult to get away. Operations with either or gently model and stain answered gloriously in the cornea, made of which may remain transparent, come away very easily and, though immature, do not need infirmity. In any case where I have commenced operating with the intention of not performing infirmity, I do it if the pupil will not dilate and if after examination the iris cannot be removed or, if removed, seems inclined to prolapse again. If the iris is wounded in making the section, as sometimes happens from the rolling round the edge of the knife, I do an iridectomy, including the wounded portion. In 118 of these cases the section was made upwards. In the two remaining infirmity had been performed down and in one, and down and out in the other, and the section was made in a corresponding direction.

Enkhuizen, W.

THE SUCCESSFUL TREATMENT OF TUBERCULOSIS AND LEPROSY

BY MEANS OF AN ALKALIMETRIC METABOLIC PRODUCT, CHEMICALLY ALTERED OF A BACILLUS DISCOVERED AT BOEHBY (ORANGE RIVER COLONY) IN 1888.

BY R. F. WERNICH, M.D. EDIN.

(A Preliminary Note.)

No attempt will be made to prove that the bacillus in question is, or is not, the common bacillus scrofulae of bodies, body, because the varieties, whatever they may be, cannot alter either the propagation of the remedy or the results obtained; and secondly, because the references made regarding bacillus scrofulae in bacteriological literature are so contradictory that the risk appears a somewhat hopeless one. I try extracts from my notes will be given and a few experiments described from which it will appear that some of the characteristics of this bacillus are those of bacillus scrofulae, while others seem to show that it is a new one. It is impossible, of course, that the latter may have been brought out by growth in peculiar circumstances, or, as I am inclined to believe, in more favourable circumstances. Whatever the case may be, it appears extremely likely that under the designation bacillus scrofulae we are dealing with a group and not a single individual, hence the fact that each investigator has his own set bacillus scrofulae differing in some respects from those of others. To quote literature on this point will be a waste of time; I shall therefore at once proceed to describe the origin and characteristics of the bacillus. It was first obtained at Boehby, Orange River Colony, in 1888, as a gradually pure growth in an infusion of a herb that was supposed to contain an alkaloid. Later, while studying the bacteriology of common wheat meal and bean fermentations, it was again encountered. This time its true home was found and the fact was discovered that it plays a part in practically all spontaneous decompositions or fermentations to which wheat meal or bean is liable. In one case it feeds on the products of decomposition of one germ, and in another it furnishes nutriment for others, while in yet another it enables anaerobic organisms to grow by using up all the oxygen in the medium. The subject of the spontaneous decompositions of wheat meal and bean under varying conditions is a very large one, but also a very interesting one, and I hope at some future time to publish some investigations on the matter.

If a quantity of ordinary refined wheat meal is beaten up into a stiff paste with boiling water and 1 per cent. alkali being taken to its boiling temperature have its full effect so as to destroy the lactic acid germs present as much as possible and this paste is spread out on the sides and bottom of a covered vessel, then after from 12 to 24 hours of incubation at a temperature of from 103° to 105° F., it is found that several spots, varying in size, of a red or pink colour, have made their appearance on the surface of this paste. The vessel must be transferred to the incubator at once and the paste spread out so as to have as large a free

surface as possible. On examining these red spots microscopically they are found to consist of a layer of very large round spores firmly bound together so as to form quite a tough skin. On transferring a bit of this skin thoroughly washed with sterile water so as to free it as much as possible from undesirable micro-organisms, to a suitable medium kept either at room temperature or incubated, the spores will develop into large bacilli which can then be readily isolated by the usual methods. Boiling up for an hour a quantity of bran with five or six times the bulk of water and standard strongly alkaline with bicarbonate of soda will give the same result after two or three days of incubation. Here, however, a uniform white mycelium forms over the whole surface which somewhat rapidly turns red and becomes converted into a tough leathery skin which can be removed entire and which can be fairly roughly handled without breaking. This skin, too, like the red spots on the meal paste, consists of large round spores firmly bound together in a single layer. On growing the bacilli obtained from these spores in various media it is found to possess the following characteristics: 1. The bacillus forms spores which like those of the "dry bacillus" group, will stand at least an hour's boiling. 2. It stains like ordinary saprophytes with the usual alkaline dyes. 3. It is strongly aerobic and grows best in somewhat dilute solutions where when incubated at optimum temperature (from 103° to 105°) it grows from the surface downwards. 4. In some media, to be described later, it forms a filamentous growth at room temperature, but its optimum temperature seems to be between 103° and 105°. It grows well even at 100°. The following differences appear when incubated at 104° and 105°. At 104° F.: (a) the medium becomes cloudy at first and is only cleared up after prolonged incubation or use of alkali; (b) a white mycelium rapidly forms; (c) the bacilli are thin and small; (d) it takes 60 hours to get played out; and (e) a sticky sweet odor is produced like that when growing bacillus scrofulae. At 105° F.: (a) the medium is clarified at once and from above downwards, a heavy precipitate falling in most instances, and the bottom layer of the medium remains germ free and undecomposed until the last; (b) there is no trace of mycelium even after very prolonged incubation—five to six days; (c) the bacilli are large and very broad and there are huge clumps; (d) the process is mostly finished in about from eight to 12 hours; and (e) there is absolutely no odor. 5. A considerable amount of acid is formed by this bacillus, for it is found that in a few to eight grains of granitic soda per gram watery extract of fresh meal, bran or egg albumin qualified with grape sugar, the medium is rendered acid inside 24 hours when incubated at 105° F. and a heavy precipitate of alkali albumin is formed. 6. It bears the presence of a considerable quantity of lactic acid, but all volatile acids—acetic, butyric, etc.—increase with its growth. 7. Its most favourable medium is a diluted wheat bran mash. 8. The rapidity of growth in suitable media is phenomenal. 9. It readily digests coagulated albumin and grows well in both acid and alkali albumin. 10. In suitable glass estimations—after gelatin of neutralized watery extract of ground peas and grape sugar, etc.—it forms circular whitish colonies with a smooth margin. 11. On solid media it forms a wrinkled gelatine and here a neutral or alkaline medium is usually more suitable than an acid one. 12. It digests gelatin. 13. It requires a considerable quantity of sugar for its nourishment. 14. It forms a mycelium under unfavourable conditions: (a) incubation below 100° F.; (b) want of sugar; (c) want of albumin; and (d) no alkaline a medium.

At the time when these experiments were started my object was to find whether it was not possible to prepare artificial anthrax for some of our common germ diseases. These were the early days of bacteriology and the subject then was somewhat in its infancy. Very little was known of anaerobes and their specificity. There were several theories in those days as to how immunity was produced, and, like everybody else, I had my own, which, briefly stated, was as follows. When the organism is attacked by a germ producing any one of the well-known germ diseases the symptoms, etc., are due to the circulation in the blood of a poison—now called toxin—of some sort or another. It was argued that this poison, instead of being entirely thrown off and so allowing the disease to go on indefinitely, was converted, partially at least, into an antitoxin. This conversion was held upon as being entirely of a chemical nature. Now the blood being the great oxygen

cured by sclerotomy. Case 5, needle operation, followed by acute glaucoma three months after extraction; cured by iridectomy. Case 6, chronic glaucoma, commenced three months after extraction; cured by iridectomy. A second attack six months later was cured by sclerotomy. In two of these cases the glaucoma followed immediately upon, and was probably caused by, a needle operation. The cases are Nos. 1, 41, 48, 56, 95, 115, all recovered with vision $\frac{1}{8}$ or better.

Astigmatism varying in degree from 0.50 to 8 D. is noted in 74 eyes, and I expect that it occurred in many more, but I do not think I was so careful in looking for it in my earlier cases; had I done so I think it probable that the vision of several cases given as $\frac{1}{8}$ and $\frac{1}{16}$, with simple spherical lenses, might have been raised to $\frac{1}{4}$, $\frac{1}{8}$, or even $\frac{1}{2}$ with compound lenses. The very frequent occurrence of astigmatism after cataract extraction suggests that if it can be produced by an operation, it can be cured by the same means; and it seems to me that the operative treatment of high degrees of myopic astigmatism is a matter requiring attention. In all my cases the astigmatism was in or approaching the vertical meridian, showing that the cornea is flattened towards the incision; so that if an incision were made for the cure of astigmatism, its direction should be at right angles to that meridian of the cornea which it is desired to flatten. I say advisedly myopic astigmatism, because what is done by an incision in the cornea is to cause flattening, and if one were made in a hypermetropic eye it would have to be planned so as to flatten the least hypermetropic meridian, and so would increase the total hypermetropia and the patient would be little if any the better for it; at any rate, he would still have to wear glasses.

The question of performing extraction in one eye, when the other has sufficiently good vision to enable the patient to follow his usual avocations in life without difficulty, seems to be one upon which ophthalmic surgeons are not quite in agreement. I see patients from time to time who have been told the cataract must be removed without delay or that a preliminary operation must be performed at once. In some cases the surgeon has even gone so far as to emphasise the pressing necessity for immediate operation by requesting the patient to wait a few minutes whilst he telephones to his nursing home to inquire if there is a vacant room so that he or she may be taken in at once; and all this when the other eye has vision $\frac{1}{4}$ or better, can read J. 1, and has little or no opacity in its lens. I never recommend extraction in one eye (when the other sees well enough for the patient's requirements), for visual reasons only. I tell him that from that point of view he will gain little or nothing from an operation, but that if he has any other reason for wishing it done I am quite ready to do it. Some people do not like the look of the eye, or others do not like the look of it and decline to employ persons who appears to be blind in one eye. In one case, No. 114 in the list, the right eye had a very visible cataract, whilst the left had vision $\frac{1}{8}$ and no lens opacity. The patient was a handsome woman of 45 years with daughters to take into society, and she did not like either the look of her eye or the remarks other people made about it. I extracted the cataract with the result that not even an expert could have told which eye had been operated on without making a special examination. I have extracted cataract existing in one eye only, for medical men, because their patients noticed it, and I have also done it for persons going abroad for lengthened periods whose sound eyes might possibly become useless before their return, and I do it in cases where the lens appears to be undergoing degenerative changes and is likely to become dislocated. There never can be any hurry about a cataract extraction. An eye which has had only perception of light 30 years or more will see just as well after extraction as one that has only been in the same condition 12 months or less. Cases 72 and 89 are instances of this; in the former the eye had been useless 25 years, in the latter 46 years (the cataract was probably congenital), but vision after extraction was $\frac{1}{4}$ and J. 1 in the first, $\frac{1}{8}$ and J. 4 in the second.

The question of extraction in the second eye is also a matter about which the profession does not seem agreed; my practice is not to recommend it in any case where the operation on the first eye has been entirely successful. But should the result of the first operation be unsatisfactory or the eye become damaged from disuse or injury at any time after it, then I strongly advise the patient to have the second eye done. I also extract in the second eye if the patient wishes it, or for reasons the same as those already given

when speaking of cataract in one eye only. In this series I have operated on both eyes in six patients. The second eye was done in five cases by the patient's desire, and in one because the sight of the first eye was lost from detachment of the retina. Two cases are noted of albuminuric retinitis, one of which died from uræmia four years after the extraction was performed. Diabetes is noted in one, and the retinitis dependent on it spoilt the result of what was otherwise an entirely successful operation. How many more of my patients had diabetes I do not know, for I never take it into consideration when proposing an operation for cataract, and do not inquire about it; it makes no difference whatever to the result, except in such rare cases as the foregoing and in quite young subjects who are obviously very ill and unfit for an operation of any kind.

My method of operating is simple. I use antiseptics to the extent of thoroughly cleansing the eye with perchloride solution 1 in 4000 and afterwards with 10 per cent. boric acid solution, which I also use for washing during the operation. For the application of solution and for sponging I use swabs of cotton-wool. I have never gone to the extent of shaving the eyebrows, cutting the lashes, and covering the face with a carbolic towel with a hole in it for the eye. If the conjunctiva is in an unsatisfactory condition I do my best to set it right; if discharge from the lacrimal sac exists I do my best to cure it, and failing that tie up the canaliculi, as recommended by Dr. Buller of Montreal, so as to keep in the discharge until the operation wound has had time to heal. Of the 124 patients operated on two had chloroform and one had A.C.E. mixture; the remainder were operated on under local anæsthesia, cocaine being used in all. At first I used it of varying strengths, but have for some years used a solution of 5 per cent. I am so thoroughly well satisfied with the action of cocaine that I have never tried any other of the local anæsthetics.

I perform my operation in the following manner. The eye having been thoroughly cleansed and cocaineised I first pass a silk suture through the conjunctiva below the lower corneal margin; next direct the patient to look downwards, and having got the eye into the required position draw the suture moderately tight and have it fixed on the cheek by the thumb or finger of an assistant. I use no other fixation. I next draw the upper eyelid upwards sufficiently to expose the upper margin of the cornea. I never use a speculum or fixing forceps, but keep the lid in the required position with the index finger and steady the globe by pressing very lightly upon its inner surface with the second finger of the same hand. Then with a Græfe's knife I make a section in the sclero-corneal junction forming a flap of rather more than one-third of the cornea. As soon as the incision is finished I tell my assistant to let the suture go, hold it myself, and lacerate the capsule. I then remove the lens by pressure with the thumb or forefinger applied to the surface of the lower lid, just below the lower margin of the cornea, aided by counter pressure applied in the same manner above the incision. If the pressure is properly applied the incision begins to gape, the iris protrudes, the pupil dilates, and the lens escapes through it. Having removed the bulk of the cataract I take care to press out all cortex, and then if the iris has not returned to its normal position I replace it by rubbing the upper lid lightly upon it and if that does not suffice I push it back with the curette. In some cases pressure through the lid will not cause the lens to escape; in such, I remove it by light pressure with the curette applied directly to the eyeball. I never hurry over the operation, but when the lens has been entirely removed and the iris has returned to its normal position I leave the eye exposed to the light for a few moments; by so doing the pupil contracts and remains contracted and the risk of prolapse is lessened.

After the operation I cover both eyes either with a pad of sal alembroth wool and gauze or Gamgee tissue, or pads specially made for the purpose, secure the pads by a light bandage, and put the patient to bed, where he remains for three days. I remove the dressing on the second day but keep reapplying it, and afterwards dress the eye every day, but keep both eyes bandaged for a week, without opening either unless there is some special reason for doing so, such as pain, swelling or redness of the lids, or unusual discomfort. If prolapse of the iris occurs to any considerable extent I remove it as soon as I find it; small prolapses I leave alone. With regard to iridectomy, I perform it in all cases where there are numerous synechia or where from any cause I expect that the pupil will not dilate sufficiently to allow

rought down without touching the white. It should be thoroughly washed and filtered rapidly, otherwise the lactic acid bacillus described above turns the precipitate blue and sour and it, of course, becomes worthless.

With practice success is fairly uniform in the above, but it could be pointed out that a bluish tinge is superadded in the tannate or indeed a pure blue got in the following circumstances: (1) when mash is too thin (too much top liquor); (2) when incubation is prolonged beyond 14½ hours; and (3) when the secondary fermentation (after straining) is carried beyond three hours. A white tannate only is got (1) when incubation is much below 125°; (2) when a cold water secondary fermentation is made, that is, when we do not paralyze the lacto-acetic acid bacilli; and (3) when the tannate is altered too slowly it is turned sour and white by lacto-acetic acid bacilli. The white is useless and the tannate is nearly so.

D. Secondary fermentation of a saccharified soured bran mash.—In this method, which yields the best product we saccharify in exactly the same manner as the distiller saccharifies his malt mash, only we use bran in place of great malt. The saccharified mash when cooled to 130° is then inoculated with a pure culture of the bacillus 50 hours old and grown in a material like green malt wort, &c., and incubated for from 14 to 24 hours at 126°. The distiller does not of course prepare his saccharified mash for this purpose, but either lets it sour spontaneously at 122° or inoculates it with a pure culture of the distillery lactic acid bacillus (*bacillus acidificans longissimus*, Lafar, *bacillus Delbrückii*, &c.). The soured mash is then used for the cultivation of yeast. In the case under consideration the object is to get the bacillus to grow to a certain extent at least along with the lactic acid germ which appears spontaneously in our incubated saccharified bran mash. When the mash is now diluted with an equal part of cold water (boiling water is unnecessary here), strained, and allowed to stand, a "secondary fermentation" takes place, the bacillus growing at an enormous rate, and the rods and filaments formed here are the biggest objects in the shape of bacteria that I have ever seen under a microscope. As a consequence the supernatant liquor quickly becomes dark sherry-brown and clear. Precipitation is made after six hours but quite a good precipitate is got after three. There is no undigested stuff now, consequently we can use excess of tannic acid; there is therefore no white precipitate to avoid and when the experiment succeeds there is no risk of getting blue even on incubating the mash for 43 hours and allowing the secondary fermentation to go on 24 hours. However, under faulty methods we here again find "blue" creeping in as in C. The above method does not always succeed, and I frankly confess that in my hands failure is very much more common than success. I shall therefore fully describe the appearance and characteristics of the mash as well as of the tannate when successful, so that anyone repeating this work may know what to strive after. The mash is perfectly "quiet"—that is, there is not a gas bubble anywhere. The supernatant liquor is dark sherry-brown and clear. There should be no trace of top growth (*zoogloea*). It has a feeble but pleasant sour smell. The liquor of the mash itself effervesces strongly on adding sodium bicarbonate. Tannic acid gives with the top liquor a white, turning at once a beautiful "pink blue," which rapidly settles in a clear liquor from which no further precipitate can be got with anything. On adding tannic acid to the expressed liquor of the mash itself a permanent white granular precipitate is given (gluten altered by lactic acid germ). The tannate got from the secondary fermentation is like that of the top liquor, a "pink blue," but the colour is the only resemblance, for there are several differences between the two. The growth in the top liquor being a practically pure one, it is feeble in action, like all pure growths. In the mash itself, however, the lactic acid germ grew well and furnished the necessary albuminoid pabulum which the bacillus converts into the remedy. The top liquor tannate crumbles to pieces, small cubes, when dry, while the tannate of the secondary fermentation is a material almost as hard as horn, breaks with a vitreous fracture, and when a small piece is held up against the light it is found to be transparent and red like a piece of red glass. The effect of this material on a leper is marvellous. When pulverised it is bright red.

Another way to proceed is to copy F, that is, sour for about 24 hours a saccharified bran mash by means of a pure culture of a lactic acid bacillus (*bacillus Delbrückii*) is readily isolated

from soured green malt mash. I have not been able to use the lactic acid bacilli of bran mash for this purpose. Dilute with from one to two volumes of water at 130° F. and add a pure culture of the bacillus grown in green malt wort or ½ per cent. lukewarm salt extract of bran and grape sugar. The medium on which the bacillus is grown here must be acid and vegetable, as I have always failed with A and B and others of the same sort. Another way is to add two volumes of water at 200°, which will now bring up the temperature of the mixture to 158°. Stand open for one and a half hours and inoculate. Here again we do the same thing as the distiller, using a pure culture of the bacillus in place of a pure culture of yeast, as our object is a different one. In my hands this method has not given uniform success either. My difficulty has been to find a wort in which *bacillus Delbrückii* will grow well. The distiller's success is probably due to the fact that he is able to use the "hochdruck" process and so is able to force albumin into solution. The secondary fermentation is therefore often slow and when allowed to stand 24 hours will either give a permanent white tannate or a deep blue one.

E. Salt extract of fresh meat.—If a ½ per cent. salt-water, cold 24-hour (or less) extract is made of fresh minced meat and a few drops of a culture such as B are added and left standing at room temperature a peculiar phenomenon is observed. A fulminating growth, I can use no other word, takes place here, just as in a diluted soured mash. In 15 minutes growth is visible to the naked eye, and in three hours numerous white round masses of various sizes have formed which gradually run together. In a deep vessel some of these masses will run to the surface and form a layer very much like pus; in a shallow vessel, however, they settle to the bottom. The top liquor is rapidly cleared up. In six hours the whole process is finished. These masses consist of myriads of bacilli bound together by a soft material which is really a precipitate formed from one or other constituent held in solution by the extract. I do not think that the material is a secretive product of the bacilli and I do not therefore look upon them as *zoogloea* masses. Tannic acid gives a permanent white precipitate here, with no tendency to colour up. It was once administered to a leper without any effect. The same thing is seen in lukewarm extracts, but the temperature must be below the coagulating point of myosin. When the fermented liquor is boiled no precipitate is given, showing that the albumin in solution had been used up.

F. Lactic acid and salt extract of meat.—This is more or less an imitation of D using lactic acid in place of the lactic acid bacillus, and meat and grape sugar in place of the saccharified bran mash. Make a 24-hour cold extract of fresh minced meat with water containing ½ per cent. salt and eight minims per pound of acid lactic. Filter. Add 2 per cent. of grape sugar. Inoculate with a few drops of pure culture of the bacillus from A or B. A very rapid growth is set up at once at room temperature, which becomes visible after 15 minutes. In two hours there is a heavy deposit and small lumps continue to settle down. In five hours, more or less, it is completely played out and the medium now consists of a clear brown liquor, with a heavy deposit at the bottom of the vessel. The process is therefore absolutely analogous to the secondary fermentation in a diluted soured bran mash. As in the soured mash, the extract can be heated up to 158° F. and then allowed to cool to 130° and inoculated, when the same result is got. In all these extracts and mash, however, as in the liquor of a soured mash and, indeed, all media that I have employed so far, if we heat up to boiling point for purposes of sterilisation, even where no precipitate is formed a secondary fermentation is impossible, and we can only then incubate for 60 to 70 hours to get a good result.

Tannic acid gives a white turning blood red in above. Oxidation, however, is slow and is only complete when the tannate is exposed in a moist state to the air in the process of filtration. This fault can, however, be remedied by precipitating in the presence of the oxydases and diastase of bran which can be obtained by making a 158° F. watery extract of bran. I do not want to discuss the question as to whether bran contains an oxydase or not or whether there is such a thing in nature at all, but those who are interested in this question of oxydases may consult Oppenheimer: "Ferments and their Action" (Charles Griffin). It appears certain, however, that translocation diastase, of which bran contains a lot, possesses the power of oxidising some fresh tannates of animal and especially vegetable bodies.

carrier, it was thought that most likely this chemical conversion would be a process of oxidation. The use of our old, and now very much neglected, friend permanganate of potash in disinfecting putrid materials did much to fix this idea in my mind. To isolate and oxidise the toxins of pathogenic micro-organisms was out of the question, but the idea occurred to be that we could utilise the whole army of saprophytes, and possibly the oxidised metabolic products of some of them at least could be utilised to fight bacterial disease. The first germ selected to furnish such a product was the one at present under consideration. To grow this germ and to show that it had produced certain definite chemical compounds was easy enough, but there were difficulties regarding their oxidation. A current of nascent oxygen might or might not do it. Various futile attempts were made which need not be described here. The idea at last occurred that we could fix these compounds to materials capable of combining with oxygen. Pyrogallie acid, tannic acid, &c., were thought of. At last the latter was selected. The bacillus was then grown in various media and after varying periods of incubation the metabolic products were precipitated with tannic acid. The rapid production of a coloured from a colourless precipitate, especially after aeration, satisfied me that I now had an oxidised bacterial product. After satisfying myself that the stuff was perfectly harmless by giving it to dogs and cats and taking it myself in considerable quantities for days, I tried it in a couple of cases of syphilis. Here, however, it appeared to do harm. In one or two cases of tertiary syphilitic ulceration, after a temporary improvement due to removal of inflammatory exudation, the destruction of tissue seemed to go on with greater rapidity. In two cases of syphilitic rupia the crusts rapidly dropped off after a few doses per os and left open bleeding ulcers, which, however, rapidly healed under iodide of potash. A case of scirrhus of the breast was next treated. The whole breast was hard and tense and in the position of the nipple, which had disappeared, was a scooped-out ulcer about two inches in diameter in a circular cartilaginous mass three inches across. After four or five days, taking two doses per os daily, the whole breast collapsed and became soft and flaccid. The cancer mass was now hanging outside the breast in the form of a soft, red, very vascular lump about one-half its former size. The temptation to snip it off with a pair of scissors was very great, but the patient, who was delighted with the result, informed me that she had just received by post a pot of ointment from a cancer curer and she thought that the ointment would do it much better and more thoroughly than the scissors. The patient, who was a visitor, left shortly afterwards and I lost sight of her. From the effect produced in the above cases I thought that most likely leprosy, especially the tubercular form, should derive some benefit from it. Some months afterwards a case of mixed leprosy was brought to the Boshof Gaol Hospital and with the permission of the Orange Free State Government treated with results described hereafter. Encouraged by the results obtained in this case it was not difficult to see that the twin brother of leprosy—namely, tuberculosis, should also yield.

Attempts were now made to prepare the best product possible and for this purpose the bacillus was grown in an endless variety of media. It was soon found, however, that although some media supported the bacillus well little or no active stuff was found in them. For the production of the latter we require albumin just sufficiently broken down to enable it to remain in solution on heating to 158° F. or boiling. Acids and alkalies can be used for this purpose but the best of all is one of the lactic acid bacilli of the distiller. It was also found that a sharp line had to be drawn between albumina derived from the animal or vegetable kingdoms. Preference is to be given to the latter. I can only, therefore, recommend the tannate of the products obtained by growing the bacillus in a diluted soured bran mash. Even a pure growth in a vegetable medium is much inferior to the double growth of the bacillus and the lactic acid bacillus. In this growth of the bacillus and the lactic acid bacillus the bran mash the gluten becomes altered by the lactic acid bacillus to such an extent that it easily goes into solution and now behaves very much like acid albumin. The tannate of unaltered gluten is a nummulary sticky material. The tannate of the altered (acid) gluten is white and granular. The tannate of the product derived by feeding the bacillus on this altered gluten constitutes the remedy and will be on this altered gluten constitutes the remedy and will be described hereafter. The following are some of the media in which the bacillus has been grown.

A. Lactic acid extract of meat.—Make a 24-hour cold extract of fresh minced meat and distilled water containing eight minims per pound of lactic acid and $\frac{1}{4}$ per cent. common salt. Filter. Add 2 per cent. of grape sugar. Sterilise. Inoculate from a recent growth on agar. Incubate at from 120° to 126° F. for from 60 to 70 hours. Filter. Precipitate with solution of tannic acid at once. A white precipitate is given which soon turns to what I have called all along in my notes a "pink-blue"—that is, a precipitate which is bright red or pink by transmitted light, and a bluish or, better still, steel-grey, by reflected light. The best way to examine a precipitate is to let it settle down in a white enamelled dish, when the margin is found to be a bright transparent red and the rest of the surface steel-grey. The precipitate should be excessively fine and not flaky or coarse. All the best products are pink-steel-grey. In impure growths there are various shades of "blue," but the correct one is easily learnt with a little practice. A precipitate here, as in the various bran combinations, may when very impure be blue throughout, there being no pink edge under water. The above precipitate turns black when dried and is readily pulverised.

B. Caustic soda extract.—This can be made either with fresh minced meat or bran and was made on a large scale as follows. Take 1600 grains of common salt, 180 grains of caustic soda, one pound of fresh minced meat, and two pounds of water under 120° F. Cover. Stand at room temperature for 24 hours, after which add 22 pounds of cold water. Stand for six hours. Filter. Put into 16 flasks (four-pound canned fruit bottles with specially constructed covers were used) and add some more water until each flask contains three pounds of liquor. Add 2 per cent. of grape sugar. Sterilise. Inoculate. Incubate at from 120° to 126° for from 60 to 70 hours. Filter. Precipitate at once. The flasks should have a perfectly clear, yellowish-brown liquor with no zooglia and a heavy precipitate at bottom. The tannate here is a fine red.

C. Somewhat crude products but quite good enough for recent acute or old quiescent cases of pure tuberculosis of the lungs, lupus erythematosus, and lupus non-exedens can be made as follows. Digest for from 24 to 30 hours at room temperature half a pound of fresh minced meat or whites of four eggs in 13½ pounds of water and one and a half drachms of lactic acid or three drachms of hydrochloric acid, or, better still, three drachms of hydrochloric acid and about a teaspoonful of papain (Finkler). Put into a 16-pound tin furnished with lid (enamelled is best). Heat up to from 162° to 164° F. Stir in a quantity of bran to form a fairly thick mash. The quantity of bran added should be enough to leave when settled about from two to three inches of free liquor on the surface. Cover tightly with the lid and one or two layers of lint. Put at once into an incubator set to keep up a temperature of 126°. Incubate for 14½ hours. The incubator should now show a temperature of from 126° to 128°. The temperature of the mash itself is from 130° to 128°. Take out and fill up tins at once with boiling water, stirring well as the water is added (best done with Dampfmaischholz of the distiller). Temperature of mash should now be about 152°. Cover tins again. Stand three hours. Strain while still hot into open dishes. Stand three hours exactly. Pour off supernatant liquor, which precipitate. Precipitation requires here a certain amount of care. In the above we have set up a somewhat feeble lactic acid fermentation, but owing to the high temperature very little, if any, lactic acid is formed. The boiling water is added to kill or, at all events, temporarily to paralyse the lactic acid bacilli. The bacillus grows very rapidly after straining but can only be allowed three hours, otherwise a lactic acid bacillus forming very much more acetic than lactic acid which can only be completely killed off by a boiling temperature enters the field. This bacillus, which is a short rod about twice as long as it is broad, feeds on the products of the bacillus which furnishes the remedy and produces a blue tannate.

The tannate obtained in the above process is white turning rapidly into a very heavy excessively fine dark maroon red. It is very gummy and sticks to filter paper. When dry it is pitch black, very hard, and breaks with a vitreous fracture. It is not easily pulverised. In powder form it is again maroon red. The amount of precipitate got is small for the amount of labour. As there is a very large amount of undigested stuff here which gives a permanent white precipitate with tannic acid the latter should be added in very small and dilute quantities. The red precipitate comes down first and with a little practice the whole can be

appeared to have got rapidly worse during the previous months. There were four large patches of infiltration, nodular, on the forehead, one above each eye, two smaller ones between them. Large tubercles occupied nearly the whole of the right lower eyelid and there were several smaller ones on the cheeks, the right side of the nose, &c. There was a large number of maculae on forehead and face, the neck, the body, the arms, and legs. The face was distinctly leonine, the right eye practically closed up. The total number of maculae between 100 and 200, varying in size from one-eighth of an inch to two inches in diameter, and on the front of the shoulder was one measuring two inches by two and a half inches, while on the right side of the neck was one six inches by three and a half inches. The ears were swollen. The muscles of the forearms and hands were atrophied to an extreme degree. There was slight contraction of the fingers. The patient had practically no power in his hands and arms. The skin of the forearms and hands was dry and scaly. The muscles of the legs were atrophied to such an extent that he was unable to get up or walk. There were severe pains, especially at night, in the feet and legs. The skin of the feet and legs was dry and very scaly. Sensation in the feet and the greater part of the legs and hands was absolutely gone. There was very little sensation (patchy) in the forearms. The carpal nerves were swollen and nodular. The nail of the middle toe on the left foot was gone; all the other nails were thick, scaly, and very brittle. The patient refused to be photographed.

Treatment was commenced on July 3rd, 1898. The patient was seen again about a week after, when it was found that the whole face had subsided so that it was less leonine and the tubercles stood out much more distinctly. After another week the leonine aspect of the face was completely gone and the ears presented a peculiar shrivelled-up appearance, the skin being puckered, especially the lobules. The patient was now able to open the right eye fully. It was next noticed that the tubercles and maculae grew darker and darker until all the former and most of the latter became pitch black, those that were exposed to light getting much darker than the protected ones. Next all the parts that were black desquamated. There was also very extensive desquamation in the feet and legs up to the knees. The tubercles threw off thick scabs, but in the case of the maculae the epidermic layer thrown off was very thin. From the very commencement the tubercles diminished in thickness until August 25th when they were flat, puckered, and slightly raised above the surrounding skin. It should be mentioned that this pigmentation and desquamation were repeated several times. The tubercles were soft and pliant so that when the patient wrinkled his forehead the natural transverse wrinkles ran right through them. After the desquamation had come to an end the maculae grew lighter and somewhat reddish in colour, especially those on the neck, face, trunk, and upper arms. They were then soft and shrivelled and most of them were depressed (hollowed out) owing to the complete removal of leprosy infiltration. When the skin was relaxed several of them formed quite a cup-shaped depression. A little later the small maculae were represented by slightly whitish or decolourised patches which could scarcely be seen. The larger ones showed the same change, the decolourising process starting all round the margin, leaving a central red spot which ultimately also disappeared. At this stage it was found that the swelling of the feet and legs was gone, the removal of the swelling from the legs showing that there was very little muscle left; hence the patient's inability to get up.

On August 31st the patient volunteered a statement that sensation was returning in his hands, and on being tested this was found to be correct. There was no sensation as yet in the feet and legs. On examining the toe-nails it was found that they had grown about one-eighth of an inch, there being a piece of new white, smooth nail at the proximal end in each case. On the second toe of the left foot (which was without a nail at the commencement) a new and healthy nail was coming out. On Sept. 24th the patient had considerable power in his hands and was able not only to put on his shirt but also to button it. At the commencement of what little he did was done with the thumb of the right hand. The sebaceous glands situated in areas occupied by tubercles on the face now secreted thick plugs of sebum, and these areas looked much like the maculae at the stage when

all leprosy infiltration had been removed. It should be added, however, that what was taken at the commencement as a single tubercle or infiltrated patch was found to consist of several islands the moment the serous infiltration was removed. On the 28th, so far two changes had been noticed since the patient was put under treatment: 1. Removal (now almost complete) of leprosy infiltration. At first the subcutaneous oedema disappeared by which the feet and legs subsided, and the leonine appearance of the face grew less. The tubercles also stood out more distinctly and became for a time almost pedunculated, and what was at one time considered to be a single infiltrated mass became broken up into several islands. After the above change the tubercles and maculae became absorbed. 2. Restoration of function. (a) Sensation returned in the hands and forearms (later it will be seen in the feet and legs also); (b) muscular power became restored in the hands and forearms (later it

FIG. 1.

Showing result of treatment in a case of leprosy.

will be seen in the legs and feet also); (c) nails grew (restoration of trophic nerves); (d) sebaceous glands in positions occupied by tubercles secreted sebum; and (e) patches of pitch-black smooth and glossy beard grew in the position occupied by maculae on the cheeks.

On Oct. 1st sensation was returning in the legs and on the 10th it had completely returned down to the ankles and on the inside to about two inches below the malleoli. There was no sensation in the feet. On the 20th, during the last fortnight the muscles of the legs, especially the calves, had rapidly re-formed. The right calf was practically normal in thickness and was about twice as thick as it was after the oedema had gone down. The result was that the patient could now, after he had been helplessly paralysed for months, get up with the aid of a stick and walk some little distance by supporting himself against the

There are several other combinations in which the bacillus can be grown, but I have selected from 7000 pages of notes those which indicate the general principles on which we have to proceed to prepare the remedy and which at the same time bring out the chief characteristics of the bacillus.

At this stage nothing can be said as to the nature of the products produced by the bacillus in various media, as the means at my disposal at present do not enable me to work out the matter satisfactorily, but it is hoped that at some future time I shall be able to visit one of the properly equipped laboratories in Europe, where, I have no doubt, it will be an easy matter to study the chemistry of the bacillus and in all likelihood considerably to improve the material with which I have been treating my cases. At the present moment it is sufficient to say that the active material is not produced in all media, as a very free growth can be got in some combinations without a trace of any active material being in evidence as proved by chemical and therapeutic means.

My object in publishing my work in an incomplete form is merely to induce others to take it up and give those finishing touches to it which are beyond the means of an ordinary practitioner in general practice. And while I make this remark I would also like to suggest to those who are more fortunately situated than myself to apply the same principles of precipitation by acid tannic and oxidation with the help, where necessary, of ferments, of ordinary tuberculin and tuberculin T.R. It is possible that the metabolic products of bacillus tuberculosis may be converted into an oxidised tannate with the help of one of the numerous ferments—oxydases, &c.—and so be converted into an antitoxin. As regards the intracellular toxins (tuberculin T.R.) if oxidation is not possible or desirable tannic acid will at least be a means of carrying them uninjured through the stomach into the bowel where absorption readily takes place, and when I am inclined to believe better results will be obtained than by the hypodermic method. The same principles could, of course, be extended to other pathogenic micro-organisms, and there is no reason why the group of harmless micro-organisms should not yield us products as useful as the one that forms the subject of this communication.

Tannic acid may probably also be employed to precipitate the active part or parts of all antitoxin sera, when a more stable product will be got and one more easily administered. The practitioner in a far-off place often has to throw away a life owing to his serum being too old and useless, or to the parents or patient raising objections to hypodermic administration.

Mode of employment.—On a few occasions the hypodermic method was resorted to but owing to the labour and time involved in preparing the material for this purpose, neither of which I could afford in a somewhat busy practice, I have been compelled to administer it by the mouth, air-dried and pulverised. The final product is insoluble in acids but readily dissolves in alkalis. It is administered when the stomach is empty and usually with a little sodium bicarbonate as a precaution. A portion is therefore absorbed in the stomach itself and what escapes destruction there is passed on to the intestine where the alkaline fluids readily cause absorption.

Mode of action.—When injected hypodermically the unaltered albuminoid body produces a thermal reaction with temporary redness and shrinking of lupus and leprotic patches. No permanent benefit, however, is produced.¹ The tannate, on the other hand, acts like a true antitoxin whether given by the mouth or hypodermically. There is here no local or general reaction. This, of course, applies to the product obtained in D. No elevation of temperature is produced; indeed, any pyrexia present—for example, in acute pure tuberculosis of the lungs—is speedily removed. A feeling of general well-being with improvement of appetite and rapid gain in weight, where there has been a loss, soon follow. Another reason for stating that it acts like a true antitoxin is the fact that the changes which take place under administration in a lupus or a leprotic patch are exactly those which we observe in places where nature partially or wholly effects a cure. In a considerable number of cases of lupus and of leprosy I have noticed that the disease progresses by fits and starts. This

is especially true with regard to leprosy. During the quiescent stage nature seems to be able to throw the disease off in some spots at least, and here we have the three phenomena of pigmentation, desquamation, and absorption. The same changes are seen in cases of lupus and leprosy under treatment.

While the same material acts specifically in both leprosy and tuberculosis it is only right to state that the former requires the very best product, such as D, for its successful treatment and for a much longer period. The latter yields rapidly and readily to materials containing merely traces of the active product. The lung (phthisis) yields more readily than the skin (lupus). In fact, in no form of treatment, specific or otherwise, of any diseased condition that I am acquainted with, with the exception of diphtheria antitoxin in uncomplicated (pure) cases of diphtheria, is result more rapid and certain than in cases of pure tuberculosis of the lung treated by this method.

Thus far three classes of cases have been treated successfully: A. tuberculosis of the lungs (including glaucoma in the neck); B. tuberculosis of the skin; and C. leprosy. In treating these cases by two to three doses per os daily find the following changes.

A. Tuberculosis of the lungs.—Consolidation is rapidly cleared up, recent cases taking from seven to 14 days; chronic cases somewhat longer, and other physical signs disappear, so that it becomes impossible to say by percussion or auscultation which lobe it was that was affected. Cough and raised temperature where present disappear, a sense of general well-being is produced, which very often makes the patient lose his or her head, appetite returns, and the patient rapidly puts on weight.

B. Tuberculosis of the skin (lupus) and C. leprosy (all lesions).—The changes produced here are absolutely identical and consist of the three processes of pigmentation, desquamation, and absorption of the infiltrating material. Light-haired persons the patch becomes deep red, in dark-skinned ones mahogany-brown, and in black skins a jet black; desquamation soon follows but the superficial layer is no sooner cast off but pigmentation again appears. Meanwhile absorption is going on slowly, sarcoma infiltration disappearing first and then cellular, and at the end a scar, or more correctly a patch of atrophic skin, is left behind. There is no pigmentation where the rete Malpighii is destroyed and in deep-seated infiltrations where the rete Malpighii is not affected (sometimes seen in leprosy) there is neither pigmentation nor desquamation. Pigmentation is most pronounced in exposed parts.

The cases treated will be taken seriatim as much as possible and the changes which took place carefully described so as to bring out the effect produced. It must however, be distinctly understood that there has been a lot of groping in the dark as the subject was but badly understood at first and I was more often led astray than helped by quite a mass of both English and German bacteriological literature obtained from Europe from time to time. I purposely omit all references therefore in this paper. The result of my difficulties was that the material used from time to time varied much in therapeutic value, in fact, as a great deal of experimental work had to be done all along it follows that at times my patients for weeks at a stretch swallowed stuff that was totally inert. This was especially the case with the first five lepers.

In July, 1898, the late Free State Government very kindly placed five lepers at my disposal and arrangements were subsequently made to put me in charge of the new leper asylum at Bloemfontein and to give me the necessary laboratory appliances to carry on my investigations but the war unfortunately broke out with results known to everybody. It was made clear to all the lepers that they were to be the subjects of scientific experiment, made solely for the purpose of finding a remedy for their terrible disease and in no case was the hope of cure held out. It is strange that in all these cases and a number treated elsewhere subsequently there was not the faintest hesitation; in fact, several willingly offered to sacrifice their lives if thereby means could be found to put an end to the sufferings of others. It is still more strange, however, that in spite of this disregard of life all of them with one exception, where the face was affected, refused to be photographed.

The five Free State cases were the following:—
CASE 1.—The patient was a native male, aged about 40 years. The duration of the disease could not be settled, but

¹ This applies to a whole host of albuminoid bodies, albumoses, &c. See St. Petersburger Medicinische Wochenschrift, 17 (23) April, 1899, "Ueber die Wirkung der Bacterienproteine und der Deutero-albuminose" bei der Lepra." Ed. Soomatz; also Matthes and Krehl, Archiv für Experimentelle Pathologie und Pharmakologie, 1895, vol. xxxvi., p. 437.

retained for five hours for the purpose of examination, and in no case was pyuria found when the urine was microscopically examined. There was no history of the symptoms and signs of gonorrhoea in any of the cases and no history of painful micturition. There was nothing in the family history of these patients to indicate tuberculosis, and none of them presented any sign of tuberculous infection. The exciting cause of the swelling therefore remains unsolved in all five cases and should indicate one of two things, either that the investigation of the disease is exceptionally difficult or that the ordinary causes assigned to it are not so common as supposed. Then, again, the patients were admitted consecutively just as they came for treatment, and, though the number of cases is small, one would have expected that not all the swellings present would have been situated on the right side of the body. In Case 5 the patient presented a second swelling on the left side, but apart from this it was always the glands on the right side that were involved. Such a coincidence does not indicate a clear knowledge of the cause of the disease. The chief mass of glands composing these swellings was formed by the glands of Group 1 and these were the first to become enlarged, whereas if the cause had been genital the enlargement should have been noticed first and chiefly in the glands of Group 2. However, the tracing and mapping out of lymphatics has been partly done from clinical rather than from anatomical experience and to apply the last argument would be to argue a circle. In some cases of bubo occurring in patients on board ship, when there is no possible chance of contagion, often for months at a time, and where the possibility of contagion having occurred is generally freely admitted at once, it is very difficult to discover a source of infection. The cases are as follows:—

CASE 1.—The patient, aged 22 years, was admitted on Dec. 23rd, 1904, and discharged to the convalescent home on Jan. 20th, 1905. He was a pale, thin man, and looked worn and ill when he first came to the hospital on Nov. 24th, 1904, complaining of a painful swelling in the right groin. The swelling had been noticed since Nov. 7th. A complete list of all suspected causes was given and there was no sign of a visible source of infection over the area mentioned above. The diagnosis made from the clinical characters of the swelling was that of inguinal bubo, and since there were present with the swelling redness, heat, pain, tenderness on pressure with fluctuation at the most prominent part of it nitrous oxide anaesthesia was induced and an elliptical incision two inches long was made over the part that yielded fluctuation and about five drachms of pus were evacuated. The relief of the pain was considerable and the patient was instructed to lie in bed at home and have the wound fomented every four hours with boroglyceride, a teaspoonful to a pint of water. He came to the hospital every fourth day for examination and in order to avoid moving the limb he used crutches. On Nov. 30th some enlarged lymphatic glands presented in the wound and were removed, the original incision being enlarged to four inches to improve the drainage. Sections of the glands examined microscopically showed the presence of a small amount of fibrous tissue; there was no caseous area and no sign of sarcoma. On Dec. 21st there was a softened area in the subcutaneous tissue on the inner side of the upper part of the right thigh just to the inner side of the axilla of the internal saphenous vein and under nitrous oxide anaesthesia an incision was made into the softened tissue. Liquefied fat but no pus was found. Both wounds at this stage were fomented every four hours and showed no sign of healing. On the 23rd there was tenderness along the course of the right internal saphenous vein, and the vein was palpably hardened as far as the inner side of the knee. The patient's temperature was 104° F., the pulse was 96 per minute and of full volume, and the respirations were 23 per minute. He was admitted to the hospital and put to bed, his right lower extremity being slightly elevated and flexed at the hip and knee. The fomentations were continued and gave him great relief. The temperature fell in an irregular manner to 93° on the third day after his admission and remained subnormal during the rest of his stay in the hospital. His diet after the first three days was light and nutritious. He took a draught containing quinine and iron three times a day and occasionally an aperient. On Jan. 2nd, 1905, the wounds were dry dressed. On the 5th four ounces of port wine were added to his diet. The wounds, though sluggish, healed on Feb. 11th, the patient being allowed up on Jan. 17th. The change for the better in the patient's general health after his admission to hospital was remarkable. No sign of tubercle was found in the chest on repeated examination. The total duration of his illness from the time the swelling was first noticed until the wound healed was 14 weeks. This patient at the present time, two years after his illness, is in good health. There has been no trouble from the scar which is quite supple and there has been no pain or swelling of the right lower limb.

CASE 2.—The patient, aged 31 years, was admitted on Jan. 28th and discharged to the convalescent home on Feb. 17th, 1905. He was a well-nourished man and came to the out-patient department on Jan. 2nd, 1905, complaining of a painful swelling in the right groin. The swelling had been first noticed the day before. The patient's general condition was good and he had no symptoms or signs of any other disease. Locally there was a tender, irregular swelling, 2 inches by 1½ inches by 1 inch, situated in the right groin. The long axis of the swelling was just below and parallel to, Poupart's ligament. The upper border of the swelling extended about half an inch above the line of Poupart's ligament. No fluctuation could be elicited. There was no sign of infection in the area mentioned before and the patient denied two years. There was no history of gonorrhoea. The treatment locally was by fomentations, with instructions to rest in bed, and

these instructions were carried out. The swelling increased gradually in size, especially at its lower end, and on Jan. 23th the patient was admitted to the hospital. His temperature was 99° F., his pulse was 80, and his respirations were 20. The urine was natural. The swelling now measured 3 inches by 2 inches by 1½ inches, apparently involved chiefly the glands of Group 3, and was adherent to the skin but yielded no fluctuation. It was tender. Under a general anæsthetic the surrounding skin was shaved and prepared for operation and the mass of glands was dissected out through a vertical incision two and a half inches in length made over the most prominent part of the swelling. The internal saphenous vein was found to be involved in the mass; it was ligatured above and below and the intervening portion was removed with the glands. The wound was closed with silk-worm gut except for a small drain and dry dressed. On cutting into the swelling numerous foci of pus were found and a broth culture was taken from one of these. The tube showed no growth on the third day. The mass of glands was of the same consistency throughout and a microscopical examination of a section showed chronic inflammation with foci of necrosis. There were no signs of sarcoma. The wound discharged large quantities of serum through the drainage into the dressings. It mostly healed by first intention and it seemed probable that if the main lymphatic vessels, both afferent and efferent, or as many as could be seen as they joined the glands, had been ligatured the healing of the wound would have been facilitated. The cavity left beneath the skin granulated up from the bottom and the base thus became joined to the skin over it. The place of exit of the drainage finally healed on May 24th. The total duration of the man's illness was nine and a half weeks. This patient at the present time is well. The scar is sound and painless. He has noticed that his right leg swells more than his left when he stands up for long at a time.

CASE 3.—The patient, aged 43 years, was admitted on Jan. 30th and discharged on March 4th, 1905. He first noticed an aching pain in his right groin on Dec. 2nd, 1904, and on examining himself discovered a lump where he felt the pain. On the 19th he came to the surgery. The diagnosis was inguinal bubo and the swelling was fomented. The patient was instructed to rest at home and to continue the fomentations every four hours. There was no history of venereal disease and no source of infection was discovered within the area before specified. On Jan. 7th, 1905, fluctuation could be elicited in the swelling and under nitrous oxide anaesthesia a vertical incision one and a half inches long was made over the most prominent part of it and pus was evacuated. A second incision one inch long was made parallel and to the inner side of the first and drainage was established here as a counter opening. The patient continued at home and fomented the wounds every four hours. Owing to their extremely sluggish appearance and the pain in them and in the leg the man was admitted as an in-patient. At this time (Jan. 30th) the local condition was as follows: There were two parallel vertical incisions in the right groin, the outer one extending upwards over the mid-point of Poupart's ligament and one and a half inches long, the inner one one inch distant from the first and one inch long. The edges of these incisions were thick and not shelving and were dark purple, the purple colour extending into the surrounding skin for half an inch in all directions. Pus was discharged through the incisions and there was some slight thickening apparent beneath them. On the 30th, under general anaesthesia, an elliptical incision was made around the two wounds, giving them a margin of half an inch, and all the skin inclosed by this incision was cut away. The base of the wound left by this proceeding was scraped and the wound was packed with gauze. The ulcer was syringed out with 1 in 4000 biniodine of mercury lotion and dressed once daily. In a week the base of the ulcer was nearly level with the skin and the edges of the skin were shelving and showed a blue line. The ulcer thus became a healing one and healing was complete on March 20th. The patient returned to work on March 4th. The total duration of his illness up to then was 15 weeks. At the present time he is in good health and has had no pain in the scar and no swelling of the right lower extremity.

CASE 4.—The patient, aged 22 years, was admitted on Feb. 28th and discharged to the convalescent home on April 14th, 1905. Six weeks previously to admission he had noticed a swelling in his right groin. The swelling increased gradually in size and on admission there was present in the right groin just below Poupart's ligament an oval mass 3 inches by 4 inches by 1½ inches with its long axis parallel to the ligament. The upper border of the swelling extended just above the line of Poupart's ligament. This mass was connected deeply by a bridge of indurated tissue to a second one situated vertically and measuring 1 inch by 3 inches by 1 inch, and below the inner end of Poupart's ligament. The swellings were diagnosed as superficial to the deep fascia. On March 1st, under general anaesthesia, a vertical incision three inches above and two inches below Poupart's ligament. The swelling was found to be one connected mass of enlarged lymphatic glands and was densely adherent to the common femoral artery and vein, from which it was removed together with the sheath of these vessels. The operation took one hour. The edges of the skin were brought together with silk-worm gut and the cavity was drained and dry dressed. Some of the glands exuded pus as the knife was carried between them and the femoral vessels. The wound after the operation gave considerable pain for 12 hours and the patient's temperature rose from 93° to 102° F. The drainage was therefore excessive exudation of pus. On April 3rd all the skin sutures were removed and the wound was opened up and lightly filled with gauze. There was slight secondary hæmorrhage from the wound on the 5th while the patient was using a bed-pan, but it was easily controlled with plugging. From this time healing was uninterrupted and with tincture of iodine—a process which was not painful. Healing finally took place on May 22nd. The patient returned to work on months. Sections of the glands examined under the microscope showed chronic inflammation. Cultures of pus from the foci in the area of the illness were sterile on the third day. The total duration of the illness was 15 weeks. This patient at the present time is in good health. The scar is sound and painless. There has been no more swelling of the right lower limb.

CASE 5.—The patient, aged 42 years, was admitted on March 4th and discharged to the convalescent home on April 23th, 1905. He had been

wall. The palm and the skin of the back of the left hand were now moist and soft. The thenar and hypothenar eminences of the left hand were rapidly re-forming. There was a slight increase in the interossei of the same hand. The thenar eminence of the right hand was increasing. There was just a slight dryness and scaliness of the outer half of the right palm, otherwise the skin of the right hand was normal. The muscles of the forearms had now attained their normal thickness. The muscular power of the forearms and hands was very good. On the 29th the patient for the first time for five months walked a little distance without any assistance or support and was very proud of it.

On Nov. 2nd the patient walked 20 yards without assistance or support. On the 3rd sensation had returned on the inside of each foot as far as the metatarso-phalangeal joint of the big toe. Beyond a slight puckered condition of the skin there was not a trace of tubercle left. The last traces of maculae were fading away and the beard was growing. The patient's general health, spirits, and appetite were excellent. On the 7th he was photographed and on the 24th he carried a bucket of water to his room.

On Dec. 19th sensation had completely returned in the right foot except in the toes, while it was improving in the left foot. The skin of the feet and toes was much improved. On the 27th sensation in the left foot had completely returned. Both soles were very sensitive. The toes of both feet were still somewhat anæsthetic.

On Jan. 28th, 1899, all the small toes could be freely moved, flexed, and extended (they were completely paralysed at the commencement). The extensor muscles of the big toes were still completely paralysed, so that the big toes dropped. The patient carried a five-gallon paraffin tin full of water and without a handle to his room. On March 3rd sensation had returned in the toes. The skin of the feet and toes was very delicate and thin, but otherwise it was moist, smooth, and normal. The patient had now a complete set of new and normal toe-nails.

On April 1st no trace of disease was left anywhere, except that there was still slight paresis in the extensors of the big toes, the patient being able to raise them about half an inch. The treatment was now stopped and he was kept under observation until the following November, when, by consent of the Free State Government, he was sent to his home. He was seen by five medical friends at various times while under treatment. All Free State lepers were examined and certified by two independent medical men, just as in the case of lunatics, before they were deprived of their liberty.

(To be continued.)

FIVE CASES OF INGUINAL BUBO.

By G. H. COLT, M.A., M.B. OANTAB.,

LATE HOUSE SURGEON TO ST. BARTHOLOMEW'S HOSPITAL.

THE five cases recorded below were admitted into St. Bartholomew's Hospital under the care of Mr. D'Arcy Power, and I am indebted to him for permission to publish them. They are recorded because they are common cases and because the method of treatment in cases of bubo is not as satisfactory as one could wish. It is probable that if it had been possible to admit these patients at once as in-patients to the hospital some of them would have been spared the long illnesses which were their lot. It would have been possible to watch the course of their disease more accurately and to operate if necessary at a time of election rather than be driven to operate by the adverse course of the disease, but it is impossible to admit all such cases as in-patients because of the lack of accommodation.

In the first place it will make the description shorter if the area of infection as a possible cause of inguinal bubo is mapped out. The exact boundaries of any lymphatic area are somewhat indefinite, especially towards the middle line of the body, and the arrangement of the glands and terminal lymphatics is subject to considerable variation, but allowance can be made for this clinically. The superficial inguinal lymphatic glands, as a whole, occupy Scarpa's triangle and include the following three chief sets, named according to their disposition with respect to the saphenous opening.

1. A supero-external or inguinal group situated obliquely, parallel with, and just below Poupart's ligament. There are from four to seven of these glands and when they become enlarged the collective swelling often extends slightly above

the level of Poupart's ligament. Their afferent vessels are derived from the superficial lymphatics of the back and outer part of the thigh and buttock, from the superficial lymphatics of the abdominal wall below the level of the umbilicus, except from those of the lower and inner part of this area, which pass to Group 2, and one or two from the front and outer part of the thigh. The efferent vessels pierce the upper and inner portion of the femoral sheath and pass through the crural canal to the deep femoral or external iliac glands.

2. A supero-internal or pubic group of from two to four glands situated near the pubic spine and to the inner side of the internal saphenous vein. Their afferent vessels are derived from the superficial lymphatics of the lower and middle portions of the anterior abdominal wall, from the upper and inner parts of the thigh, from the skin covering the external genital organs, the perineum, and anus. They also receive lymphatics from the lowest part of the rectum, from the membranous and spongy portions of the urethra, and from the glans penis. The efferent vessels pass to Groups 1 and 2 and through the saphenous opening to the deep femoral and external iliac glands.

3. An inferior or femoral set of from three to six glands grouped vertically around the upper end of the internal saphenous vein. Their afferent vessels come from all the superficial lymphatics of the thigh and leg except from a few on the upper and outer aspect of the thigh which pass to Group 2 and one or two which pass to Group 1, except also from the lymphatics on the outer side of the leg behind the fibular region which follow the course of the external saphenous vein to the popliteal glands and drain an area on the outer border of the foot near the heel. There is an excellent demonstration of these superficial lymphatics in a specimen in the Musée au Filat, in Paris, of a mummified lower limb, which shows that this last-mentioned lymphatic is much smaller than is usually depicted in the textbooks of anatomy. In the specimen referred to there are only two lymphatics of any size in the area on the outer side of the leg which do not pass across the middle line either on the front or the back of the leg to join the lymphatics along the course of the internal saphenous vein. The efferent lymphatics of Group 3 pass *via* the saphenous opening to the deep femoral or external iliac glands.

A fourth group must be mentioned in enumerating the glands in this region. It is named deep femoral and consists of three or four glands situated to the inner side of the common femoral vein and partly in the crural canal. The afferent vessels are derived from the deep lymphatics of the front and outer side of the thigh and knee, from the efferent vessels of the other deep lymphatic glands of the lower limb, from some of the efferent vessels of Groups 1 and 2, and from those of Group 3. The efferent vessels pass through the crural canal to the external iliac glands. In addition some of the deep lymphatics of the lower limb, derived chiefly from the back of the thigh, pass through the glands situated at the great sacro-sciatic foramen to the internal iliac glands and a few reach the same destination *via* the obturator foramen.

When therefore in the description of the cases it is stated that no source of infection was found as a cause of the bubo it is because careful search was made over the whole of the area specified without positive result. The slightest sign of uncleanliness, abrasion, inflamed piles, anal ulcer or fissure, balanitis, posthitis, gonorrhoea, and soft sore was very carefully searched for, and in every case except one (Case 5) was found wanting. In this case the connexion is doubtful in point of time. It may be objected that an abrasion or soft sore, if ever present, had healed some time before the patient came to the hospital. All these patients were in the hospital for periods varying from three to six weeks and during this time it was possible to find out how far they could be trusted to give the histories of their diseases honestly and correctly, and it was also possible to check their statements by questioning their relatives and friends. In every case the presence of a soft sore was denied. Most of these patients were of the better class of hospital patients, and they were all people earning a good livelihood. A soft sore is painful, and a patient who is affected is unable to do his work satisfactorily without advice and treatment. It is also taught that a temporary scar is left when the true skin has been involved. In no case did the patient leave his work until he came with the swelling in the groin and in no case was a sign of soft sore detected, though it was looked for carefully. In no case was there any urethral discharge after the urine had been

when these precautions are taken, the gauze drain is left for 36 hours. At the end of that time the dressing is lightly raised at the upper end and the gauze drain is drawn out. The dressings are quickly replaced and the bandage is firmly re-applied. The skin sutures are removed on the ninth or tenth day and the patient gets up about the fourteenth. When the discharge of serum is copious the wound is dressed more frequently and every effort is made to do this anaerobically. The layer of gauze next the foil is not removed. Should the case have been operated on relatively late in the disease the probability is that the edges of the wound will not heal and that the wound will discharge pus in considerable quantity. The quickest way then is to open it right up and lightly fill it daily with iodoform gauze. In one such case (Case 4) swabbing with tincture of iodine seemed to aid the process of healing and was not painful, but it is difficult to be sure whether the healing was actually more rapid in consequence of the use of iodine.

The advantage of the method outlined above is that in the great number of cases valuable time is saved to the patient. It is probable that his illness will be one of a month or less instead of lasting three months or more. Case 3 is a good instance. In a hospital case also the saving of money would be considerable. These patients are greatly relieved in their minds when the swelling has been removed. They often think it is a rupture of some kind, and have been seen wearing trusses to press on the swelling. Although the whole question is difficult of solution and each case has to be taken on its merits the general impression left by a study of the five cases recorded here is that the best line of treatment to adopt in an average case is that which has just been outlined.

St. Bartholomew's Hospital, E.C.

THE TREATMENT OF PROSTATIC CONGESTION BY ELECTRICAL METHODS.¹

By JOSEPH S. BOLTON, M.D., EDIN., M.R.C.S. ENG.

THE functions of the prostate have not been fully worked out and the causes of its enlargement are but imperfectly understood. That the prostate belongs to the generative rather than to the urinary tract is evident from its embryology and comparative anatomy. Prostatic fluid is probably useful chiefly as an accessory and diluent of the secretion from the testicle. Testicular secretion is alkaline. Prostatic secretion is acid and may therefore be required for neutralisation. Removal of the seminal vesicles and prostate from white rats does not diminish the sexual passion but prevents entirely the fertilisation of the ova. In boyhood the prostate is chiefly muscular. At puberty glandular tissue develops. As old age advances some enlargement is very usual. John Hunter showed by experiment that castration of young animals prevented the development of the prostate and that in adult animals castration caused the prostate to atrophy and waste away. In certain animals, as the mole, the prostate enlarges during the rutting season of the year and shrinks again when this is past. Dogs are very subject to hypertrophy of the prostate and castration has often proved a satisfactory remedy. These facts led Dr. J. William White in 1893 to advocate castration of old men who were suffering from enlarged prostate. This operation, though occasionally successful, never became general. It was disliked by the patients and it was by no means devoid of danger.

Recent investigations with the x rays have shown that this agent has a remarkable effect upon the sexual apparatus, the spermatozoa being destroyed or rendered functionless by its action. It is natural, therefore, to ask the question—Will the x rays by their effect upon the testicles produce any amelioration of the condition of a patient suffering from enlarged prostate? Will the x rays produce an effect similar to castration, without any mutilation of the body or danger to the individual? Before this effect of the x rays upon the testicles had been demonstrated Dr. Moszkowicz of Vienna had been investigating the effects of the direct action of the x rays upon the prostate. He exposed the prostate through a cylindrical rectal speculum, the anus and adjoining parts being protected by a leaden mask. Three applications of 15 minutes' duration on alternate days were given.

The size of the prostate was much diminished and the patients were able to micturate without instrumental aid. Dr. Carabelli treated two patients by the x rays without any rectal tube and with equally good result. But he also protected the surrounding parts with a leaden mask. This protection is unnecessary and also unwise. For the effect of the x rays upon the testicles would certainly tend to increase the beneficial effect.

There are, however, other electrical methods which have been used with advantage in the treatment of enlarged and congested prostate. But before considering these it will be well to remind ourselves of the conditions with which we have to deal, and so far as we may their causes. The conditions are: (1) enlargement of the prostate; (2) congestion of the prostate; and (3) atony of the muscles of the bladder.

It is now generally recognised that enlargement of the prostate takes place in late middle life, but that this enlargement causes no symptoms for some years, not, indeed, until through advanced age the muscular fibre of the bladder loses its tone. Even then but little is noticed to attract attention till some irritant sets up congestion of the prostate, when any accidental overfilling of the bladder may bring about acute retention.

The causes of congestion of the prostate are numerous, coming as they do from the three systems with which it is so intimately connected—the alimentary, the urinary, and the sexual systems. There is a close relationship between piles and congested prostate, and both are frequently attributed to a chill. But the usual cause of congestion is undoubtedly an irritable condition of the urine owing to decomposition through detention behind an enlarged prostate. But sexual irritation must not be forgotten. A man who had no trouble till he reached the age of 75 years attributed his symptoms to the death of his wife which had occurred some months previously and his consequent failure to obtain sexual relief.

A patient presenting himself for treatment for prostatic trouble is usually found to be suffering from piles and congestion of all the parts about the anus. The large submucous veins of the prostatic urethra are engorged with blood and the prostate is like a sponge distended with fluid. The weakened bladder is unable to force the urine through the blocked urethra. The indications for treatment are the relief of local stasis and restoration of the circulation and the improvement in tone of the muscular fibres of the bladder. These indications are met by electrical applications. As electricity will relieve, and in many cases cure, chronic piles, so will it relieve prostatic congestion. Dr. Benham Snow of New York has had considerable experience in treating these cases by static electricity. He affirms that "in electricity we have a certain relief for all cases except those in which a malignant or tubercular process is present, or cases in which there is fluctuation from the presence of pus. The degree of success of the treatment depends upon the amount of hyperplasia or degeneration that has taken place in the structure of the gland. In the early stages of the affection a complete cure is uniform."

I have only two cases of my own to report but they tend to confirm the above conclusions. They were treated with high-frequency currents.

In April, 1906, I was called in by a man, aged 60 years, who was suffering from retention of urine. He had been troubled with enlarged prostate for two years and on several occasions had been obliged to be relieved by the catheter. I drew off his urine, which I found turbid and gritty but free from albumin. He benefited somewhat under urotropine and became able to pass his urine again. But the urine remained unhealthy and there were much scalding and irritation in passing it. The prostate was moderately enlarged and there was much congestion about the anus. He had very little comfort day or night owing to frequent calls to micturate. In May I decided to try the effect of electrical treatment upon him. I passed an electrode into his rectum and by means of the high-frequency current apparatus I electrified him for about ten minutes. This I repeated three times a week. At the early sittings I used a metal electrode but later I used a glass vacuum electrode. Within three weeks a great improvement was manifest, so that on June 15th I note, "he rises only once or twice in the night to pass water, and seldom has any discomfort." Still the urine continued turbid and gritty. On July 6th my note records: "Urine clear and acid." The treatment was interrupted at the end of July for three weeks, but as the symptoms showed some tendency to return it was resumed

¹ The physiology and pathology of this article are taken from an excellent work by Dr. Deaver of Philadelphia on Enlargement of the Prostate.

quite well until Feb. 1st, 1905, when he first noticed a swelling in the right groin. He said that he had been treated for hernia from Feb. 10th to the 24th and during this time some external piles had been removed. There was no history of previous illness, gonorrhoea, or syphilis, and none of sores on the area mentioned before. On admission there was present in the right groin a swelling with its long axis parallel to and one inch below Poupart's ligament and measuring 4 inches by 2 inches by 1½ inches, adherent to the skin which was red and through which fluctuation could be elicited. The upper margin of the swelling extended one and a half inches above the line of Poupart's ligament. There were three palpably enlarged glands in the left groin. The only sign of a possible previous infection was the presence of a small healthy scar situated at the right hand margin of the anus and also the presence of three external piles. The skin between these was healthy and clean. A rectal examination revealed one internal pile and no pain was caused during this examination and none was complained of during or after defecation. The urine was natural. The temperature was 99° F., the pulse was 82, and the respirations were 20. On March 6th, under general anaesthesia, the skin having been prepared, an elliptical incision was made through the skin around the long axis of the swelling and the inguinal lymphatic glands were removed *en masse*. A quantity of pus also escaped. The incision was closed with silk-worm-gut sutures and the cavity was drained in an upward and outward direction and dry dressed. The wound healed by first intention at either end but not at the central part. Healing finally took place on May 14th, 1905. The enlarged glands on the left side subsided without local treatment. The total duration of the illness was 15 weeks. This patient at the present time is in good health. The scar is supple, sound, and painless. There has been no swelling of the right lower limb.

The question that naturally arises from a study of these cases relates to the best method of treatment. It seems that in the case of a patient who is able to get about and go to work the disease does not, as a rule, clear up of its own accord. In such case the disease progresses, pus forms, the pain is great, and by reason of it the patient becomes worn and ill. The abscess is opened and usually healing is slow. These cavities show more periaadenitis than adenitis and the glands exposed come out of the wound whole. The edges of the ulcers are thick, they are not level with the base, which is deep, and the surrounding skin is purple. They thus present a sluggish and not a healing appearance. There is some danger of complications later, such as thrombosis of the internal saphenous vein (Case 1), and secondary hemorrhage (Case 4), and it is possible that the latter might, from the situation of the ulcer, prove exceedingly dangerous to life. In any case when, apart from complications, the disease runs this course the patient is in for a long illness and it greatly facilitates a proper understanding between him and the surgeon if this is explained at the outset. The patient then makes the necessary arrangements and makes up his mind to a long illness and there is no further trouble. On the other hand, when in the early stage the patient is put to bed and any apparent source of infection is treated, the disease may clear up, as in the case of the swelling on the left side in Case 5. It seems reasonable to regard this second swelling as similar in nature to that on the right side. It is said that the exercise of continuous uniform pressure on the swelling aids resolution. It was not tried in the case of these patients because during the early stages they were out-patients. The pressure of a truss is certainly most irritating and pus forms quickly. Absence of movement at the hip-joint seems to be the chief aid to resolution and a rational course to pursue is to put the patient to bed lying on his back with his hip- and knee-joints on the affected side slightly flexed by means of a pillow placed under the knee, to give him a light nutritious diet, to attend to his general health according to the indications, and to measure and record the size of the swelling. The change in size in these swellings is a gradual one, and although the general course can be gauged by palpation it is more certain to outline the mass and measure it and then to repeat the observation some three days later. Moreover, much handling impedes the process of resolution. When once it is clear that the swelling is increasing and not diminishing in size, or when the case does not come under observation until the stage of commencing softening, probably the best thing to do is to dissect out the mass of glands whole, paying attention to the following points, which are emphasised because the operation is a useful one and is not described in books on operative surgery.

The patient is prepared for the anaesthetic and his skin is shaved and prepared as for any operation. The patient lies on his back and is anaesthetised. The thigh on the affected side is extended and an elliptical incision as long as the long axis of the mass to be removed is made over the swelling, care being taken to include in the area of the ellipse rather more than less of the skin over the most prominent part of the swelling. This is advisable for two reasons. In the first place there is often pus beneath where none is previously suspected and the skin is already infected

at its most prominent part. In the second place the removal is going to be free and wide of the glands and there is usually left an ample supply of skin to cover in the wound. When the vertical set of superficial femoral glands is enlarged the incisions are best planned so that their upper and outer ends meet at a point half an inch above the junction of the outer and middle thirds of Poupart's ligament, while their lower and inner ends meet an inch below and an inch to the outer side of the pubic spine. As already mentioned, the outer part of the swelling may extend above the line of the ligament. The long axis of the inclosed ellipse is situated obliquely. These incisions give a very good exposure of all the glands involved and allow drainage in an upward and outward direction, while should pus collect in the lower end the removal of the lowermost stitches allows free drainage. Every case has to be taken on its merits, but the incisions described answer very well for the majority of the cases. The incision having been planned and made, the flaps are dissected back and the glands are removed in one piece so as to have as large a margin of healthy tissue as possible and thus avoid infecting the wound; the possibility of the disease being sarcoma has also to be considered. This dissection is a tedious one and takes one hour to perform. On the inner side the exit of the spermatic cord from the superficial abdominal ring comes into view and the glands often have to be separated from the cord. In the middle line of the limb below Poupart's ligament the common femoral artery and to its inner side the vein are in danger of injury. The glands are usually densely adherent to the femoral sheath, and even when the sheath is removed with them it is impossible to avoid letting out pus, as indeed occurred at this stage in Case 4, although the glands were relatively small. The continuation of the sheath over the crural canal is carefully preserved intact and left *in situ*. The upper end of the internal saphenous vein is ligatured at this stage, clamped, and divided between ligature and clamp. It is usually easier to tie the vein again an inch and a half lower down and to remove the intervening portion with the mass of glands, and this is most conveniently done from above downwards. The lymphatic vessels passing to and from the glands are readily seen in a case taken in hand early. They are clamped serially and tied off and divided between the ligature and the clamp which is left in place, both to prevent infection and to aid the removal of the mass. Catgut is used throughout for the ligatures. A vulsellum forceps should not be used to make traction on the glands, for the liability of infecting the wound from a punctured gland is very great. The glands are generally friable and become torn if much traction is made by means of pressure forceps. Judging from the fact that the saphenous opening and crural canal are the situation through which practically the whole lymph stream passes out from the lower limb the glands here should be disturbed as little as is consistent with the removal of the offending mass. Especially should care be taken not to cut off the lymphatic path at the lower end of the superficial femoral glands and between them and the crural canal if possible is left undisturbed, though the glands here ought to be removed if it is judged at the time that they are diseased. The necessity for this was probably the cause of the oedema of the right lower extremity which followed in Case 4 and lasted for two months and of the intermittent oedema in Case 2. In a case taken in hand early and treated on the lines here given such a necessity would be avoided and the chance of a copious serous exudate from the wound would also at the same time be greatly diminished. The removal of the glands having been accomplished all bleeding points are ligatured, the wound is thoroughly swabbed out with iodoform emulsion—for iodoform has been found of benefit in such cases—a gauze drain is inserted in the upper angle of the wound where the risk of sepsis is least, and the skin is brought together with silk-suture. The line of suture is generally found to worm-gut sutures. The formation of pus in such a case is more copious when air is admitted and it might therefore be better to dress such a wound with sterilised silver foil in the usual way, placing the gauze and wool over this. A firm pad of the wool is advisable because the cavity left by removal of the glands is relatively large, but the pressure on the skin should be quite even. A spica bandage is applied, one turn being taken around the opposite thigh, and the patient is put back to bed.

After-treatment.—When the discharge is slight, as it is

then these precautions are taken, the gauze drain is left for 36 hours. At the end of that time the dressing is lightly raised at the upper end and the gauze drain is drawn out. The dressings are quickly replaced and the drainage is firmly re-applied. The skin sutures are removed on the ninth or tenth day and the patient gets up about the fourteenth. When the discharge of serum is copious the wound is dressed more frequently and every effort is made to dress anaerobically. The layer of gauze next the foil is not removed. Should the case have been operated on relatively late in the disease the probability is that the edges of the wound will not heal and that the wound will discharge pus in considerable quantity. The quickest way then is to open it right up and lightly fill it daily with iodoform gauze. In one such case (Case 4) swabbing with tincture of iodine seemed to aid the process of healing and was not painful, but it is difficult to be sure whether the healing was actually more rapid in consequence of the use of iodine.

The advantage of the method outlined above is that in the great number of cases valuable time is saved to the patient. It is probable that his illness will be one of a month or less instead of lasting three months or more. Case 3 is a good instance. In a hospital case also the saving of money would be considerable. These patients are greatly relieved in their minds when the swelling has been removed. They often think it is a rupture of some kind, and have been seen wearing trusses to press on the swelling. Although the whole question is difficult of solution and each case has to be taken on its merits the general impression left by a study of the five cases recorded here is that the best line of treatment to adopt in an average case is that which has just been outlined.

In certain animals, as the mole, the prostate enlarges during the rutting season of the year and shrinks again when this is past. Dogs are very subject to hypertrophy of the prostate and castration has often proved a satisfactory remedy. These facts led Dr. J. William White in 1833 to advocate castration of old men who were suffering from enlarged prostate. This operation, though occasionally successful, never became general. It was disliked by the patients and it was by no means devoid of danger.

Recent investigations with the x rays have shown that this agent has a remarkable effect upon the sexual apparatus, the spermatozoa being destroyed or rendered functionless by its action. It is natural, therefore, to ask the question—Will the x rays by their effect upon the testicles produce any amelioration of the condition of a patient suffering from enlarged prostate? Will the x rays produce an effect similar to castration, without any mutilation of the body or danger to the individual? Before this effect of the x rays upon the testicles had been demonstrated Dr. Moszkowicz of Vienna had been investigating the effects of the direct action of the x rays upon the prostate. He exposed the prostate through a cylindrical rectal speculum, the anus and adjoining parts being protected by a leaden mask. Three applications of 15 minutes' duration on alternate days were given.

The size of the prostate was much diminished and the patients were able to micturate without instrumental aid. Dr. Carabelli treated two patients by the x rays without any rectal tube and with equally good result. But he also protected the surrounding parts with a leaden mask. This protection is unnecessary and also unwise. For the effect of the x rays upon the testicles would certainly tend to increase the beneficial effect.

There are, however, other electrical methods which have been used with advantage in the treatment of enlarged and congested prostate. But before considering these it will be well to remind ourselves of the conditions with which we have to deal, and so far as we may their causes. The conditions are: (1) enlargement of the prostate; (2) congestion of the prostate; and (3) atony of the muscles of the bladder.

It is now generally recognised that enlargement of the prostate takes place in late middle life, but that this enlargement causes no symptoms for some years, not, indeed, until through advanced age the muscular fibre of the bladder loses its tone. Even then but little is noticed to attract attention till some irritant sets up congestion of the prostate, when any accidental overfilling of the bladder may bring about acute retention.

The causes of congestion of the prostate are numerous, coming as they do from the three systems with which it is so intimately connected—the alimentary, the urinary, and the sexual systems. There is a close relationship between piles and congested prostate, and both are frequently attributed to a chill. But the usual cause of congestion is undoubtedly an irritable condition of the urine owing to decomposition through detention behind an enlarged prostate. But sexual irritation must not be forgotten. A man who had no trouble till he reached the age of 75 years attributed his symptoms to the death of his wife which had occurred some months previously and his consequent failure to obtain sexual relief.

A patient presenting himself for treatment for prostatic trouble is usually found to be suffering from piles and congestion of all the parts about the anus. The large submucous veins of the prostatic urethra are engorged with blood and the prostate is like a sponge distended with fluid. The weakened bladder is unable to force the urine through the blocked urethra. The indications for treatment are the relief of local stasis and restoration of the circulation and the improvement in tone of the muscular fibres of the bladder. These indications are met by electrical applications. As electricity will relieve, and in many cases cure, chronic piles, so will it relieve prostatic congestion. Dr. Benham Snow of New York has had considerable experience in treating these cases by static electricity. He affirms that "in electricity we have a certain relief for all cases except those in which a malignant or tubercular process is present, or cases in which there is fluctuation from the presence of pus. The degree of success of the treatment depends upon the amount of hyperplasia or degeneration that has taken place in the structure of the gland. In the early stages of the affection a complete cure is uniform."

I have only two cases of my own to report but they tend to confirm the above conclusions. They were treated with high-frequency currents.

In April, 1906, I was called in by a man, aged 60 years, who was suffering from retention of urine. He had been troubled with enlarged prostate for two years and on several occasions had been obliged to be relieved by the catheter. I drew off his urine, which I found turbid and gritty but free from albumin. He benefited somewhat under urotropine and became able to pass his urine again. But the urine remained unhealthy and there were much scalding and irritation in passing it. The prostate was moderately enlarged and there was much congestion about the anus. He had very little comfort day or night owing to frequent calls to micturate. In May I decided to try the effect of electrical treatment upon him. I passed an electrode into his rectum and by means of the high-frequency current apparatus I electrified him for about ten minutes. This I repeated three times a week. At the early sittings I used a metal electrode but later I used a glass vacuum electrode. Within three weeks a great improvement was manifest, so that on June 15th I note, "he rises only once or twice in the night to pass water, and seldom has any discomfort." Still the urine continued turbid and gritty. On July 6th my note records: "Urine clear and acid." The treatment was interrupted at the end of July for three weeks, but as the symptoms showed some tendency to return it was resumed

¹ The physiology and pathology of this article are taken from an excellent work by Dr. Deaver of Philadelphia on Enlargement of the Prostate.

quite well until Feb. 1st, 1905, when he first noticed a swelling in the right groin. He said that he had been treated for hernia from Feb. 10th to the 24th and during this time some external piles had been removed. There was no history of previous illness, gonorrhoea, or syphilis, and none of sores on the area mentioned before. On admission there was present in the right groin a swelling with its long axis parallel to and one inch below Poupart's ligament and measuring 4 inches by 2 inches by 1½ inches, adherent to the skin which was red and through which fluctuation could be elicited. The upper margin of the swelling extended one and a half inches above the line of Poupart's ligament. There were three palpably enlarged glands in the left groin. The only sign of a possible previous infection was the presence of a small healthy scar situated at the right hand margin of the anus and also the presence of three external piles. The skin between these was healthy and clean. A rectal examination revealed one internal pile and no pain was caused during this examination and none was complained of during or after defecation. The urine was natural. The temperature was 99° F., the pulse was 82, and the respirations were 20. On March 6th, under general anaesthesia, the skin having been prepared, an elliptical incision was made through the skin around the long axis of the swelling and the inguinal lymphatic glands were removed *en masse*. A quantity of pus also escaped. The incision was closed with silk-worm-gut sutures and the cavity was drained in an upward and outward direction and dry dressed. The wound healed by first intention at either end but not at the central part. Healing finally took place on May 14th, 1905. The enlarged glands on the left side subsided without local treatment. The total duration of the illness was 15 weeks. This patient at the present time is in good health. The scar is supple, sound, and painless. There has been no swelling of the right lower limb.

The question that naturally arises from a study of these cases relates to the best method of treatment. It seems that in the case of a patient who is able to get about and go to work the disease does not, as a rule, clear up of its own accord. In such case the disease progresses, pus forms, the pain is great, and by reason of it the patient becomes worn and ill. The abscess is opened and usually healing is slow. These cavities show more perladentitis than adenitis and the glands exposed come out of the wound whole. The edges of the ulcers are thick, they are not level with the base, which is deep, and the surrounding skin is purple. They thus present a sluggish and not a healing appearance. There is some danger of complications later, such as thrombosis of the internal saphenous vein (Case 1), and secondary hæmorrhage (Case 4), and it is possible that the latter might, from the situation of the ulcer, prove exceedingly dangerous to life. In any case when, apart from complications, the disease runs this course the patient is in for a long illness and it greatly facilitates a proper understanding between him and the surgeon if this is explained at the outset. The patient then makes the necessary arrangements and makes up his mind to a long illness and there is no further trouble. On the other hand, when in the early stage the patient is put to bed and any apparent source of infection is treated, the disease may clear up, as in the case of the swelling on the left side in Case 5. It seems reasonable to regard this second swelling as similar in nature to that on the right side. It is said that the exercise of continuous uniform pressure on the swelling aids resolution. It was not tried in the case of these patients because during the early stages they were out-patients. The pressure of a truss is certainly most irritating and pus forms quickly. Absence of movement at the hip-joint seems to be the chief aid to resolution and a rational course to pursue is to put the patient to bed lying on his back with his hip- and knee-joints on the affected side slightly flexed by means of a pillow placed under the knee, to give him a light nutritious diet, to attend to his general health according to the indications, and to measure and record the size of the swelling. The change in size in these swellings is a gradual one, and although the general course can be gauged by palpation it is more certain to outline the mass and measure it and then to repeat the observation some three days later. Moreover, much handling impedes the process of resolution. When once it is clear that the swelling is increasing and not diminishing in size, or when the case does not come under observation until the stage of commencing softening, probably the best thing to do is to dissect out the mass of glands whole, paying attention to the following points, which are emphasised because the operation is a useful one and is not described in books on operative surgery.

The patient is prepared for any operation. The patient lies on his back and is anaesthetised. The thigh on the affected side is extended and an elliptical incision as long as the long axis of the mass to be removed is made over the swelling, care being taken to include in the area of the ellipse rather more than less of the skin over the most prominent part of the swelling. This is advisable for two reasons. In the first place there is often pus beneath where none is previously suspected and the skin is already infected

at its most prominent part. In the second place the removal is going to be free and wide of the glands and there is usually left an ample supply of skin to cover in the wound. When the vertical set of superficial femoral glands is enlarged the incisions are best planned so that their upper and outer ends meet at a point half an inch above the junction of the outer and middle thirds of Poupart's ligament, while their lower and inner ends meet an inch below and an inch to the outer side of the pubic spine. As already mentioned, the outer part of the swelling may extend above the line of the ligament. The long axis of the inclosed ellipse is situated obliquely. These incisions give a very good exposure of all the glands involved and allow drainage in an upward and outward direction, while should pus collect in the lower end the removal of the lowermost stitches allows free drainage. Every case has to taken on its merits, but the incisions described answer very well for the majority of the cases. The incision having been planned and made, the flaps are dissected back and the glands are removed in one piece so as to have as large a margin of healthy tissue as possible and thus avoid infecting the wound; the possibility of the disease being sarcoma has also to be considered. This dissection is a tedious one and takes one hour to perform. On the inner side the exit of the spermatic cord from the superficial abdominal ring comes into view and the glands often have to be separated from the cord. In the middle line of the limb below Poupart's ligament the common femoral artery and to its inner side the vein are in danger of injury. The glands are usually densely adherent to the femoral sheath, and even when the sheath is removed with them it is impossible to avoid letting out pus, as indeed occurred at this stage in Case 4, although the glands were relatively small. The continuation of the sheath over the crural canal is carefully preserved intact and left *in situ*. The upper end of the internal saphenous vein is ligatured at this stage, clamped, and divided between ligature and clamp. It is usually easier to tie the vein again an inch and a half lower down and to remove the intervening portion with the mass of glands, and this is most conveniently done from above downwards. The lymphatic vessels passing to and from the glands are readily seen in a case taken in hand early. They are clamped serially and tied off and divided between the ligature and the clamp which is left in place, both to prevent infection and to aid the removal of the mass. Catgut is used throughout for the ligatures. A vulsellum forceps should not be used to make traction on the glands, for the liability of infecting the wound from a punctured gland is very great. The glands are generally friable and become torn if much traction is made by means of pressure forceps. Judging from the fact that the saphenous opening and crural canal are the situation through which practically the whole lymph stream passes out from the lower limb the glands here should be disturbed as little as is consistent with the removal of the offending mass. Especially should care be taken not to cut off the lymphatic path at the lower end of the superficial femoral glands and between them and the deep set which in part lie in the crural canal. The crural canal if possible is left undisturbed, though the glands here ought to be removed if it is judged at the time that they are diseased. The necessity for this was probably the cause of the oedema of the right lower extremity which followed in Case 4 and lasted for two months and of the intermittent oedema in Case 2. In a case taken in hand early and treated on the lines here given such a necessity would be avoided and the chance of a copious serous exudate from the wound would also at the same time be greatly diminished. The removal of the glands having been accomplished all bleeding points are ligatured, the wound is thoroughly swabbed out with iodoform emulsion—for iodoform has been found of benefit in such cases—a gauze drain is inserted in the upper angle of the wound where the risk of sepsis is least, and the skin is brought together with silk-sepsis is least, and the skin is generally found to worm-gut sutures. The formation of pus in such lie below Poupart's ligament. The formation of pus in such a case is more copious when air is admitted and it might therefore be better to dress such a wound with sterilised silver foil in the usual way, placing the gauze and wool over this. A firm pad of the glands is relatively large, but the left by removal of the glands is advisable because the cavity pressure on the skin should be quite even. A spica bandage is applied, one turn being taken around the opposite thigh, and the patient is put back to bed.

After-treatment.—When the discharge is slight, as it is

ROYAL ALEXANDRA MILITARY HOSPITAL,
LONDON, S.W.

- (1) A CASE OF ARTERIO-VENOUS ANEURYSM OF THE ORBIT; AND (2) A CASE OF GUNSHOT FRACTURE OF THE FEMUR WITH DIVISION OF THE GREAT SCIATIC NERVE.

Under the care of Major C. G. SPENCER, R.A.M.C., Professor of Military Surgery, Royal Army Medical College.)

CASE 1.—A gunner, aged 23 years, received a blow in the right eye from a fist on June 12th, 1906, at Standerton, Transvaal. He was sitting down at the time and the blow was quite unexpected. The man who struck him was wearing a ring on one finger. An ordinary "black eye" resulted and the skin was not broken. Three weeks later he began to be troubled with "buzzing noises" in the head, which got worse, and on examination six weeks after the injury a pulsating swelling, with thrill and murmur, was detected in the orbit. He was treated by compression of the common carotid and calcium chloride was given internally, but the swelling increased in size and he was invalided to England. On arrival at Netley in November there was marked proptosis of the right eye, with some swelling of the lids and lachrymation. A pulsating swelling of about the size of a hazel-nut projected under the upper eyelid; the pulsation was expansile, there were a distinct thrill and a loud musical whirring murmur, and it seemed that the main bulk of the aneurysm was deep in the orbit, the small swelling being apparently only an offshoot of it. Vision was $\frac{1}{2}$ in each eye, and there was slight diplopia on looking upwards and to the right. The fundus was normal and the conjunctiva was healthy. He was transferred to London on Nov. 29th and on Dec. 5th the right common carotid was ligatured. Pulsation entirely disappeared on tightening the ligature but a slight thrill could still be felt over the right eyebrow. On Dec. 11th the stitches were removed, the wound being healed, and now pulsation was beginning to reappear but was confined to the small prominent swelling and no longer gave the impression of being deep in the orbit. On the 20th a small incision was made through the upper eyelid and the small swelling, which proved to be a fusiform dilated vessel, was dissected out between two ligatures. All pulsation and thrill at once disappeared and he has had no further trouble. At the present time (March, 1907) no trace of the symptoms remains beyond a slight fulness in the right orbit.

CASE 2.—A man, aged 35 years, was admitted to hospital on Oct. 27th, 1905. He had been shot through the right thigh in South Africa on Sept. 19th, 1901, receiving a compound comminuted fracture at the junction of the middle and lower thirds of the femur, the great sciatic nerve being divided. The fracture was treated on a Hodgson's splint and united slowly, union not being complete for three months. At the end of that time there was good union, with one and a half inches of shortening. There were paralysis of the leg muscles and anesthesia in the distribution of the injured nerve. He was invalided to England in January, 1902, and was treated by massage and electricity but suffered from ulcers on the right foot at various times between March, 1902, and the end of 1903. In November, 1903, he was admitted to the Royal Herbert Hospital, Woolwich, where the sciatic nerve was sutured. This operation was followed by partial recovery, but only the internal popliteal division of the nerve regained its functions, the external popliteal division remaining paralysed. As he suffered a good deal of pain in the leg and foot and the foot was useless and liable to ulcers he was desirous of having it removed. On admission there was marked muscular wasting in the leg, which with the foot was colder than the sound leg. The calf muscles and flexors of the toes were contracted and he was unable to

move the ankle or foot, the heel being drawn up and the foot flexed and inverted. There was anesthesia of the outer side of the leg and foot. Owing to the condition of the heel, the outer part of which was anæsthetic, it was considered inadvisable to perform Syme's amputation, so on Nov. 16th, 1905, amputation was done through the malleoli by an internal flap. This gave a very satisfactory result; healing took place by first intention and the resulting stump was very good. He was discharged on Feb. 9th, 1906, wearing a Syme's boot and able to walk well and bear his whole weight on the stump.

Remarks by Major SPENCER.—Case 1 is of interest, as it is very unusual for such a condition to be produced by a blow from a fist. It is, perhaps, doubtful whether ligature of the carotid was really necessary; possibly local intervention would have succeeded, and the patient would in that case have been spared the risk of the major operation, but the appearance of the aneurysm was sufficiently formidable to defer one from attempting to deal with it directly in the first instance.

Case 2 is of interest as illustrating the special vulnerability and slight tendency to recovery seen in the external popliteal nerve, a point noted by Makins.¹ I am indebted to Major F. W. Begbie, R.A.M.C., for the history of this case.

ROYAL ALEXANDRA HOSPITAL FOR SICK
CHILDREN, BRIGHTON.

TWO ABDOMINAL CASES.

(Under the care of Mr. GEORGE MORGAN.)

FOR the notes of the cases we are indebted to Dr. John Allan, late resident medical officer.

CASE 1.—The patient was a male infant, 11 months old, who was sent into hospital on June 28th, 1906, as a case of acute intussusception. The history was that on the evening of June 26th he vomited. He was given a dose of castor oil. The bowels acted twice, some mucus and blood being passed. The child screamed out frequently as if in pain. Vomiting took place after almost every feed. Blood was passed per rectum on June 27th and again at 5 P.M. on June 28th. The medical man who had been called in advised his removal to hospital.

On admission the child was found to be a stout, well-developed infant. The face had a drawn, anxious expression, and he cried out frequently, drawing his legs upon the abdomen. In the intervals he lay quiet in a state of semi-collapse. The abdomen was much distended and attempts to examine it were resisted. On palpation the abdominal muscles were found on guard. The abdomen was very resistant, especially in the upper part of the right side. A tumour could not be definitely made out before an anæsthetic was given. Percussion revealed a resonant note with slight impairment over the right abdomen. The temperature was subnormal, but the pulse was fairly good. About 8 P.M. (which was practically 48 hours after the onset) under chloroform the abdomen was opened in the middle line. An ileo-cæcal intussusception was found and this was easily reduced. The infant was rather collapsed when put back to bed and he did not sleep that night. Ten minims of brandy were given every four hours and saline solution was administered per rectum.

On June 29th the child was very restless all day. A draught containing carbonate of bismuth, bromide of potassium, and tincture of opium was ordered to try to get the child to sleep. He was given one drachm of peptonised milk every hour for nourishment. He did not sleep and was very restless. On the 30th the sedative draught was repeated in the evening and he slept two and a quarter hours after 5 A.M. On July 1st one and a half ounces of peptonised milk were given every two hours. A mixture containing small doses of strophanthus and strychnine was given every four hours. The temperature rose after the operation. At 6 A.M. and 6 P.M. on the three days after the operation the temperature was 103° 2', 103° 2', 103°, 103° 8', 104°, and 102° 8' F. Thereafter it gradually fell to normal and on the evening of July 4th it was just below normal. The bowels moved three times on June 29th and some blood was passed in each of the motions. On the 30th they moved twice and there was a trace of blood each time. On July 4th real broth was given for nourishment and on the following

¹ Surgical Experiences in South Africa, p. 361.

and continued for several weeks longer. The result may almost be described as a symptomatic cure, for though his prostate is still large all his urgent symptoms have gone. He enjoys good health, performs his daily work in comfort, sleeps well at night, but still rises once at least to pass urine. Also there is occasionally a little delay in starting the stream of water.

The other case that I have to report is of quite a different type. The patient's present age is only 54 years and he has been troubled with his prostate for ten years. His profession, that of a minister of the Gospel, subjects him to considerable nervous exhaustion. It was on a Sunday night after preaching that he first became aware of something wrong. He spent a restless night, having to rise frequently to pass urine, which was of a cloudy character. This experience was repeated on many occasions, but it caused him little trouble for several years. About three years ago he went out as a missionary to the West Indies. For the first two years of his sojourn there he was remarkably well, but after this he began to suffer from prostatic cystitis and became so ill that he was obliged to return home. Indeed, his medical attendant sent him home for operation. When he came under my care he was thoroughly broken down in health and looked a perfect wreck, many years older than his actual age. He had almost constant trouble with his bladder, and the slightest nervous strain was sufficient to bring on an acute attack. He would first pass a quantity of clear urine, at frequent intervals; then the urine would become turbid, smaller in quantity, and cause scalding, and this would continue till he was completely worn out. I found on examination that his prostate was somewhat enlarged, hard below, softening gradually off higher up, and somewhat too sensitive to the finger in the rectum. He had piles, both internal and external, and a congested condition of the neighbouring parts. I passed a sound but failed to detect any stone. The passage of the instrument through the prostate caused great pain. Before coming under my care he had been taking urotropine and a buchu mixture. I advised him to try the effect of high-frequency currents. To this he agreed, and I commenced to treat him at the end of September of last year. The improvement in this case was most remarkable. He obtained relief after the first few sittings. His bladder symptoms began to yield at once and soon passed completely away. In a few weeks he showed signs of new life and vigour. He lost the haggard look and his whole aspect was completely changed. Early in December he was able to return to the West Indies.

The editor of *Advanced Therapeutics* in commenting upon this treatment says: "The employment of high potential electricity and mechanical vibration in the treatment of prostatitis will revolutionise the management of this unfortunate condition. The most rational treatment of this affection now is the employment of static currents, applied by placing a metal or glass electrode, either posteriorly in contact with the gland or by the employment of one through the urethra."

We in England are, perhaps, less sanguine than the Americans, but we have good reason to believe that this treatment—which is quite painless and not unpleasant in application and causes no shock, so that it can be borne by the aged and the feeble—will bring relief to many an old man whose life has become a miserable existence but who has not the strength or the courage to undergo a serious operation.

Nottingham.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

ROENTGEN RAYS IN THE TREATMENT OF ULCERATIVE BLEPHARITIS.

By T. L. BUNTING, M.D. EDIN., F.R.S. EDIN.

Schiff and Freund some time ago reported some cases of blepharitis treated by Roentgen rays; since then little seems to have been recorded as to the action of the rays in this condition. The following notes on a very old-standing case may therefore be useful.

A man, aged 25 years, had an attack of measles 16 years ago. This was immediately followed by the blepharitis,

which attacked both eyes. The trouble had gradually got worse and he had had frequent attacks of conjunctivitis and keratitis in both eyes. He had been under treatment many times in the course of the disease, and for the last 18 months before coming to me he had been constantly treated at the Newcastle Eye Infirmary. Mr. A. W. Messer, assistant surgeon to the infirmary, who sent the case to me, informs me that all ordinary methods of treatment had been tried without benefit. The patient came to me on July 6th, 1906. The whole of the four lid margins were then involved, and the ulcerative process covered also both the inner and outer surfaces of both lower lids. The lids were all much swollen and they sometimes bled on being touched. There were no eye-lashes and no scabs, but a constant watery discharge. Conjunctivitis and keratitis were present in both eyes and there was some ulceration of the left cornea. There was constant and often severe pain.

During treatment the eyes were kept closed to protect the conjunctiva from the rays, and the healthy skin was covered by a lead shield with a horizontal slit just large enough to expose the diseased surfaces. The tubes used varied in spark gap from 3½ to 5 inches and gave rays of 3–7 Benoist. Exposures of from eight to ten minutes were given about every five days, each eye being treated separately. After two exposures the pain disappeared and never returned. Epithelium began to form on the right lids after seven, and on the left after nine, exposures, and the margins and outer surfaces then healed very rapidly. In subsequent treatment I drew down the lower lids with sticking-plaster so as to expose their inner surfaces, of which the greater part healed as rapidly as the outer surfaces. But I have been unable to obtain healing of a narrow strip in the depth of the recess where the lids meet the eyeball. In spite of all that one can do by evert the lids the rays can only fall on this strip obliquely, and it seems impossible to give a sufficient dose to it without giving so much as to harm the surrounding parts. The patient has now had 24 exposures to each eye, of which the later ones have been devoted to the attempt to heal this narrow strip.

For all practical purposes the patient is now cured. The external appearance is quite normal except for the absence of lashes. There is no pain and the inflammation of the conjunctiva and cornea has disappeared, so that the patient, who has had to spend the greater part of each previous winter indoors with his eyes shaded, has this winter gone about freely.

Newcastle-on-Tyne.

A CASE OF TURPENTINE POISONING

By GUY H. COLTART, M.B. LOND., M.R.O.S. ENG.,
L.R.C.P. LOND.

At this season of "spring cleaning" the following case may be of interest:—

A girl, aged eight years, after having been exposed to the fumes from newly painted woodwork for nearly a fortnight, was seized on March 10th last with headache, vomiting, and swelling of the left tonsil, causing pain and difficulty in swallowing. There was also pyrexia, her evening temperature being 102.5° F. The next day there was pronounced hæmaturia; the urine was bright red in colour and contained albumin. Her temperature was 99°; the bowels had acted and there was no further vomiting; the tongue was furred. On the 12th the urine was nearly black, having the appearance of stout, and contained nearly one-third albumin; both tonsils were enlarged. Her temperature was 102.5°. In the afternoon she was removed to a nursing home, where her temperature was found to be 103.6° on arrival. On the 13th the patient's tongue was cleaner and she had less difficulty in swallowing, but the tonsils were still swollen. The temperature had fallen to 101.5°. The urine was still very dark and loaded with albumin. From the 14th to the 19th there was a steady improvement, the temperature gradually fell to normal, the albuminuria rapidly diminished, and all swelling of the tonsils disappeared. The patient was removed home on the 19th. The urine still contained a trace of albumin, but in every other respect she was quite well. The treatment consisted of rest in bed in a warm room, milk diet, saline aperients every morning, and a mild diaphoretic mixture. There were four other people living in the house, none of whom was affected in any way by the smell of paint.

Fulham-road, S.W.

optom and not as a disease. There were several forms of enteric; the two most defined were amœbic and bacillary enteric. In amœbic dysentery ipecacuanha might be regarded as a specific, whereas in the bacillary form the drug is of no service. On the other hand, the sulphates were of service in bacillary dysentery. Ipecacuanha had fallen into disrepute because it had been used in bacillary enteric. It was necessary to persevere with large doses of ipecacuanha for a long time. He was accustomed to give large doses for one week and smaller doses for a month. He did not use the drug as a routine treatment in cases of enteritis but he had used it with great benefit in cases of enteritis associated with dysentery. He would, however, use large doses in the treatment of cases of enteritis flowing on amœbic dysentery.—Sir LAUDER BRUNTON said that for a long time quinine was used as a specific for ague without the method of its action being known. Now, however, action on the plasmodium was well known. It would seem probable that ipecacuanha acted in a similar manner in amœbic dysentery. He had himself tried the drug in India in dysentery without any beneficial effect. Other remedies had, however, been equally unsuccessful.—Dr. JOHN ANDERSON said that the possibility of being able to diagnose the preputative stage of hepatitis by an examination of the blood was a matter of the greatest importance. He referred to the nausea and vomiting produced by large doses of ipecacuanha and said he had found that it was to a large extent prevented by the simultaneous administration of chloral hydrate.—Mr. J. CANTILE said that he had frequently seen the temperature subside after the puncture of the liver by the needle even when only blood was withdrawn and he did not feel convinced that the fall in temperature was necessarily due to the administration of the ipecacuanha. He thought that most chronic forms of dysentery were amœbic in origin and that a chronic form of bacillary enteric did not occur. He regarded ipecacuanha as a specific for amœbic dysentery.—Major ROGERS said in reply that he did not think that the liver should be punctured until a full trial had been given to ipecacuanha, for in not a few cases fatal results had followed puncture of the liver.

Major ROGERS also read a paper on a Common Sporadic Seven-day Fever of Indian Ports simulating Dengue. He described a short fever, which was the commonest met with in Europeans in Calcutta, although hitherto returned as either malaria or "simple continued fever," which had been differentiated by himself in the course of a study of 1350 consecutive cases of fever by means of the blood changes and clinical notes during the last two years' work in Calcutta. It began suddenly with severe headache, pains in the back and limbs, and pyrexia of a peculiar "saddle-back" type of from six to seven or slightly more days in the great majority of the cases, but sometimes presenting a continued type which was often mistaken for typhoid fever for a time, especially as it was accompanied by a very slow pulse relatively to the temperature. Just about half the cases were admitted during the terminal rise of temperature of about two days' duration, and as it rapidly fell during the inevitable use of quinine, such cases had been always returned as malaria hitherto, although the slow pulse was typically seen at this stage, and was in marked contrast to the rapid one of malaria during high fever. This seven-day fever had a very definite seasonal incidence during the late hot weather and early monsoon months in Calcutta, and declined just when the principal malarial rise of the year took place at the end of the rainy season, the two fevers together constituting one curve through both seasons and hence had been looked on as malarial. The seasonal prevalence differed totally from that of influenza, which the symptoms of the new fever closely resembled in some respects. It had also been regarded as dengue by some previous writers and quite recently had been stated to be only a sporadic form of that disease, although it was wanting in some of the chief characteristics of that disease, while its temperature curve differed widely from the classical descriptions of dengue both in leading text-books and in the accounts of previous great epidemics in India in 1824 and 1872, as was shown by quotations from the old writers on those outbreaks, so that the fever now described was probably a new one hitherto confused with malaria and dengue, for if it was but a sporadic form of dengue the present descriptions of that disease were quite inadequate to cover it, and would require most extensive modification. A bacillus cultivated from the blood of the seven-day fever cases was also described.—Dr. JOHN ANDERSON said that the

description of the fever given by Major Rogers reminded him of a fever known in India as "ardent fever." This occurred in the hottest part of the hot season and especially in those exposed to the sun. All such patients did well. He did not think that quinine was of any service but bromide was of some use.—Sir PATRICK MANSON said that Major Rogers had set himself a difficult task in the diagnosis of the various fevers in tropical countries. There were a large number of undifferentiated fevers, of which the one here described was one. He did not think that the disease described resembled dengue, of which he had seen a good deal, for in that disease the pains were a marked feature and there was a definite eruption which was frequently followed by desquamation. The fever described corresponded to the simple fever described by Crombie. He mentioned a three-day fever followed by intense mental depression, which occurred at Chital and affected Europeans and Goorkhas, but did not affect Hindoos; these fevers had been designated fever of acclimatisation but they were probably specific fever having a limited distribution.—Major ROGERS replied.

MEDICAL SOCIETY OF LONDON.

Exhibition of Cases.

A MEETING of this society was held on April 8th, Dr. PASTER, a Vice-President, being in the chair.

Dr. C. W. CHAPMAN exhibited two cases of Aneurysm of the Aorta. The first was a case of aneurysm of the third part of the thoracic aorta in a man, aged 37 years. He had been shown at the Medical Society two years ago and the details of the case were recorded in Vol. XXVIII. of the Transactions of the society. The specific history depended solely upon that of a small itching venereal sore which had attracted but little notice and consequently escaped adequate treatment. The case was now exhibited to emphasise further the policy of allowing such patients to undertake light work when the disease is in a quiescent state. This patient had left the hospital three years ago and he had practically continued work up to the present time. In the second case, the patient, aged 41 years, was suffering from Aneurysm of the First Part of the Thoracic Aorta. Pulsation was visible in the second right interspace but it was not well marked. Tracheal tugging was present. The superficial veins of the chest and abdomen were distended, especially on the right side. The right radial pulse could not be felt and the pupil on the same side was contracted. The x ray photograph confirmed the result of the physical examination.—Mr. F. DE HAYLAND HALL discussed the case and referred to a similar one under his own care in which the patient had practically recovered. When distended veins were present it generally indicated an intrathoracic neoplasm.—Dr. PASTER also emphasised the last point.

Dr. J. PORTER PARKINSON exhibited a case of Adiposis Dolorosa associated with Myxedema in a woman, aged 60 years. She had noticed some of the fatty lumps in the arms for ten years and some had appeared recently. She had had much aching and shooting pains in both arms. Both the upper arms were abnormally fat, the circumference being 12½ inches on the right side and 13 inches on the left. There was also a good deal of diffuse fat. The patient also presented atrophy of the thyroid and other signs of myxedema and Dr. Parkinson discussed the possible connexion of this disease with adiposis dolorosa.

Dr. A. F. VOELCKER exhibited a case of Multiple Serositis in a boy, aged nine years. There was no family history of tubercle nor of rheumatism but three people in the same tenement had recently died from tuberclosis and the boy was very frequently with them. The present illness began in December, 1905, when the patient was said to have had an attack of "pneumonia" from which he never recovered. On admission to the Hospital for Sick Children in May, 1906, he was short of breath and cyanosed. 40 ounces of clear, sterile fluid containing numerous lymphocytes but no tubercle bacilli were withdrawn from the right pleura. Three weeks later 20 ounces of similar fluid were removed from the left pleura. A week later ascites developed. During August and September, 1906, he was under the care of Dr. F. J. Poynton in University College Hospital with a definite attack of pericarditis. During October he again had definite pericardial friction, signs of fluid in both pleural cavities, and ascites. The case was probably tuberculous in origin,

day ordinary milk and lime water. There was now no difficulty in getting the child to sleep; indeed, he had generally to be wakened to have his nourishment. On the afternoon of the 6th three stitches were removed, as the wound looked perfectly healed. In the evening the child was found with the abdominal wound right open and several feet of intestine outside the abdominal cavity. The intestine was at once covered with cloths wrung out of sterilised water and under chloroform the intestine, after being drenched with saline solution, was returned to the abdominal cavity and the abdominal wall was stitched in layers. The child had a fairly good night's rest. On the following day the temperature rose to 101.2° and for the next three days it kept slightly above normal. On the 8th he had diarrhoea and was sick frequently. The abdomen was very distended and tender. Albumin water was given for 24 hours. On the 9th whey was given, on the 10th Benger's food made with water, and on the 11th peptonised milk. The diarrhoea and sickness lasted for about 48 hours. The abdominal distension and tenderness likewise soon subsided. On the 16th the infant was having bread and milk and on the 20th he was having full diet for a child of his age. The brandy and stimulants which had been gradually diminished were now stopped and he was given cod-liver oil emulsion. After the catastrophe which followed the removal of the stitches on the first occasion no hurry was displayed in removing sutures this time. It was a fortnight after the operation before the first stitch was removed, and it was over three weeks before all were removed. The child was discharged on August 15th.

CASE 2.—The patient was a school boy, aged ten years, who was admitted to hospital on Dec. 7th, 1906. From the history it appeared that about 9.30 A.M. he was seized when running with severe pain in the right groin and a swelling appeared there. He felt sick but did not vomit. This sickening pain continued and he was taken to the hospital about 2.30 P.M. He walked there, but suffered excruciating agony. He had to be assisted when walking and he limped badly.

On examination the patient was found to be a slenderly built lad of fair muscularity. His face was drawn and anxious-looking, and he moved his right leg very slowly and deliberately. When placed in the dorsal decubitus he lay with his right thigh slightly flexed on the abdomen. A tense globular swelling was found in the right groin. This swelling was exquisitely tender to the touch and there was no impulse on coughing. It could not be reduced. The temperature was subnormal and the pulse-rate was only slightly accelerated. A diagnosis of strangulated inguinal hernia was made and he was admitted to hospital. About 4.30 P.M. an operation was performed and a tightly strangulated right inguinal hernia was found. Though the strangulation occurred only some seven hours previously the bowel was quite dusky and was losing its glistening appearance. The gut was freed and returned to the abdomen and the wound was then closed.

The patient had a fairly comfortable night. On the next morning the temperature was 98° F., and for the five days following the operation it remained subnormal. The pulse-rate was 86 per minute and the respirations were 32 a minute. On Dec. 8th he vomited three times and during the next three or four days he was sick once or twice each day in spite of the most careful feeding. On the day after the operation the bowels moved well after two enemata had been given. Until the 12th his progress was fairly satisfactory, except that he was occasionally sick and he had occasional slight pains in the abdomen, but on that date symptoms of acute mischief developed. He complained of very severe pain in the abdomen and vomited frequently. The abdomen was distended and tympanitic and he had some tenesmus. The bowels remained confined and there had been no action since the 8th. The temperature was 97.8° , the pulse was 80 per minute, and the respirations were 30 a minute. About 7 P.M. the symptoms became even more severe, and he vomited about every half hour. About 11 P.M. an opening was made in the middle line and on carefully examining the abdominal contents a mass like a thickened appendix could be felt in the right iliac region. As this mass was apparently better to attack it through an incision was closed. On examining the mass through an opening in the right iliac fossa it was found to be a commencing intussusception, and a small portion of the gut

which had been previously damaged had become adherent to the abdominal parietes. The invaginated portion of bowel was released, the adhesions were broken down, and the wound was closed. All the acute symptoms were relieved and the patient's progress thereafter was satisfactory. He had no more sickness. On Dec. 14th his bowels moved slightly after an enema had been administered and on the following day they moved well after an enema had been given. Nothing of note occurred during convalescence. He was allowed up about the middle of January of this year and was discharged early in February.

Remarks by Dr. ALLAN.—Both cases are interesting because they had to undergo abdominal section twice in a week. Case 1 helps to prove that success attends prompt laparotomy in intussusception. In Case 2 it is of interest to note that the bowel was distinctly damaged, although the strangulation had occurred only a few hours before. It demonstrates the fact that in cases where the strangulation is tight prompt operative interference is necessary, otherwise there is great risk of gangrene of the strangulated piece of intestine supervening. In this case a damaged portion of bowel became adherent to the abdominal wall and proved an important factor in the causation of the intussusception. I have to thank Mr. Morgan for kind permission to use these notes.

Medical Societies.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

The Early Diagnosis and Cure of the Pre-suppurative Stage of Amoebic Hepatitis.—A Common Sporadic Seven-day Fever of Indian Ports simulating Dengue.

A MEETING of this society was held on April 9th, Mr. J. WARRINGTON HAWARD, the President, being in the chair. Major LEONARD ROGERS, I.M.S., read a paper on the Early Diagnosis and Cure of the Pre-suppurative Stage of Amoebic Hepatitis. He described 16 cases of fever, nearly all accompanied by acute hepatitis and a leucocytosis of a peculiar type, which he regarded as the early stages of hepatitis set up by an active or a latent amoebic dysentery, which commonly passed on to the stage of suppuration and then constituted amoebic abscess of the liver, which was so common in certain tropical countries. In nearly all these cases large doses of ipecacuanha were administered, in spite of the absence of all symptoms of dysentery nearly all of them, with a view to curing the latent disease in the large bowel, which, according to his view, was the cause of the hepatitis present. The result had been a rapid cure of the hepatitis and of the dysentery, and in all present, the early cessation of the fever, and in all probability the prevention of the cases drifting on into the very fatal suppurative stage of the disease. In a few of the cases there were no actual symptoms even of hepatitis, the cause of the fever being entirely obscure, until an examination of the blood revealed the leucocytosis, and led to the adoption of the ipecacuanha treatment, with the result that the fever rapidly ceased as in the other cases. In one third of the cases the hepatitis was so marked that exploratory operation was carried out for liver abscess with negative results, yet after this they cleared up rapidly under the ipecacuanha treatment, which Major Rogers urged should always be resorted to before operative measures were undertaken in every case in which any doubt remained as to whether liver abscess had already formed or not. It was anticipated that the early diagnosis by the blood changes and the prompt adoption of the line of treatment advocated would lead to a considerable reduction in the number of cases of fever, which now frequently drift on into liver abscess, while being treated as malaria or some other disease, and in this way the present loss of life among Europeans, who came early under treatment, from amoebic abscess of the liver might be materially reduced when the methods advocated were generally adopted in the tropics. Sir PATRICK MANSON said that the method of treatment advocated by Major Rogers was of the greatest importance. There were two schools with regard to the treatment of the dysentery, those who believed in the administration of the sulphates and those who advocated large doses of ipecacuanha. Dysentery should, however, be regarded as a

as inflamed in his case, or that the auto-toxæmia from which the patient undoubtedly suffered was of cervical origin. He thought the phlegmasia and other symptoms in Mr. Malcolm's cases were secondary to infection of the pelvic cellular tissue. The disadvantages of the removal of the cervix should be carefully considered. The mortality of pan-hysterectomy was distinctly greater. Taking over 1000 cases collected by Pezzi, of each of these two forms of hysterectomy he found the percentage mortality of pan-hysterectomy was 10.4, whilst the mortality of the subtotal operation was only 7.4. The subtotal operation could be performed more quickly and there was less hæmorrhage and the hæmorrhage was more easily controlled; sepsis was much more likely to occur if the vaginal canal were opened up. The length of the vagina was maintained if the cervix was retained and colpocela could be avoided by drawing the stumps formed by the ligation of the uterine and ovarian vessels together on each side. This procedure was useless in pan-hysterectomy. There remained, too, the question of internal secretion and it was quite certain that such a glandular structure as the cervix must serve one. If organs were to be removed for possible dangers in the future, where was the line to be drawn? He did not think that Mr. Malcolm had made out his case.

Dr. T. W. EDEN said that he had performed a large number of hysterectomies for fibromyoma by the supravaginal method and a small number by the total method, and he was equally satisfied with both. He was not at all convinced by Mr. Malcolm's arguments that the total operation possessed any real advantages over the other. Mr. Malcolm's objections to the supravaginal operation were two in number: (1) the blood-supply of the cervical stump was impaired by the operation and it was therefore more liable to become infected; and (2) the mucous membrane of the cervix was a greater source of danger than that of the vagina. With regard to the first objection it must be recollected that the blood-supply of the cervix consisted of the circular artery from the uterine and anastomosing branches from the vaginal arteries. In the supravaginal operation the uterine arteries were divided above the origin of the circular branches, while the vaginal arteries were uninjured; the blood-supply of the cervix was therefore not affected in any way by this operation. With regard to the second objection he thought that bacteriology showed the vaginal flora to be much oftener pathogenic than those of the cervix. The clinical evidence brought forward by Mr. Malcolm in support of his contention upon this point was singularly unconvincing. The occurrence of localised cellulitis around the stump after the supravaginal operation might be due to faulty technique; he had seen such cases himself and he explained them in that way. On the whole, he was not convinced that there was any practical advantage in the total operation. It was argued that better drainage was obtained by the removal of the cervix, but in ordinary circumstances drainage ought not to be required; it was much better to arrest hæmorrhage completely before sewing over the peritoneal edges. It certainly appeared to him that prolapse of the bladder was more likely to occur after the total operation, especially if vaginal drainage were employed for a few days afterwards. Since it could be more rapidly performed he should continue to prefer the subtotal operation except in special circumstances.

The PRESIDENT said that he had performed total abdominal hysterectomy for fibroids to the entire exclusion of the partial operation for the past six years and agreed with the main conclusions of Mr. Malcolm that total abdominal hysterectomy was superior to supravaginal amputation, but he did not think that Mr. Malcolm had produced much evidence of its superiority. He (the President) had given the points of superiority of the total operation at the Manchester meeting of the British Medical Association, in Albutt, Playfair, and Eden's "System of Gynecology," and in that society. He had not seen any evidence brought forward which led him to modify his opinion as to the superiority of the total operation when performed by Doyen's method. It was superior in that it had a lower mortality (as is shown in Sanger and Herff's extensive statistics¹), it provided for drainage, it gave security against injury to the bladder and ureters and against unrecognised hæmorrhage, and it removed the cervix which might become infected, slough, contain unrecognised malignant disease or develop malignant disease subsequently. It was also less likely to be followed by intestinal obstruction if the peritoneum were closed by a purse-string suture.

He had never seen prolapse or trouble with the bladder caused by the operation. Bumm had noticed these troubles after Wertheim's operation and attributed them to the use of gauze drainage. The President had not employed gauze drainage after abdominal hysterectomy for fibroids for several years past and knew that it was unnecessary and believed it to be injurious. The supposed advantage of the internal secretion of the cervix and the slight shortening of the vagina by the removal of the cervix could not be seriously set off against the above-mentioned advantages. Their importance was disproved by the excellent results of vaginal hysterectomy.

Mr. MALCOLM, in reply, said he was quite aware that his arguments would not be conclusive to those who thought the supracervical the better operation. He had brought forward all the clinical evidence he possessed against the view he advocated as well as that in its favour. Nevertheless, he had come to a very decided opinion, founded on the facts stated, that the complete operation was the better one. Of course, it was open to anyone to say that the complications which arose were due to faulty technique, but every care was taken and the first two cases offered no difficulties of manipulation, so that he himself was confident that so far as he was concerned these cases should have given no trouble. Mr. Doran had pleaded for long after-histories. Mr. Malcolm had not tackled this extremely laborious investigation in a series of cases and it might be that he heard most of his successful operations but he had plenty of long histories in which the results were all he could hope for. He had not met with trouble from weakness of the pelvic floor or from cellulitis around the bladder. He did not pack the vagina.

The following specimens were shown:—

Dr. H. RUSSELL ANDREWS: Sarcoma of the Cervix.

Dr. J. H. DAUBER: Fibromyoma containing a Calcified Fibroid lying free in the Uterine Cavity.

Dr. C. LOCKYER: Primary Tuberculous Salpingitis.

Dr. ROBERT WISE: Placenta from a case of Twins.

MANCHESTER MEDICAL SOCIETY.

Acute Appendicitis.

A MEETING of this society was held on March 27th, Dr. S. MORITZ, the President, being in the chair.

Dr. J. DRESCHFELD opened a discussion on the Diagnosis and Treatment of Acute Appendicitis and, considering that the affection as regards treatment is becoming more and more a surgical one, confined his remarks chiefly to the etiology, symptomatology, and diagnosis of the affection. That inflammation of the appendix was of such common occurrence was, he said, explained by its structure and function. On account of its richness in lymphatics and glandular follicles, the slow peristaltic movements, and the stagnation of secretion owing to the small opening into the cæcum, it formed a favourable soil for the development and growth of micro-organisms, and the presence of faecal matter and concretions might easily lead to ulceration, necrosis, and perforation. Obliteration of the opening or lumen easily occurred and led to dropsy or empyema of the appendix, and its variability in length and position, together with the meagre blood-supply by a small terminal artery, explained the occurrence of twists, kinks of the appendix, and of slough and necrosis. Hence the frequent occurrence of appendicitis in infectious diseases (influenza, typhoid fever, dysentery, &c.) and after even slight traumatism. Appendicitis occurred more frequently in the young and middle-aged, as in the old the appendix, according to Ribbert and others, underwent involution, though in many old people the atrophic condition of the appendix was due to an affection of the appendix which might have occurred earlier in life and remained latent; its diminished frequency in women was, according to some, due to the fact that in the female the appendix was supplied by a second artery running in the ovario-appendicular ligament (Da Cott). Clinically a distinction was made between the acute, chronic, recurring, and latent form. The classification of acute appendicitis into catarrhal, suppurative, ulcerative, perforative, and fulminating forms was not a satisfactory one, as one form might develop from another, and even in the catarrhal form Sahli and others believed that there was a primary focus of pus, and appendices removed by operation early in the catarrhal form had shown the presence of hæmorrhages and small collections of pus. The symptoms by no means corresponded to the pathological changes found, yet appendicitis might be divided into mild and more severe

¹ *Encyclopedia of Gynecology and Gynaecology*, 1900, part 2, p. 51.

though there were no certain evidences. Sodium chloride was at one time excluded from the diet, at another time administered in excess, but without effect in either instance.—Dr. POYNTON remarked that he had observed five cases of multiple serositis, four of which were fatal. Three of the five were of tuberculous origin and these had developed the symptoms, and after death revealed the evidences, of tuberculous meningitis. The remaining two cases were of rheumatic origin and from these the rheumatic diplococcus had been obtained.—Dr. DE HAVILLAND HALL referred to a case of undoubtedly tuberculous origin in which the ascites had improved under daily inunctions of guaiacol ointment (ten minims to the drachm).

Dr. POYNTON exhibited a case of Multiple Exostoses in a boy, aged six and a half years, who had presented certain nodular swellings on the bones of the extremities and trunk, dating almost from birth. There was no definite history of rickets, but the case had at one time been diagnosed as such. An exostosis springing from the head of the left radius had interfered with the movements of supination and pronation.—Mr. H. B. ROBINSON referred to the possible surgical treatment of the left elbow-joint.—Dr. VOELCKER discussed the origin of such lesions and suggested irregular ossification associated with rickets as the cause in this case.

Dr. L. A. CLUTTERBUCK exhibited a case of Infantile. The child, a female, was 14 years of age, but exhibited the anthropometric measurements and weight of six years old. Radiographs were exhibited showing that the retarded development extended to the centres of ossification. The bridge of the nose was depressed but there was no history of syphilis, the child being the eldest of eight healthy children. There were no symptoms of cretinism, microcephaly, achondroplasia, congenital heart disease, or rickets.—The case was discussed by Dr. POYNTON, Mr. ROBINSON, and Dr. PASTEUR.

Dr. F. PARKES WEBER exhibited a case of Chronic Myelocytosis (Spleno-medullary) Leukæmia treated by the Roentgen Rays. The patient was a woman, aged 46 years. There were extreme enlargement of the spleen and only very little enlargement of the lymphatic glands. There was considerable cutaneous pigmentation of the face, trunk, and extremities. The patient began to suffer from pains on the left side of the abdomen about the commencement of 1906. On admission to the German Hospital on Jan. 30th, 1907, the hæmoglobin was found to be only 40 per cent. of the normal and there was leucocytosis. She had been given arsenic and for about one week she was treated by exposure of the spleen, sternum, and both thighs to the Roentgen rays for ten minutes at a time. The white cells diminished in number, but on discontinuing the treatment the white cells began again to increase in number. Dr. Weber also exhibited a case of Great Enlargement of the Liver and Spleen of uncertain origin in a man, aged 42 years, who had been in the tropics, which was discussed by Dr. DE HAVILLAND HALL, Dr. CHAPMAN, and Mr. CAMPBELL WILLIAMS.

Mr. ROBINSON exhibited a case of Multiple Sarcomatous Tumour of the Left Femur in a girl, aged 14 years. Three weeks before Christmas, 1906, she noticed a painless swelling of her left thigh. Since that time it had ached occasionally but not especially at night. The tumour of the thigh involved the lower half of the femur. There was fluid in the knee-joint but no thickening of the synovial membrane. On the inner side of the head of the tibia were some swelling and tenderness and a skiagram showed a deposit in this situation. There were a greatly enlarged hard gland just below Poupart's ligament, some small glands along the iliac vessels, and a hard flattened gland of about the size of a two-shilling piece in the right axilla.—Mr. C. S. WALLACE believed that there were certain evidences in favour of osteomyelitis rather than sarcoma, but, on the whole, he was inclined to support Mr. Robinson's diagnosis.

OBSTETRICAL SOCIETY OF LONDON.

Advisability of Removing the Cervix in Performing Hysterectomy.—Exhibition of Specimens.

A MEETING of this society was held on April 3rd, Dr. HERBERT R. SPENCER, the President, being in the chair.

Mr. J. D. MALCOLM read a paper on the Advisability of Removing the Cervix in Performing Hysterectomy. It was pointed out that after a partial hysterectomy the cervix uteri, with its blood-supply to some extent cut off, and with its narrow central tube lined by mucous membrane which might

be chronically inflamed, offered a favourable nidus for the development of pathogenic micro-organisms in the divided uterine tissue, whilst the provision for drainage of discharges was imperfect. Two cases were recorded in which local signs of insidious septic change in the cervix uteri were accompanied by evidences of irritation elsewhere, one patient suffering very severely from phlegmasia dolens and the other from a painful oedematous swelling in the side and in the joints. Both recovered. Notes of a third case were given, in which, after a partial operation by another surgeon, the cervix was found actively inflamed with a fairly copious muco-purulent discharge from the os and giving rise to much irritation of the lower bowel. A note of all Mr. Malcolm's fatal cases of hysterectomy was given. Excluding malignant cases (two deaths), those treated by the old-fashioned serrencut (eight cases, of which six had already been published in detail), and one of enucleation of a fibroid, there remained six deaths. In two of these large fibroids so involved the cervix that the greater part of it was necessarily removed; in one the normal uterus was partially removed, and in one it was completely removed because in each case it was so incorporated with an ovarian tumour deeply buried in the broad ligament that its removal was easier than leaving it. These four cases died within 48 hours of the operations from the severity of the necessary procedures. In two other cases of panhysterectomy death was due to lung complications. It was held that these cases, although in five of the six the whole uterus was removed, offered no guidance to treatment on the main question raised in the paper. The effects of the various methods on the symptoms of the artificially induced menopause were also regarded as not giving very satisfactory indications for treatment, excellent results having been obtained by all methods. The removal of the cervix was therefore urged on the theoretical consideration that leaving it gave an increased opportunity for the development of septic mischief, and because of the belief that in practice the convalescence was smoother by this method. It was urged that in performing hysterectomy the cervix should be removed, that before operating the patient's health should be made as good as possible, and that no woman should be advised to retain a uterine tumour of any considerable size or which had become definitely prejudicial to her health. These were the points to be attended to with a view to improving the results of this, which was already one of their most successful operations.

Mr. ALBAN H. G. DORAN admitted that Mr. Malcolm had most ably pleaded for panhysterectomy, yet for several reasons, in part admitted by himself, his arguments could hardly persuade them that the so-called "subtotal" operation ought to be abandoned. In the first place the cervix was an important part of the pelvic floor which should not be treated as a negligible quantity by the operator. They knew how safely it could be spared when the body of the uterus had been damaged during the removal of an adherent ovarian tumour had to be sacrificed. In the second place, there was reason to believe that in order to insure the full benefits which should follow the saving of more or less of the ovaries in hysterectomy it was advisable to leave a portion of the endometrium as well; in other words, not only the cervix but a little more of the uterus should be spared. Mr. Doran had brought forward evidence, based upon long after-histories, of 60 subtotal hysterectomies showing the value of this practice. Mr. Doran laid great stress on long after-histories, for a woman convalescent from hysterectomy for fibroid was never so sure of permanent benefit as was a patient convalescent from ovariectomy for a non-malignant tumour. The method of Crawford Thomas should be applied to all series of subtotal and panhysterectomies, and it would be instructive to hear some day of Mr. Malcolm's results after passing a test of that kind.

Dr. AMAND ROUTH did not consider that Mr. Malcolm had proved his contention. Hitherto, panhysterectomy in fibromyomatous uteri had been urged from the point of view that the cervix was apt to become malignant if not removed. It had not, however, been proved that fibroids predisposed to uterine cancer, and still less had it been shown that the cervix was especially prone to malignant changes if fibroids were present in the uterine body. Mr. Malcolm had advocated the removal of the cervix "on the theoretical consideration that leaving it gives an increased opportunity for the development of septic mischief." Dr. Routh thought that this was theory alone, and that Mr. Malcolm had advanced no sufficient proof that the cervix

on a boy, 14 years of age, who, his mother said, had always been an idiot. About Christmas, 1906, he was struck behind the ear, where a lump subsequently arose, and at an operation performed on Jan. 12th this was found to be a suppurating hematoma; the mastoid cells were also trephined, but no particular sign of disease was found. On further exploration a suppurating track was found leading down through the occipital bone from which pus was slowly oozing. On the 5th the skull was trephined and the brain was explored for abscess, but none could be discovered. Five days afterwards the boy died. At the necropsy a large cerebellar abscess, which had opened of itself on the under surface, was found on the right side.

Mr. K. E. L. G. GUNN exhibited specimens of Sarcoma of the Femur and of Tuberculous Disease of the Knee-joint. Both of these cases presented symptoms of chronic inflammation of the knee-joint, which was believed to be tuberculous. In one instance the diagnosis was correct; in the other it was very much mistaken.

Mr. SETON S. PRINGLE read a paper on a Sacro-coccygeal Teratoid Tumour with Formation of Metastases in the Groin. The growth had been removed from a man, aged 57 years, who had first noticed it 35 years previously as a small lump on the middle line behind the anus. Since that time the tumour had grown slowly. At the time of the operation it measured 15 inches over all, from the lower to the upper extremity, and 11 inches from side to side. Two metastatic growths, each of the size of a large hen's egg, were present in the right inguinal region; one of these had appeared 33 years and the other 20 years prior to the time of examination.

Mr. ROBERT J. HARVEY described a case of Cerebro-spinal Meningitis occurring in a girl, aged ten years. While swallowing a piece of liver she choked, and, not getting much relief, she was taken to a hospital where she developed great tenderness down the spine. She passed into a comatose condition; her eyes were open but there was no corneal reflex. She died the same night. On the next morning Mr. Harvey drew off some cerebro-spinal fluid by lumbar puncture. The slides which he had prepared showed a diplococcus in great numbers, even in the original fluid. They were distinctly non-Gram staining. One of the slides showed a capsule round the cocci, but some observers believed that such capsules did not exist.—Professor ARTHUR H. WHITE said that with regard to the cocci which exhibited capsules he had found the same in some of the organisms which he had got from certain cases this year. Weichselbaum and his school denied absolutely the existence of a round capsule in his cocci, but Jäger, who had considerable experience, stated that capsules were frequently seen. Between the supporters of the two there was considerable difference of opinion, both on that point and also as to whether the organisms were always Gram negative. The former school said that those organisms which were Gram positive were not the specific organisms. He mentioned the fact that sub-cultures of an apparently pure non-Gram staining organism became Gram-staining as showing that the question of staining was not yet settled.—Dr. CHRISTOPHER GUNN said that he had seen the child in the hospital. He was inclined to think that she had been ill for a longer period than the parents made out and that the choking was probably some defect of swallowing. About one and a half hours before death there were five or six fairly typical spots on her limbs. After death the body was almost covered with them.

HUNTERIAN SOCIETY.—A meeting of this society was held at Poplar Hospital on March 27th, Mr. John Poland, the President, being in the chair.—Mr. T. H. Openshaw showed the following cases: 1. A boy, aged 18 years, who had old Tuberculous Disease of the Knee-joint resulting in nine inches' shortening of the leg. 2. A little girl with Double Congenital Dislocation of the Hip successfully treated by Lorenz's method. The reposition was functionally perfect on both sides and anatomically perfect on one side. Mr. Openshaw said that by this method, out of 20 cases, six perfect results, nine functionally but not anatomically perfect results, and five cases in which relapse occurred might be expected. 3. A case of Rheumatic Ankylosis. The knees, ankles, and hips were ankylosed and for five years the patient did not walk at all. Now, with HESSING's apparatus with elastic traction, he could walk fairly well. 4. A Characteristic Groove on the Tibia. Mr. Openshaw considered that such cases were due to intra-uterine fracture.

5. An infant with Congenital Shortening of one Femur and Absence of Fibula. 6. A girl with Scoliosis and Rigidity of the Cervical Spine, possibly of rheumatic origin. 7. A child with Congenital Absence of the Left Tibia and Partial Absence of the Right Tibia, probably the result of intra-uterine fracture. 8. Ankylosis of Both Hips and Knees due to Gonorrhoeal Arthritis. The patient was able to walk with splints fitted with elastic traction.—Mr. Hugh M. Rigby showed the following cases: 1. A boy with Both Forearms fixed in a position of Pronation. The head of the radius on each side was displaced and there was ankylosis of both radio-ulnar joints. 2. A woman, aged 37 years, who had suffered from ascites in childhood. A few months ago her abdomen was opened in another hospital and fluid was removed. She was admitted into Poplar Hospital under the care of Dr. Theodora Thompson with ascites and intestinal obstruction. Mr. Rigby opened the abdomen and found great distension of the small intestine. There was gradual narrowing of the lower end of the ileum and the caecum and ascending colon were like those of a child, evidently a congenital condition. The patient made a good recovery after an ileo-sigmoid lateral anastomosis. 3. A boy from whose Ureter a Stone had been removed by a para-sacral incision. Mr. Rigby considered that this incision was indicated when a stone was impacted within two inches of the bladder, the operation by this method being easier and affording better drainage than the usual method.—Dr. H. Theodore Thompson showed the following cases: 1. A woman with a To-and-fro Aortic Murmur, Syncopal Attacks, and Tabes Dorsalis. He considered that she had syphilitic aortitis. 2. A man with an Abscess of the Lung treated by administration of creosote internally up to half-drachm doses and inhalation of creosote and iodine. He had gained 18½ pounds in weight in three months and was practically well. 3. A typical case of Disseminated Sclerosis.

GLASGOW OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.—A meeting of this society was held on March 27th, Dr. E. H. Lawrence Oliphant, the President, being in the chair.—Dr. Kelly showed a Ruptured Tubal Pregnancy, for which an operation was performed 24 hours after the onset of the symptoms.—Dr. J. M. Munro Kerr showed a Large Multilocular Ovarian Cyst removed from a patient, aged 24 years.—Dr. A. N. McLellan showed a Large Thin-walled Hydrosalpinx.—Dr. John Lindsay described two specimens of Malformation of the Fœtus.—Dr. J. Nigel Stark read notes on a case of a Fibroid of the Cervix Uteri, weighing 17 pounds and measuring 34 inches in circumference and 27 inches from side to side. It was removed by abdominal section and the operation was rendered somewhat difficult owing to the size of the tumour and to adhesions with the omentum and bowel. The body of the uterus could be seen perched upon it in front, freely moveable and not implicated in its mass. The tumour was subperitoneal in origin and grew from the posterior median part of the cervix; there was no pedicle to be found. The patient was 40 years of age and had had four children. She made a good recovery.—Dr. Munro Kerr said that in most cases of cervical fibroids the tumour could be shelled out of its bed and the uterus left intact. He had removed a tumour weighing 14 pounds and had fixed the uterus to the anterior abdominal wall, the patient subsequently menstruating.—Dr. Russell read notes on several cases of Pruritus Vulvæ which he classified under two headings—namely, those cases due to local conditions and those due to general conditions. The treatment was often unsatisfactory, local applications of heat and ointments being used. When the patient's health was suffering the parts ought to be excised. The danger of subsequent malignant disease occurring had to be kept in view in the treatment of these cases of pruritus.—Dr. Russell and Dr. J. Edgar communicated notes on several cases of Eranosis Vulvæ.

ÆSCULAPIAN SOCIETY.—A meeting of this society was held on April 5th, Dr. J. B. T. Conner, the President, being in the chair.—Mr. Elmore W. Brawerton demonstrated the following eye cases:—1. So called "Embolus" of Arteria Centralis Retinæ in a woman, aged 54 years, who one year ago developed sudden total loss of sight in the right eye while recovering from right hemiplegia. There was now well-marked optic atrophy, the disc was blanched, and the arteries appeared as white threads. The so-called "embolism" was probably an endarteritis with subsequent thrombosis and was seldom found in association with endocarditis,

forms without symptoms of suppuration, appendicitis with suppuration, appendicitis with perforation and followed by general peritonitis, and the fulminating or septic appendicitis. Dr. Dreschfeld discussed the various symptoms corresponding to the several forms of acute appendicitis, each one of which might be absent, though in most cases the pulse, the fever (remittent with or without rigors), the muscular rigidity with the presence of an intumescence either in the right iliac region or the pelvis (rectal examination should never be neglected), and leucocytosis showed the presence of pus. The diffuse and general peritonitis and the fulminating type were recognised more by the aspect and general conditions of the patient than by the local symptoms. Dr. Dreschfeld briefly spoke of the complications, such as venous thrombosis, pyelophlebitis, subphrenic abscess, liver abscess, empyema, meningitis, perinephritic abscess, &c., which might occur when the acute symptoms had subsided, and then spoke of the differential diagnosis. Primary typhlitis was rare, but did occur, as shown by post-mortem examination, where the appendix was found healthy and ulcers were found in the cæcum; it could not clinically be distinguished from appendicitis. Stagnation of faeces in the cæcum (stercoral typhlitis) occurred chiefly in old people and gave rise to no pyrexia and often very little pain in the ileo-cæcal region, and faecal masses were often detected in other parts of the large intestine. Tuberculous appendicitis generally ran a chronic course; in children, however, it might set in more or less acutely. In children intussusception and acetonaemia brought on by errors of diet might give rise to symptoms simulating appendicitis but their recognition was not difficult. Mucous colitis, intestinal spasms, enteralgia, and the appendicular neurasthenia or hypochondriasis were chronic non-febrile affections. Of other affections which might simulate acute appendicitis they had to consider typhoid fever, which during the first few days might simulate appendicitis at a time when Widal's reaction could not be made use of, but the cultivation of the typhoid bacillus from the blood on a medium containing bile was possible early. Appendicitis might occur during the course of typhoid fever and be due to typhoid ulcers either during the third week or during convalescence or the fever might rouse a latent appendicitis into activity. Cholecystitis, especially if there were adhesions and the gall-bladder was dragged down, might simulate appendicitis and in females affections of the ovaries gave rise to symptoms difficult to distinguish from appendicitis; moveable kidney and hydronephrosis should also be mentioned as closely resembling in their symptoms acute appendicitis; also hæmorrhagic pancreatitis. The perforation of a gastric or duodenal ulcer or of a pyosalpinx causing perforative peritonitis was often only to be recognised by the history previous to the perforation. As croupous pneumonia at its onset had sometimes been mistaken for appendicitis it was well to examine the chest repeatedly if there be any suspicion of a pneumonic affection. As regards medicinal treatment, Dr. Dreschfeld only drew attention to the points now well recognised. The important question in which cases and when to operate Dr. Dreschfeld left his surgical colleagues to discuss, and he would only remark that from his own experience he was in favour of an early operation and that he remembered no case in which he regretted having advised operation, whilst in some cases an operation earlier might have prevented some of the most serious complications.

Mr. F. A. SOUTHAM made some remarks on the advisability of early surgical interference in acute appendicitis and mentioned details of a number of cases which illustrated the good results of the so-called "early" operation (viz., within the first 48 hours), as compared with those which attended operation at a later period in the course of an attack. As regards the indications for early operation, attention was called to the fact that whereas in the initial stage the pulse-rate and temperature bore no constant relation to the severity of the attack, painful rigidity of the abdominal wall most marked over the region of the appendix, with absence of abdominal respiration, the breathing being mainly or entirely thoracic, were symptoms usually pointing to the onset or the presence of the destructive form of appendicitis, and indicative either of perforation or of gangrenous changes taking place in its walls. The chief advantages of the "early" operation were that the appendix could be removed before suppuration had taken place, and if it had not perforated or become gangrenous the operation was an aseptic one. If suppuration had taken place, even though not encysted or surrounded by a barrier of lymph, in the early stage the pus would usually be limited to the region of the appendix; in these

circumstances its evacuation together with the removal of the appendix, if followed by free drainage, generally checked the spread of the suppuration, which otherwise so often tended to become general.

Mr. A. H. BURGESS thought that too much stress had been laid on the difficulties of diagnosis of acute appendicitis and considered that of all the acute diseases to which the human abdomen was liable acute appendicitis was the least difficult to diagnose. Its symptoms were of a definite character and, as had been shown by Murphy and other surgeons, followed one another in a characteristic order—viz.: (1) pain, felt at first around the umbilicus, later over the appendix; (2) nausea, which in many cases, but not in all, proceeded to vomiting; (3) localised tenderness, most marked over the appendix; (4) rigidity of the overlying abdominal muscles of the "involuntary type"; and (5) rise of temperature and pulse. The importance of a rectal examination in every suspected case was strongly insisted upon, as was also the avoidance of morphine until the decision for or against operation had been made. Attention was drawn to the deceptive improvement in the symptoms which not infrequently manifested itself at the time when the appendix became gangrenous or perforated, due to a temporary cessation or diminution of toxin-absorption—an improvement which had been frequently overlooked and had led to fatal delay in advising operative treatment. The advantages of early operation, while the infection was still limited to the appendix, were enumerated, and the chief objections that had been raised to its universal adoption were considered. Having regard to (1) the minimum of risk attending removal of the appendix while the infection was limited to it; (2) the impossibility of foretelling whether the infection would remain so limited; (3) the greatly increased risk of operations carried out after extension of the infection to the peritoneum; and (4) the many disadvantages (apart from risks) which attended operations in the "abscess" stage (prolonged convalescence, weak abdominal scar, numerous adhesions, and appendix often left behind), Mr. Burgess advocated removal of the appendix as soon as a definite diagnosis of acute appendicitis had been made, believing that only in this way would the mortality of appendicitis be reduced to a minimum.

Mr. J. E. PLATT agreed with the remarks of previous speakers as to the necessity for early operation in acute appendicitis and expressed the opinion that at no distant date operation would be regarded as just as urgently required in these cases as in cases of strangulated hernia or ruptured gastric ulcer.

Mr. E. STANMORE BISHOP thought that most surgeons would agree as to the advisability of an operation during the first 48 hours, if that could be obtained, but it was not always possible, first through doubt as to the diagnosis, and secondly through refusal on the part of the patient to submit. The main difficulty, however, was not then, but in the period immediately after—that of the intermediate operation as it was called. It was only necessary to look at the second of Mr. Southam's tables to recognise the great mortality of which attended operations during that period, whereas if it were in any way possible to wait until a quiescent period the mortality was nil. His own experience tallied precisely with that. Moreover, they did not always get these cases during the first attack. Many patients had a previous history of several more or less mild recurrences. If such a patient came during the early period of one of these secondary attacks, was it wise to operate? He thought it was infinitely preferable to wait if that were possible, since such appendices were frequently buried beneath adhesions or behind the cæcum, needing long and sometimes tedious dissection to enucleate them, whilst the risk of setting free small collections of virulent pus was great. He believed that no hard and fast rule was possible. Each case must be judged on its own merits.

Dr. J. E. HELM, Dr. A. MACDOUGALL, and Mr. G. A. WRIGHT also took part in the discussion.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF PATHOLOGY.

Exhibition of Specimens.—*Sacro-coccygeal Tumour.*—*Cerebro-spinal Meningitis.*

A MEETING of this section was held on March 15th, Dr. W. R. DAWSON being in the chair. Dr. W. BOXWELL exhibited a Cerebellar Abscess taken

of the problems of health and disease with the biological problems of evolution, heredity, and variation, and since the publication of his work, "The Present Evolution of Man," the discovery of Mendel's researches has shed a fresh light on many puzzling questions connected with heredity. The results thus obtained within the past five years are of such practical value that some handbook is called for which presents to the public in small compass a summary of this recent progress.

With the reservations noted below Mr. Lock's volume supplies this want. As the preface states: "So far-reaching are the results already arrived at both in their scientific interest and in their probable influence upon human affairs, that it seemed desirable to give an immediate account of these and of kindred lines of recent study." In the first two chapters a brief summary is given of the various theories regarding the origin of species—the Lamarckian, Darwinian, and the mutation theories of Hugo de Vries—and also of the proofs of inorganic and organic evolution. Natural selection is next discussed and the chief arguments in favour of and against the inheritance of acquired characters are considered. One chapter deals with the remarkable results obtained by the methods of biometry introduced by Sir Francis Galton and now carried on so ably by Professor Karl Pearson. Another chapter is devoted to an exposition of the mutation theory, and the concluding third of the book is occupied by a description of Mendel's law, some of the intricate problems it sets or explains, and illustrations of its practical results. Readers of the discussions in our columns in 1899 and in 1903¹ are aware of the confusion of thought existing even in scientific circles as to the transmission of acquired characters. It behoves all medical men who desire to study heredity to try to understand very clearly this intricate problem; the attitude assumed by the medical profession towards this question will in the near future be of extreme importance to the welfare of the community. Most of the evidence to-day available points to the non-transmission of acquired characters; examples apparently pointing to the opposite conclusion are usually due to the difficulty of distinguishing between the inborn variations and the variations acquired during the lifetime of the individual when several successive generations are exposed to identical environmental conditions. Before the researches of de Vries and the recent discovery of Mendel's work (which was carried out at the same time as that of Darwin and then lost to the world for 40 years) Mr. Lock points out that the methods of plant and animal breeders depended upon guess-work or practical experience, but, he adds, "we are now within sight of the day when a complete system of precise scientific methods will have been elaborated. The time required for the development and application of these methods must chiefly depend upon the apathy or enterprise of those in whose hands rests the means of subsidising this kind of work, for without proper resources the progress of any such study must of necessity be slower than it would be if properly equipped establishments were at the disposal of duly trained experimenters receiving an adequate remuneration." With these words we cordially agree. The inadequate endowment of scientific research in almost every department in this country is matter for grave apprehension as to our future progress. As a nation we "muddle through" by experience after many blunders, and valuable time, energy, and money are wasted irretrievably where foresight gained by science would have yielded quicker and more profitable gains. Mr. Lock proves his point by his examples of the rust-free and other desired strains of wheat which have been obtained by the application of Mendel's

laws to the cultivation of wheat. Medical men will be interested to learn that Mr. W. Bateson of Cambridge from his study of the pedigrees of animals believes it is highly probable that certain congenital diseases in man are inherited in accordance with Mendel's law.

Towards the end of his book the author states that "the nearly historical order in which the subject-matter has been presented has inevitably rendered the treatment a little disjointed." We regret to have to confirm this statement. This historical survey has, moreover, rendered the arguments difficult to follow, and the constant references to counter-arguments in future or previous chapters break the line of the reader's thought and distract the attention. The subject to be condensed into 290 odd pages is so complex, so packed with facts, that only the most salient features should have been selected, and these should have been presented with concise definitions, uninvolved, methodical arguments and a straightforward style, such as is adopted by writers of students' text-books. To understand Mr. Lock's chapters on Mendelism the student would require to refer to Mr. R. C. Punnett's admirably clear little book on that subject. Mr. Lock is, in fact, hampered by too much knowledge, and his somewhat laboured style of writing will, we fear, prevent the volume receiving the welcome and wide reception from the general public which its subject matter so greatly deserves. We regret exceedingly to find these faults in a book so conscientious and thorough.

Midwifery for Nurses. By H. RUSSELL ANDREWS, M.D., B.S. Lond., M.R.O.P. Lond., Assistant Obstetric Physician, London Hospital. With illustrations. London: Edward Arnold. 1906. Pp. 308. Price 4s. 6d. net.

THIS little work has been written by Dr. Andrews for the use of pupil midwives. A perusal of it gives a good idea of the amount of knowledge a midwife is required to have at the present day, and the amount certainly is considerable. It is fairly easy for the writer of such a work, now that he has the regulations of the Central Midwives Board to guide him, to refrain from going into details which are not necessary. It is, however, certainly surprising to find the amount of detail which is given in a book of this kind, and while we feel that the modern midwife at any rate should be well trained yet we wonder whether the ordinary type of pupil midwife is really capable of learning and retaining such an amount of information. Dr. Andrews has certainly done his work well, his book is clearly written and well illustrated, and if we find certain statements to which we may take exception, our criticism does not mean that we do not approve of the general style of the book, which is excellent. We regret to see that the old-fashioned and unsatisfactory method of treating the nipples with eau de Cologne or some similar astringent is still recommended; we would advise as a much better plan the use of lanoline or any ordinary antiseptic ointment. On p. 43 is the statement that if a woman continues to suckle her child when pregnant uterine contraction may be set up and abortion induced. We wonder what authority the author has for this statement. Cases of lordosis so marked as to simulate pregnancy are so uncommon that it seems hardly worth mentioning them in a book intended for midwives. Personally, in a very considerable experience we have never seen such a case. The account of abdominal palpation is, as it should be in a book of this description, especially good. In the instructions for passing a catheter the nurse is told if there is any difficulty in finding the urethra to place the patient on her back. As a matter of fact such difficulty is much more likely to be met with in this position than when the patient is on her side, the position we suppose Dr. Andrews would recommend, although no instructions are given upon this

¹ THE LANCET, October and November, 1899, and July, August, September, and October, 1903.

but often occurred in cases of hemiplegia either before or after the attack. 2. A girl, aged 20 years, whose right eye showed absence of the Arteria Centralis Retinæ, probably due to a congenital abnormality and a reversal to the type met with in the carnivora, especially the wolf. 3. A girl, aged nine years, with Spurious Optic Neuritis which had existed for three years without affecting the vision. The condition was that of congenital swelling of the disc due to a form of opaque nerve fibres. 4. Pseudo-Glioma in a baby, aged ten months, showing shrunken right eye, small anterior chamber with retracted angle, old iritis, and greatly decreased tension—signs which all pointed away from true glioma. The usual history was that a child had had convulsions, was extremely ill generally, had general congestion of the eye, and had no fundus reflex. Pseudo-glioma was probably due to a septicæmia, so was really a form of septic infarct into the vitreous, which got filled with purulent, but not very virulent, material. The condition subsided and left a dense cicatricial mass in the vitreous. The treatment was to leave the eye alone.

Reviews and Notices of Books.

Anæsthetics: their Uses and Administration. By DUDLEY W. BUXTON, M.D. Lond., M.R.O.P. Lond. Fourth edition. (Lewis's Practical Series.) London: H. K. Lewis. 1907. Pp. 415. Crown 8vo. Price 7s. 6d.

A HANDBOOK which has so well justified its existence as to have reached a fourth edition needs little in the way of commendatory criticism, but we deal at some length with the latest issue of Dr. Dudley Buxton's excellent and well-known volume because there are contained in it several important new features to which attention may profitably be drawn, while a word of praise must be given to the complete manner in which the writer has covered all the wide field comprised in the practical side of anæsthesia. A valuable chapter deals with the use of anæsthetics in obstetric practice. This is an aspect of the matter to which the text-books commonly pay too little attention and a precise knowledge of which is of the greatest service to the general practitioner. It is not merely that a patient's comfort is so materially enhanced by the presence of some degree of anæsthesia in labour, but, further, the safety and the proper progress of a confinement are directly aided by the employment of chloroform in the various stages of the birth. Dr. Buxton points out in a series of epitomised rules the degree of anæsthesia to be reached in the various circumstances of normal and abnormal cases of confinement, and we consider his directions in this matter to be one of the most valuable portions of the volume. The old objections to administering chloroform during labour are nowadays widely abandoned, but there are still many whose fears are justified in the absence of exact knowledge in the matter. Better no chloroform in many cases than chloroform wrongly used. To all who may be swayed by such a feeling we most warmly recommend a perusal of this chapter on the matter in Dr. Buxton's little book.

The present edition has been brought up to date by considerable additions. The new matter relates mainly to dosimetric apparatus for the administration of chloroform, to ethyl chloride and allied drugs, and to spinal anæsthesia. The last is a topic which is often omitted from books upon anæsthetics and we are glad to see it included in a volume of this nature, which is designed to give to the student and the practitioner a good general survey of the entire subject of anæsthesia. With the large amount of literature that has accumulated quite recently upon matters germane to anæsthetics, such as, for instance, shock and the gases of the blood, Dr. Buxton has wisely not attempted to cope. He prefers, generally speaking, to lay down the practical rules deduced

from the scientific work of physiologists rather than to give an account of the work itself. The author finds ethyl chloride not good for alcoholic cases, which opinion is in interesting contrast with that of some other anæsthetists who in this very class of case select it as against nitrous oxide. He does not consider posture as of much importance in the case of this drug except where the aged are concerned.

With regard to the administration of chloroform Dr. Buxton is a warm supporter of Professor Vernon Harcourt's apparatus, of which he gives an excellent account and from which he has obtained highly satisfactory results. In the chapter upon Spinal Anæsthesia an accurate account is given of the exact method to be employed, with a couple of figures, supplied by Dr. J. Mackenzie Davidson, to show the position of the needle. The author prefers stovaine to other drugs for spinal anæsthesia when this method is employed, but he thinks that at present its dangers are greater than those of chloroform in skilled hands. He enumerates a formidable list of after-effects that may be evoked. A short account of regional anæsthesia is also given, as well as a comprehensive description of local analgesics. The volume concludes with an interesting chapter upon the Medico-legal Aspects of the Administration of Anæsthetics. Here the cases are discussed wherein persons have alleged that they were chloroformed against their will and with astounding rapidity, and the attitude is considered of the person who is conscious but powerless to resist. Discussing the possibility of anæsthetising people during sleep the author relates the experience of Dolbeau who in one series of nine persons anæsthetised six without awakening them.

In a chapter upon the accidents of anæsthesia and how to treat them Dr. Buxton wisely alludes first to the precautions which must be taken to avoid the occurrence of accident. It is in the prevention of accident far more than in its treatment that an anæsthetist's skill and experience are commonly exhibited, and it may be laid down as an axiom that the more accomplished the administrator the less often will he require skill in the treatment of dangerous conditions. Dr. Buxton, we are glad to see, lays stress upon the ill effects of an enema given shortly before operation; not uncommonly severe shock is caused by this proceeding. Even in the case of rectal operations there should be at least one hour's interval between the administration of the enema and the commencement of the inhalation of an anæsthetic. Dr. Buxton has nothing to say in favour of the use of alcohol before the administration of an anæsthetic.

Recent Progress in the Study of Variation, Heredity, and Evolution. By ROBERT HEATH LOCK, M.A., Fellow of Gonville and Caius College, Cambridge. London: John Murray. Pp. 299. Price 7s. 6d. net.

A COMPREHENSION of the laws of heredity is so important for those who work for the improved physique of the human race that it is matter for regret that so little is known about the subject with any certainty. Medicine has been so fully occupied by the study of disease in the individual, and the study of sanitary and other sciences concerned with its prevention, that the attention of the medical profession has not until quite recently been directed to the power of heredity and environment on the physical and mental nature of man. When it is remembered that Darwin's "Origin of Species" was only published in 1859, and that for many years after that event the problems Darwin had given to the world had of necessity to be confirmed and worked out in detail by those engaged in the study of botany and zoology, this indictment is scarcely so grave as it would at first sight appear. Dr. Archdall Reid has pointed out in a manner that challenged and held the interest of both the medical and scientific public the vital connexion

THE LANCET.

LONDON: SATURDAY, APRIL 13, 1907.

Thomas Henry Wakley, F.R.C.S. Eng. In Memoriam.

THE personal sorrow which those who are immediately connected with THE LANCET are feeling at the death of their venerable senior editor will appeal to the sympathy of our readers all the world over. Under the dispensing will of Providence the directing hand of the oldest of our councillors is for ever at rest. We do not intend, either here, or in the more detailed biographical notice which will be found in another column, to speak at any great length of him whose long, active, and useful career has just been closed by death, but we consider it appropriate to say a few words respecting the late senior editor of THE LANCET beyond what is merely biographical.

It is natural that at this moment we should look back some 20 years when the death of JAMES GOODCHILD WAKLEY, THOMAS WAKLEY's youngest brother but predecessor in our editorial chair, occurred; and it is interesting to see how extremely appropriate the words then written under THOMAS WAKLEY's direction concerning his brother are applicable to himself. The brothers had great community of personal characteristics and temperament, although their preliminary education differed widely. The life-work of each as far as it was connected with THE LANCET was very similar, the parallel having originated in the fact that each regarded his position as editor of THE LANCET as a heritage from the father who founded the paper, and each conducted the paper with the same broad objects in view. "The unsparing rod wielded by his father against all enemies, and the sometimes too great admiration extended by his father to attached friends—extremes which are so commonly marked in men of the most powerful order—were extremes unknown to him," was written of JAMES WAKLEY, and is absolutely applicable to THOMAS WAKLEY. The following sentence is equally true in description of either: "He did not write much himself, but he was skilful and keen in discovering men who could write, and what they could write; and he read every line that was written by his staff in which there was anything controversial with the most scrupulous nicety and supervision. He was bold in exposing

evils of a general or public character; hearty in helping forward every public advancement; zealous to make THE LANCET the first chronicler of any new and promising progress in the science and art of medicine; and especially anxious to make it useful in works which were of a sound philanthropical and beneficent nature." It would not be possible to describe the journalistic attitude of him whose death we are now mourning more accurately.

No one occupying an important public post and exerting through it a daily living influence on the profession of medicine was ever more retiring from professional social life than the late THOMAS WAKLEY. On succeeding to the editorial chair he seems to have felt that the only way to preserve the unbiased judgment necessary for a right apprehension of the pros and cons of professional questions was to be as far as possible removed from personal conflicts himself. His father, the founder of THE LANCET, was essentially a public man; as politician, journalist, and public official he was welcome in all circles and enjoyed to the full the variety of a far-extending society, despite the manifold duties appertaining to his busy and complex career. THOMAS WAKLEY, the son, was totally different. His aim was ever to keep in the background, to subordinate himself to his public duty, as he conceived it, and to allow no extraneous influence of any sort to warp his judgment or deflect his just sympathies. He believed that in this way he could best serve his generation by means of THE LANCET, for as his father and his brother loved their journal, so did THOMAS WAKLEY love it. He lived for it and for the promotion of the causes which it advocated, and in a curiously exact way the journal walked hand in hand with him throughout his career. He was born almost contemporaneously with the first issue of the paper; while he was passing through the stress and excitements of boyhood the passionate proceedings of THE LANCET in the heyday of its youth were attracting the notice of the medical and legal professions. Early middle age found THOMAS WAKLEY an established success as a consulting surgeon, while the position of THE LANCET was at length secure, its wild oats having been sown; by the time that it fell to his lot to direct our councils he was well advanced in life, of set habits and opinions, while THE LANCET had a long career of useful work behind it and a definite place in the professional counsels of the country. The feeling that THE LANCET had grown up with him was always strong upon him, and increased his sense of responsibility for its conduct. He gave all his energies to the discharge of the task, and allowed no private influences to interfere between him and his sense of justice—and whatever eulogy we might add we could not draw a better picture of the man and his grasp of his duties.

point. There can be no question as to the marked superiority of the lateral position in passing a catheter. We regret to see that our old and tried friend tincture of iodine is said on p. 67 to be a weak antiseptic; that it is objectionable is true but that it is weak is wholly inaccurate, as any chemist will tell the author. In the section on the mechanism of labour we notice that the old erroneous teaching about flexion of the head is perpetuated; no doubt this is not a matter of much importance in a text-book for midwives, but still accuracy is a good thing, and it has long ago been shown that at the commencement of a normal labour the head is already completely flexed. In the management of cases of unreduced occipito-posterior presentations instructions are given to flex the head by pressure on the forehead, but the necessary addendum that such pressure will only be of any value if applied during a pain is not given. We can hardly believe that even a modern midwife should be taught to rotate the head manually with the whole hand in the vagina, but so it appears they are taught, at any rate by the author. The statement that where the diagnosis is difficult the nurse should feel for an ear and that the lobe will point towards the occiput is inaccurate and misleading. Anatomically, Dr. Andrews should remember that the lobe of the ear is the lobule and as a matter of practice the groove between the pinna and the skull is a much more easily appreciated and trustworthy guide than the direction of the pinna as a whole, which we suppose is what is meant. The section on the artificial feeding of infants is good and clear. We think, however, that all milk given to a baby should, at any rate, be scalded if it is not sterilised. We presume that sterilised is meant when the statement is made that boiled milk gives rise to scurvy. This is certainly not true of scalded milk even if it be true of sterilised milk. No doubt cases of scurvy do occur from time to time but they are infinitely rare and the risk is so small that we certainly think it is almost negligible. It is far better for the ordinary baby to run the very slight risk of scurvy than to drink unboiled milk. Pasteurisation, in our opinion, is quite unfeasible for the ordinary poor mother, while any woman, however careless, can scald her baby's food. On the whole there are a good many little points of detail in this text-book on which we differ from the author, but none the less the book is a fair example of its kind, although the arrangement of the chapters is rather wanting in method. No doubt many of these faults will be corrected in any future edition.

LIBRARY TABLE.

Aids to Dental Surgery. By ARTHUR S. UNDERWOOD, M.R.C.S. Eng., L.D.S., and DOUGLAS P. GABELL, M.R.C.S. Eng., L.R.C.P. Lond., L.D.S. London: Baillière, Tindall, and Cox. 1907. Pp. 126. Price 2s. 6d.—This second edition is really the work of Mr. Gabell but he has had the advantage of Mr. Underwood's supervision. Mr. Underwood has read all the proofs and given valuable aid. The arrangement of the matter has been considerably altered to harmonise with more modern ideas and two new chapters on bacteriology and the hygiene of the mouth have been introduced. The whole book is brought up to date. The object of the authors is to treat most fully those matters the discussion of which comes obviously within the range of the theoretical portion of examinations. That portion of dental surgery which is purely manipulative is entirely omitted. The book is what it pretends to be, an "aid" to dental surgery, and it will, we think, be appreciated by the large body of dental students. The book is well arranged and well written.

The Municipal Year Book of the United Kingdom for 1907. Edited by ROBERT DONALD. London: Edward Lloyd, Limited. 1907. Pp. 684. Price 3s. 6d. net.—This is a compilation containing a mass of information, among which every ratepayer will find something to interest or to distress

him as the case may be. The complex methods of modern life strike the reader as more wearing than ever when he sees them set down, as in this book, in masses of figures and tables.

The Medical Annual. A Year-book of Treatment and Practitioner's Index. 1907. Twenty-fifth year. London: Simpkin, Marshall, Hamilton, Kent, and Co. Bristol; John Wright and Co. Pp. 863. Price 7s. 6d. net.—We have, in noticing previous issues of this annual, almost exhausted the language of eulogy, so that little more need be said now than that the present edition is worthy of its predecessors. It is the oldest of the annuals and the accumulated experience of many years has enabled the editors to bring the work to a very high degree of perfection. The contributors are all known to be experts in those branches of the medical sciences with which they deal and much judgment is shown in the selection of the material dealt with and in the comments which are made. Coloured plates have always formed a great feature of the annual and the increased circulation has enabled the publishers to be very generous in the provision of coloured illustrations. This year they include several relating to cancer and two picturing *spirochæta pallida*. For any busy practitioner who wishes to keep himself up to date no better volume can be found.

JOURNALS AND MAGAZINES.

Folia Therapeutica: a Periodical Journal relating to Modern Therapeutics and Pharmacology for Medical Practitioners. Edited by J. SNOWMAN, M.D. Brux., M.R.C.P. Lond. London: John Bale, Sons, and Danielsson. January, 1907. Pp. 31. Price 1s.—This forms the first number of a new medical publication which it is proposed to publish quarterly. The idea of the proprietors is to devote the journal to publications on the progress of modern therapeutics and pharmacology, and to present in a brief and concise manner the methods of treatment and preparations which can be safely recommended for use and which constitute a real advance in therapeutics. The evidence given for the trustworthiness of any treatment or drug will consist in the authority of the authors by whom or under whose supervision the investigations have been made. It is intended that the journal shall contain original contributions from British and continental authorities on therapeutics and pharmacology; reprints, translations, and abstracts from British and continental medical journals relating to therapeutics, and reports from leading clinics and hospitals. This first number faithfully carries out these intentions. Professor O. A. Ewald (Berlin) contributes an interesting article on the Treatment of Gastric Ulcer and its Complications. He dwells particularly on the course of treatment to be pursued after recent hæmatemesis and considers rest the most important point in the measures to be adopted. He speaks favourably of the use of gelatin in combination with fat in the treatment of those cases of gastric ulcer in which hæmorrhage has taken place. Dr. Adolf Baginsky (Berlin) writes on the Subcutaneous Injection of Physiological Saline Solution in the Treatment of Diseases of Children. Such injections have produced favourable results in his hands in cases of severe summer diarrhoea of children. Amongst other contributions to this number are the following: On Yeast Therapy, by Professor E. Roos; the Scope of Digitalis, with Special Reference to Chronic Kidney Disease, by Dr. N. Tirard; Some Observations on the Therapeutics of Chronic Heart Disease, by Dr. F. J. Wethered; and Uterine Hæmorrhage treated by Stypol, by Dr. M. Handfield-Jones. There are several abstracts from articles on therapeutics culled from various sources, and also a list of contributions to medical literature which have recently appeared. The journal is well printed on good paper.

observed, such as ptomaine poisoning and septicæmia in association with erysipelas, acute periostitis, and extensive burns, and he found in eight out of the 13 that early changes occurred in the Betz cells of the cortex, though no changes were observed in the cells of the medulla and cord. This greater susceptibility of the more highly evolved cells to toxic influences is noteworthy and of interest, as Dr. BUZZARD points out, in connexion with the easily produced exhaustion after voluntary effort familiar in association with toxæmic states. In regard to changes observed in the nerve fibres in these cases the diffuse fatty myelin change was frequently observed, while the Wallerian type was observed only once and then of slight degree.

The second lecture was entirely devoted to a consideration of the disease usually known as infantile spinal paralysis, for which Dr. BUZZARD prefers the title of "acute poliomyelitis." The pathological histology and pathogenesis of the condition were carefully described and illustrated by the appearances observed in three fatal early cases. The most widespread and constant changes are congestion of the blood-vessels and an intense cellular infiltration of their walls, the veins and the capillaries showing the greatest degree of infiltration. These cells are for the most part mononuclear and their origin is still a matter of dispute, but they are probably chiefly derived from cells existing in the walls of the vessels; at any rate, there is no evidence of their neuroglial origin. Round-celled infiltration of similar character occurs in the meninges, especially over the lower part of the cord and on its anterior aspect. There are also masses of cells scattered more or less irregularly through the grey matter, particularly in the anterior horns but not confined to them; these masses Dr. BUZZARD regards as probably due to neuroglial proliferation and lymphocytic infiltration. The ganglion cells of the anterior horn, of Clarke's column and of the posterior horn all suffer in varying degrees, the general but not invariable rule being that those cells most closely involved in the inflammatory exudation show the most marked changes, these varying from early chromatolysis to a condition in which it is difficult to detect the outline of the cell. In discussing the pathogenesis of the disease in the light of his own observations and those of other writers Dr. BUZZARD rejects the old view that it is the result of a primary degeneration of the anterior horn cells with secondary changes in the interstitial tissues and also the so-called "vascular" theory—viz., that it is due to primary thrombosis of the vessels of the cord—and concludes that the process is inflammatory and is probably due to some micro-organism or its toxin, circulating in the blood (but possibly in the lymph). He further concludes that the same morbid process underlies some cases of encephalitis, both of the brain stem and the cerebrum, including probably many examples of infantile hemiplegia.

The third lecture was devoted to a study of acute ascending myelitis, of Landry's paralysis, and of acute toxic polyneuritis. The first of these is regarded as an acute infective disease, not of specific character, and produced by various micro-organisms. Evidence was offered in support of the view that this bacterial infection affects the lymphatic system of the spinal cord. In three cases of Landry's paralysis practically the only change observed

apart from diffuse myelin degeneration in the white matter of the cord and in the peripheral nerves was in the ganglion cells of the spinal cord, which showed early pericentral chromatolysis. From a study of the bacteriological and pathological observation so far on record this disease is to be regarded as "possibly a species of spinal lymphatic intoxication." The condition of acute toxic polyneuritis is one which offers some difficulty in diagnosis from Landry's paralysis. It is less often fatal, but in such cases the lesions have been found to be limited to the lower motor neuron, or to the lower motor and sensory neurons, and are probably parenchymatous degenerations of those structures produced by a toxæmia.

Death Certification and Amendment of the Coroners Acts.

WE referred recently¹ to the proposals set before the Lord Chancellor by a deputation from the London County Council and the Medico-Legal Society. It is of interest to consider somewhat closely the bearing of the proposed changes upon general medical practice in connexion with a more detailed account of the deputation (see p. 1034). One of the most important suggestions for amending the Coroners Acts is that which insists that the medical certificate shall show the fact of death as well as its cause and should vouch for the identity of the deceased. This means that the medical man who signs the certificate of death shall also visit the body after death, so as to be able to state not only that the death has occurred but that the body is that of the person named. In some cases this practice of identification may mean a long journey, and who is to pay for this? At present the death certificate is given by the medical attendant without charge, but it cannot be expected that he shall pay the compulsory visit of identification for nothing. Who is to pay for this visit, the friends of the deceased or the State? At the very low estimate of 1s. per inspection the sum would amount (it is calculated) to about £20,000 a year, whilst if the fee is made equal to that given for the compulsory notification of infectious disease the cost would be two and a half times as much, or a matter of £50,000 a year. Anyhow, the prospect of so large a sum of money being paid out of public funds might make the Government hesitate before proceeding with the measure, unless the usual attempt is made to secure gratuitous medical service.

The section providing that independent medical men should be appointed to assist the coroner in preliminary inquiries, in scrutinising the causes of death, and in making post-mortem examination is a very radical change, one that is chiefly if not solely necessitated by the preponderating number of purely legal coroners and by the imperfect qualifications of their subordinate officers. The dangerous habit of certain coroners of dispensing with medical evidence has been frequently commented on in our columns. Granted that the existing law requires alteration, there is no excuse for coroners breaking the law, while in many recorded instances the absence of medical evidence has been a direct menace to the public safety. In numberless cases it is the practitioner

¹ THE LANCET, March 30th, 1907, p. 900.

The Goulstonian Lectures.

THE widespread disturbances of function resulting from acute toxic or infective conditions of the nervous system are well known to clinical observers and have long been recognised by them, but the knowledge of the underlying anatomical or structural changes is of much more recent acquisition and is less generally current. Modern histological research on the normal structure of the central and peripheral nervous system has resulted in the discovery of methods which have proved fruitful subsequently when applied to the investigation of morbid conditions of those organs. The methods are in many cases complex and the results obtained by them have been in the past difficult to interpret; indeed, even at the present time there are differences of opinion as to how far the appearances observed are to be regarded as *ante mortem*, but the study of the *rationale* of these methods by histologists and neurologists has invested them with a real value and given them a definite significance. Dr. E. FARQUHAR BUZZARD is to be congratulated on having availed himself of the opportunity afforded him by the delivery of the Goulstonian lectures before the Royal College of Physicians of London to draw attention to these matters and to bring forward his own work on the subject. In these lectures, which have already appeared in our columns,¹ he has carefully analysed the pathological features of certain selected conditions of acute paralysis of widespread distribution, and presumably of toxic or infective origin, and in so doing has made a useful *résumé* of the main facts known in regard to the pathology of those diseases; while by his own observations he has brought forward valuable information regarding obscure points in connexion with them.

His first lecture was largely devoted to a general consideration of the effects upon the structures of the nervous system, especially those subserving motor functions, of various toxic agents, including some which apparently have a specific affinity for these structures and others for purposes of comparison or control of more general and widespread activity. The motor cells comprising the large pyramidal or "Betz" cells of the motor region of the cortex cerebri, the cells of the anterior horn of the spinal cord, of the motor cranial nerves, and of the nucleus ambiguus, all belonging to the so-called "stichochrome" class, have been studied by many observers in various abnormal states by the agency of the method of Nissl, which is that almost universally employed for the purpose. It depends upon the selective activities of certain basic aniline dyes and demonstrates that these cells present two separate substances—one basophile, called the chromatic substance, found in the nucleolus, the nuclear membrane, and in the form of certain masses in the protoplasm of the cell body and its dendrites, to which the name of Nissl bodies has been applied; the other substance is non-basophile and is therefore called achromatic. This substance is regarded by various observers as pervading the cell body and the axis-cylinder process in the form of a fine granular network, the meshes of which inclose the Nissl bodies. In the normal cell of the stichochrome class the general outline of the cell is polygonal with

concave borders between the bases of its processes, the nucleus is of rounded form and usually centrally placed, the nucleolus being in turn situated at its centre, while the Nissl bodies are usually arranged along pericentric lines—that is, lines more or less parallel with the borders of the cell. This method applied to the study of the cellular changes produced by various abnormal states or conditions has shown that those resulting from toxins are very similar to, if not indistinguishable from, those resulting from other influences, such as high temperatures, artificial anæmia, and great cellular activity; moreover, the so-called "axonal reaction"—that is, the alteration in the cell consequent on injury or degenerative conditions of its axis-cylinder process—closely resembles the changes induced primarily in the cell by toxic agents. The problems involved, therefore, in elucidating the effects of such agents are obviously complex and require careful unravelling.

In describing the acute toxic changes in these cells Dr. BUZZARD recognises three types: early forms in which the cell is little altered in shape, but in which the chromatin granules or Nissl bodies are breaking into fine particles especially around the nucleus or near the periphery of the cell, changes which are described as perinuclear and peripheral chromatolysis respectively. In another form of early change the cell is somewhat swollen and the whole cell body stains more deeply owing to the fragmentation of the chromatin particles and to the achromatic substance becoming more susceptible to the stain. In the second variety of change, referred to as the moderate type, the cell is round and swollen, the nucleus is no longer central, and there is complete, or almost complete, chromatolysis. In the third, or advanced, type the cell is globular in shape, of homogeneous or vitreous appearance, and the nucleus is either near the surface, or actually extruded from the protoplasm, while in another form of this type, the cell having retained something of its original shape, is, together with the nucleus, uniformly lustreless, the nucleolus alone being distinguishable. The general conclusions arrived at are that the histological appearances observed are not distinct from those obtained in other conditions and that no poison exerts a change which is recognisably different from that evoked by other poisons.

For the study of early changes in nerve fibres the Marchi method or the "Busch" modification of it is usually employed, and Dr. BUZZARD describes two different conditions as occurring in acute toxic states—the first practically indistinguishable from the well-known Wallerian degeneration but not necessarily secondary to changes in the corresponding cells; the second the appearance of numerous fine rounded drops of fat or rather of material stained by the Marchi process in the white fibres of the central nervous system or in the peripheral nerves. These droplets usually lie within the myelin sheath but are seldom large enough to occupy more than half of the transverse diameter of the fibre. This second form, which he has observed in toxic states of all kinds, Dr. BUZZARD regards as a fatty degeneration of the myelin sheath analogous to the fatty change found in other organs in toxic conditions. For purposes of comparison he has studied the condition of the nervous tissues and of the muscles in 13 cases of general toxæmia in which paralysis was not

¹ THE LANCET, March 16th (p. 706), 23rd (p. 785), and 30th, 1907 (p. 863).

authority and seldom do so. A good example of the advantage which may sometimes be gained by timely intimation to the medical officer of health of cases of this kind appears in the annual report for 1906 of Dr. G. Arbuckle Brown, the medical officer of health of Partick, who gives a detailed account of a case of tinned meat poisoning which occurred last year in that burgh in circumstances specially favourable for investigation. The incriminated tin was a large one and contained about four pounds of ox beef manufactured by a Chicago firm. It was opened by a Partick provision dealer who was in the habit of selling canned beef in small quantities, about a quarter of a pound at a time, to customers of the poorer class. The beef was turned out on to a plate provided with a cover, and portions of it were purchased on Saturday night, May 26th, or on the following Monday morning, by persons in five different households. Out of 19 persons constituting the five families as many as 12 were affected. In each family those who had not partaken of any of the suspected meat escaped, while those who partook of the meat, in some cases only in very small quantity, were attacked. The symptoms were mainly those of acute gastro-intestinal irritation. Within two or three hours, or less, of eating the meat the patients were attacked by severe abdominal pains, vomiting, and purging, together with, in some cases, severe prostration, collapse, and marked cyanosis. No fatal case occurred, although for a time the condition of some of the sufferers was very grave. Recovery was rapid and apparently complete after two or three days in nearly all the cases. A house cat which had been given some of the meat also suffered from acute intestinal irritation. Fortunately a portion of the suspected meat remained at the purveyor's shop and was available for examination. No trace of metallic poison could be detected in it. The observations recorded by Dr. Brown appeared to negative the assumption that the meat became poisonous as a result of bacterial action after the tin was opened. Having regard to the rapid onset of symptoms, to the absence of anything like an incubation period in any of the cases, and to the rapidity of recovery, it seemed that the poison must have been already present in the meat at the time of ingestion, and probably existed as a toxin of bacterial origin. The matter was put to further trial by testing the agglutinating action of the blood of eight of the patients on a stock culture of Gaertner's bacillus. In all cases a strong reaction (20 to 30 minutes with dilutions between 1 in 30 and 1 in 60) was obtained. Bacteriological examination of the meat did not reveal any evidence of the presence of living Gaertner's bacillus. It is known, however, that cultures of this bacillus may be killed by heat but yet remain poisonous in consequence of the endotoxin they contain, and Dr. Brown on review of the agglutination tests and of the whole investigation points to the strong probability that in this case the meat, before being tinned, was infected by the Gaertner bacillus and that at the time of heating and sterilisation endotoxins were set free from the destruction of the bacilli, thus giving rise to immediate symptoms of poisoning on ingestion.

A CASE OF POISONING BY NITROBENZENE.

In the *Boston Medical and Surgical Journal* of Feb. 14th Dr. John L. Ames records a case of poisoning by nitrobenzene. The patient, aged 47 years, drank from a bottle containing nitrobenzene thinking it to be sarsaparilla. It burned his throat and he immediately became ill. When taken into hospital he was cyanotic, the blue appearance of the skin and mucous membranes being very marked. The surface of the body was cold and the temperature was 97° F., the pulse was 130, weak and irregular, and the respiration was 30. The patient was semi-conscious and

there was marked prostration. The blood was chocolate-coloured and very thick and viscid. A pint was withdrawn, in a thick tarry condition, by venesection and was replaced by normal saline solution. Stimulants, liquids, and oxygen were administered freely. He responded well to the treatment and began to improve after 12 hours. After two or three days cyanosis disappeared and the blood became normal. Poisoning by nitrobenzene is rare; the symptoms are similar to those of acetanilid poisoning, only they are more intense. The condition of the blood is one of methæmoglobinæmia. In the case under notice the urine was negative except for an increase in the urophens.

THE SMELL OF PAINT.

THE smell of paint occasions distress to a good many people and the spring-cleaning season, when it involves the painting as well as the cleaning of the house, is dreaded, not on account merely of its interfering with the ordinary comforts and conveniences of the home, but because also in not a few cases a distinct disturbance of health is threatened. Persons who are sensitive to the vapours of paint, or, what is the same thing, to the turpentine and oils contained in the paint, are well advised to resign their home until the drying influence of the air has dissipated the volatile oils. Turpentine, even in the form of vapour diluted with air, undoubtedly affects the health of some persons, the disturbance manifesting itself in the shape of giddiness, headache, deficient appetite, and anæmia—a typical case is recorded this week. There were headache, vomiting, swelling of the tonsil, albuminuria, and a marked rise in the temperature apparently due to an exposure to the emanations of wet paint for nearly a fortnight. That such a case should now and then arise is not surprising when regard is paid to the toxic effects which turpentine vapour is capable of setting up. Turpentine, in short, is a poison and cats and rabbits are so susceptible to its action that if kept exposed to its vapour for some minutes, they exhibit marked toxic symptoms ending in death if they are not removed from the sphere of action of the vapour. Personal idiosyncrasy, however, is clearly an important factor, for many persons and probably the majority do not seem to be affected by turpentine vapour to any serious degree. A very sensible precaution during the painting season for those to take who are compelled to endure the nuisance is to leave bowls of water in the freshly painted rooms. Some, at any rate, of the paint emanations are thus absorbed, as will be seen by the oily film on the surface of the water so exposed. An even more powerful absorbent is fresh milk which reduces the smell of paint in a room in a remarkable way. The poisonous effects of paint emanations do not appear to be connected in any way with the lead contained in the paint, the colic of painters being due to the actual contact of the person with the substance of the paint.

THE BRITISH LEGATION AT TOKIO AND ITS MEDICAL OFFICER.

IN THE LANCET of Oct. 14th, 1905, p. 1119, we called attention to the fact that the medical officer to His Majesty's Legation at Tokio was not only a foreigner—namely, Dr. Wansch of German nationality—but a medical man who did not possess a qualification registrable in Great Britain or Ireland. We pointed out that although any unregistered person could practise medicine in the British Empire, provided that he did not imply that he was registered, yet that an unregistered practitioner could not hold certain appointments and could not sign certain necessary certificates. We alluded to some correspondence which had passed between Mr. Sidney Gerald Gomes, F.R.C.S. Edin., a British subject practising in Tokio, and Sir Claude Macdonald, H.B.M. Minister, Tokio, in

in attendance on the deceased who can alone complete the story. His place as a witness cannot be taken by an independent medical investigator who never saw the deceased in the flesh. Such a witness can only help the non-medical coroner to appreciate rightly the evidence of the practitioner. In the public interest the account of the cause of death, and if necessary of the result of the post-mortem examination, should be exact and true, and if, as the petitioners recommend, "the records of all such inquests should be public property," it would be well that they should be made by an independent and specially competent person. Medical practitioners, who not unfrequently suffer from the ignorance of the coroner as well as of the jury of the elements of medical science, would welcome the innovation. The cost of the independent medical assessors would, of course, be borne by the county, and the provision as to the number and the emoluments of these special referees would be made by grouping towns and country districts together. The proportion of uncertified to total deaths varies from 1.2 per cent. in London to 8.5 per cent. in North Wales, and to 42 per cent. in Inverness-shire—a proportion which caused great astonishment even to the Lord Chancellor. No doubt the large percentage of 42 is due, as was explained, to the scattered population, but whatever difficulty exists ought to be grappled with and remedied, for there can be no doubt that the possibility of burial without due certification and registration does actually exist.

The recommendation of the Medico-Legal Society put forward by the deputation—that there should be mortuaries with proper equipment for thorough investigation into the causes of death—is so manifestly sensible that there can only be surprise that at the present day it is necessary to call attention to such a want. Recent research in morbid anatomy and bacteriology has made it essential that the mortuary of the future must be properly equipped. Whilst agreeing with most of the recommendations and views placed before the Lord Chancellor in excellently plain terms we must again call attention to the difficulties that would attend the carrying out of regulations as to medical assessors or independent investigators. The words of the recommendation are, "That medical investigators should be appointed to inquire into the causes of all uncertified deaths." It must be remembered that an uncertified death does not necessarily mean that the deceased has died without any medical attendance, and due provision must be made for securing the attendance and the payment of the medical man who may have looked after the deceased during the last illness. It may fall to him to make the post-mortem examination himself, while if the case resolves itself into one of, say, unusual poisoning where special assistance is necessary, he should be summoned to the aid of the official medical investigator. But we may hope that there will be a quick response to the urgency of correct registration of the real causes of death and of actual inspection of the body by the person who signs the certificate. The public as well as the medical profession is in a state of uncertainty because of the conviction that things are at present in a state of confusion. A movement for reform is now backed up by medical concurrence, for the most part well considered, and we may reasonably expect action to follow.

Annotations.

"Ne quid nimirum."

LORD LISTER'S EIGHTIETH BIRTHDAY.

Lord Lister's eightieth birthday, which fell on Friday last, April 5th, was the occasion of his receiving congratulatory letters and addresses from all parts of the world. To this universal tribute the congratulations of THE LANCET may be very sincerely added. A meeting was held at the Royal College of Surgeons of England on April 4th, under the chairmanship of Mr. Henry Morris, the President of the College, with the object of deciding upon a means of celebrating the anniversary. Our readers are aware that the decision had already been arrived at by the committee appointed to make a fitting recognition of the anniversary to republish Lord Lister's works. The following gentlemen were appointed as an editorial committee: Sir Hector O. Cameron, Mr. W. Watson Cheyne, Mr. Rickman J. Godlee, Dr. Dawson Williams, and Dr. O. J. Martin. It was also agreed to preface the volumes with a sketch of Lord Lister's scientific work, so that the various steps in his discoveries may be rightly appreciated. This sketch is to be in no sense a biography of the man, but is to represent his work in due sequence, so that the reader may understand the development of the doctrines which led to the revolution of surgery.

CANNED MEATS AND "PTOMAIN" POISONING.

IN connexion with the American "packing-house scandals," which received so much public attention last year, questions have been raised as to the risk which is entailed by eating canned meat which, before being cooked, has been exposed to uncleanly conditions leading to contamination by the "meat poisoning" bacteria. It is sometimes represented that the objection to such foods may be well founded on wholesome sentiment, but is not strongly supported by evidence of actual poisoning. This view appears to be based mainly on three considerations: 1. Cases of poisoning due to canned meat foods do not often come to the notice of medical officers of health or sanitary authorities. 2. In well-known outbreaks of poisoning by prepared meat such as the Mansfield "potted meat" and the Derby pork-pie epidemics, the food in question has not been canned, and apparently the contamination of the meat has taken place after cooking. The illness which has resulted has been due, principally at all events, to infection by living bacteria of one or another kind, especially the bacillus enteritidis of Gaertner, and the symptoms of poisoning in most cases have appeared only after a definite incubation period during which the bacilli have multiplied within the body of the patient. 3. Canned meat foods have nearly always been subjected to a high temperature for a period sufficient to kill the bacteria in question. These facts can readily be admitted, but they by no means justify the conclusion sought to be drawn from them. It is obvious that the effects of a batch of contaminated canned meats could never be traced in the same way as a batch of pork pies which have all to be consumed within a few days of being made, and mainly by persons living in a few localities. The canned-meat poisoning, when due to toxin and not to living bacteria, produces symptoms which come on within a few hours at most and in all but the severest cases pass off comparatively quickly as the toxin becomes eliminated. Milder cases probably often do not come under medical treatment at all, while medical practitioners who see isolated instances of "ptomain" poisoning are under no obligation to report them to the sanitary

case of the drivers of motor omnibuses the question is particularly important, not only because the guidance of these monstrous machines through streets congested with traffic demands so constant an exercise of attention and judgment, but also because the chauffeurs under the new dispensation are necessarily influenced to some extent by the tradition of industrial drinking which flourished amongst their predecessors of the whip and which may still be fostered by the continuance of the practice of selecting public-houses for stopping places. In the interest of the public security it is not too much to demand that men while in the actual discharge of such responsible duties shall not be permitted to take alcoholic liquors. Nor should the approximate attainment of this ideal present any very great practical difficulty; engine drivers and chauffeurs already for the most part wear a distinctive dress and it would therefore be comparatively easy to make it a penal offence for a licence-holder to serve them with liquor while on duty." A similar prohibition applying to police constables in uniform was advocated in both the majority and the minority reports of the last Royal Commission on the licensing laws and the recommendation will no doubt be embodied in the Bill which is to be brought before Parliament this session. All that would be needed, therefore, to secure the measure of prohibition advocated by our correspondent would be to extend this clause so as to make it apply also to railway and motor drivers under similar conditions. The suggestion appears to us interesting and worthy of attention, but we think that more evidence than is at present under our hands connecting accidents in mechanical traffic with the drinking habits of the drivers must be forthcoming before any change in the law will be made.

POISONING BY CHEESE.

It is only occasionally that cases of poisoning by cheese are recorded, which is, perhaps, somewhat remarkable considering how readily toxins develop in stale milk. The conclusion would seem to be justified that, on the whole, the manufacture of cheese is conducted with due regard to hygienic considerations. As far back as 1683 a toxic principle known as tyrotoxin was separated from cheese which on being eaten had given rise to severe toxic symptoms. The same substance was extracted from stale acid milk. It proved to act as a violent poison, producing sickness, diarrhoea, and muscular spasms. There is little doubt, however, that similar symptoms had been traced to cheese long before the date that tyrotoxin was recognised.¹ We published an article which appeared in THE LANCET of March 28th, 1829, under the heading of a "Case of Poisoning by Cheese," in which a whole family, consisting of a middle-aged man, his daughter, a girl aged ten years, and a female relative about 60 years of age, had been suddenly seized with symptoms of poisoning as violent colic pain, vomiting, diarrhoea, and tenesmus, within an hour of eating a cheese recently bought. Another family who had purchased cheese from the same shop were attacked in a similar way. In those days the methods of chemical analysis were necessarily less refined than they are at the present time; nevertheless an examination of the cheese and of the vomited matters led to the extraction, by means of alcohol, of a substance which, from the description given, was evidently identical with the toxic substance now known as tyrotoxin. Since that date several instances of poisoning by cheese have been recorded and in every case a poisonous principle has been extracted which has proved to be identical with tyrotoxin. We have occasionally examined specimens of cheese which were suspected to contain copper, but the presence of this metal proved on the whole to be rare, while in cheese which had

occasioned irritant poisoning there was obtained an extract suspiciously like tyrotoxin and which at any rate responded to the chemical tests which are regarded as characteristic of that substance.

THE AFTER-CARE ASSOCIATION FOR POOR PERSONS DISCHARGED RECOVERED FROM ASYLUMS FOR THE INSANE.

THE After-Care Association has recently issued its report for 1906. This report again illustrates the excellent work done by this society in finding work for and in other ways assisting poor persons who have recently been discharged recovered from asylums and mental hospitals. Experience has demonstrated that many patients discharged from asylums and hospitals for the insane are quite capable of work if suitable occupation be found for them, but are unable to stand the anxiety and strain of procuring it for themselves. During the year 1906, 308 applications (184 for women and 124 for men) for assistance were received, which again shows an increase compared with former years. The report states that of these "many have been assisted as in the past by being boarded out in cottages in the country, by grants of money or clothing, and by finding occupation or in other ways as the council has thought best." This association is almost entirely dependent upon annual subscriptions and donations for carrying on its useful and charitable work. Many persons have a relapse of their mental illness largely owing to the difficulty that they experience in finding occupation after a nervous breakdown, and efforts for restoring such individuals once again into the ranks of workers deserve every support, especially when we realise that it is the only charity of the kind in the United Kingdom. We note that contributions of clothing and money are gratefully received by the association secretary, Mr. H. Thornhill Roxby, Church House, Dean's Yard, Westminster, London, S.W.

DUST REMOVAL AND A DIFFICULTY.

THE Marylebone borough council in its endeavour to fulfil its duty by removing the dust and refuse from a house in the Marylebone-road has met with a difficulty of an unusual character. Two women occupy respectively the basement and the ground floor, and to one of them the accumulation of dust is apparently due, but each denies that she is responsible for it. This, it might be supposed, would scarcely be of great importance as the council's dustman would remove the dust with impartiality to whichever it might be said to belong. There are, however, two ways by which it can be carried out to the dustcart, the one passing through the basement and the other along the ground floor, and each woman refuses to permit the dustman to take through her passage refuse which, she says, is due to her neighbour, although the one living on the ground floor will allow him to enter. The solicitor acting for the borough council has applied for a warrant, to which he is entitled if he proves a "refusal or failure to admit" to premises from which refuse ought to be removed, but Mr. Plowden has declined to interfere on the ground that the refusal has been not to admit but to permit to pass out. The last time the subject was mentioned in his court he proposed to send a constable "to show himself at the door," in the hope presumably that the minatory presence of a police officer would induce one or both of the recalcitrant occupiers to give way, and he seemed seriously to be of the opinion that his powers ended there, although inclined to be jocular in criticising the situation generally. If the difficulty has arisen through the borough council having failed to attach responsibility for the dust upon either of the strong-minded ladies who have resisted it, we can understand a temporary failure on its part to

¹ "Looking Back," THE LANCET, March 30th, p. 934.

which Sir Claude Macdonald excused the appointment of a foreigner by saying that he had been unable to find a British practitioner suitable for the post, and we further said that Dr. Wunsch's position was peculiar. Some 18 months have elapsed and the position, so far as we know, is unaltered. We now learn that the question will probably be raised in the House of Commons, and while we consider that an unregistered practitioner should not hold such a post as medical officer of an embassy we must not be taken to imply that Dr. Wunsch is in any way unfitted for the post so far as his professional knowledge is concerned. Whether it is right from a question of high politics that a foreigner should be practically a member of a staff under the British Foreign Office is not a matter upon which we have any knowledge to speak.

BAPTISM EXTRAORDINARY.

OUR Vienna correspondent forwards a story which many might be tempted to regard as a unique instance of religious bigotry. The circumstances were that at a hospital in Salzburg an operation had to be performed upon a woman in the third month of pregnancy. It was decided to induce abortion on account of eclampsia, but during the operation it was found necessary to remove the entire uterus. The nurse in attendance was a nun and she asked the surgeon to open the uterus before removing it and to baptise the fœtus. As the surgeon refused to do so she became very persistent, urging him to "abide by the laws of religion." At last an assistant made the ingenious suggestion that the baptismal water should be drawn up into a Pravaz syringe and then injected into the uterus, thus baptising the fœtus. This was accordingly done, the surgeon justifying his action by saying that "the conscience of the holy sister was thereby satisfied without anything being done to endanger the life or the prospects of the patient." A reference to a work that has long added to the gaiety of nations will prove that history has once more repeated itself, as witness these lines from the twentieth chapter of "The Life and Opinions of Tristram Shandy": "Madam, be pleased to ponder well the last line but one of the chapter where I take upon me to say, 'It was necessary I should be born before I was christened.' Had my mother, Madam, been a Papist, that consequence did not follow." And this statement the sly Sterne upholds in the following footnote: "The Romish Rituals direct the baptizing of the child, in cases of danger, before it is born; but upon this proviso, That some part or other of the child's body be seen by the baptizer:—But the Doctors of the Sorbonne, by a deliberation held amongst them, April 10th, 1733,—have enlarged the powers of the midwives by determining, That though no part of the child's body should appear,—that baptism shall, nevertheless be administered to it by injection,—*par le moyen d'une petite canulle*,—Anglicè *a squirt*.—'Tis very strange that St. Thomas Aquinas, who had so good a mechanical head, both for tying and untying the knots of school-divinity,—should, after so much pains bestowed upon this,—give up the point at last, as a second *La chose impossible*.—'Infantes in matris utero existentes (quoque St. Thomas!) baptizari possunt nullo modo.' O Thomas! Thomas!" The chapter finishes with a copy of the original French memoir presented to the reverend doctors by "un Chirurgien Accoucheur," and the weighty deliberations by which they felt themselves entitled to overturn the patristic authority. So scared, however, were these worthy prelates of a too hasty iconoclasm that they added this rider: "Dependant comme il s'agiroit, en autorisant la pratique proposée, de changer une règle universellement établie, le Conseil croit que celui qui consulte doit s'adresser à son évêque, et à qui il appartient

de juger de l'utilité, et du danger du moyen proposé, et comme, sous le bon plaisir de l'évêque, le Conseil estime qu'il faudroit recourir au Pape, qui a le droit d'expliquer les règles de l'église, &c." It would be hard to discover a stranger concurrence between religion and science and we can only hope that the evolution of modern thought will prevent the recurrence of a practice that appears equally discreditable to both.

ALCOHOL AND TRAFFIC ACCIDENTS.

THE recent occurrence of several railway catastrophes in which the fault has apparently lain with the human factor on whose integrity, however cunning be our mechanisms, we must in the last resort place our reliance, has drawn attention in a very forcible manner to the need of exercising a closer supervision than has hitherto been customary of the various conditions that may interfere with the nervous efficiency of persons in responsible charge of locomotive machinery. Of these conditions the use of alcohol is notoriously one of the most important, one of the most frequently operative, and one of the most controllable. Nowadays, with the high speed of railway travel and the increasing complexity of railroad systems, with the extension of the use of electric traction, and with the ever-growing numbers of motor omnibuses hurtling through our streets the appalling risks that may accrue from the intoxication of an engine-driver or a chauffeur are too obvious to need mention. But what is not so clear to the public mind is that, even when its effects fall far short of overdrunkenness, a too free use of alcohol exercises an influence on nervous function which is sufficiently serious to make a very questionable whether it should be allowed in such circumstances to men while actually engaged in such avocations. The researches carried out by Kraepelin and his pupils, and published in the "Psychologische Studien" edited by that distinguished alienist,¹ confirmed as they have been by the investigations of other observers, have, in fact, conclusively shown that, at all events in a large proportion of individuals, even relatively small doses of alcohol diminish very materially the extent and the accuracy of visual perception. When, for instance, series of letters, figures, and syllables are exposed for short periods of time to the eye of an observer who endeavours to identify them, it is found that the errors and still more the omissions, become much more numerous after the ingestion of even so moderate a quantity of alcohol as would be equivalent to little more than a pint of "four ale." With larger doses, of course, the disturbance of perception is proportionally more pronounced. When it is further borne in mind that, at the same time that it thus obscures the perceptions on which judgment is founded, alcohol also accelerates the motor impulses which translate that judgment into action, it is easy to see how much it may contribute, and doubtless very often has contributed, to the commission of fatal errors in the driving of an express train or a motor. With such evidence before us we need not incur the reproach of being teetotal faddists if we suggest that the drinking habits of chauffeurs and engine-drivers ought to be under stricter control, and that when the law requires that such persons shall not be under the influence of liquor, that time-honoured phrase should be interpreted in the sense of the experimental psychologist rather than in accord with the less exigent standard of the police constable. A correspondent whose communication has led us to make these remarks recognises that though the psychologist uses absolute alcohol in his experiments, yet he employs it in doses corresponding to those which the workman imbibes in his beer. We may conclude the consideration of a most important subject by quoting his own words. "In the

¹ Engelmann, Leipzig, 1896 et seq.

old, indeed, be that no "optician" should be permitted to set an "optical" defect until a certificate had been obtained from a medical practitioner that the defect in question was either increased nor complicated by disease. This is, in reality, the last word to be said upon the question; unless it be that, upon the whole, it would probably be better for a child to be left to struggle with his or her visual difficulties than that the correction of the defects by which these difficulties are produced should be committed to the hands of anyone incapable of dealing with them by the light of scientific and pathological knowledge.

A SIMPLE TEST OF THE PURITY OF CHLOROFORM.

CHLOROFORM is so easily decomposed by the action of air, light, and moisture that it is important for the surgeon to be able to verify its purity for himself. The decomposition of chloroform is always accompanied by the production of hydrochloric acid, but in the early stages of decomposition the presence of minute traces of the acid is not always detectable by silver nitrate. In a recent number of the *Revue Médicale* M. Breteau and M. Woog have described a simple test of the purity of chloroform. A small cylinder of elder pith is dyed in a saturated solution of Congo red in absolute alcohol and placed in the chloroform. If decomposition has only just begun this indicator serves to detect it by changing rapidly in colour from bright red to blue, owing to the presence of hydrochloric acid among the products of decomposition. We have tried this method and have found it to be extremely delicate. It can be recommended as an automatic indicator of the purity of chloroform, whether kept in a midwifery bag or in the shelves in a surgery. By dyeing the pith the chloroform does not undergo contamination with the colouring matter. A piece of the dyed pith should be put into a bottle of chloroform when it is first opened and kept there until the bottle is empty. It can be used over and over again so long as it remains bright red in colour. M. Breteau and M. Woog call attention to the danger of inclosing chloroform in ampoules or sealed glass bulbs, owing to the decomposition of traces of chloroform around the point where the glass is sealed. Each ampoule, they consider, should contain a minute plug of dyed elder pith in the glass stem to indicate the condition of the chloroform when it is required for use. The impurities may be removed by distilling the chloroform over lime or by shaking with caustic soda solution.

TUBERCULOUS MENINGITIS WITHOUT TUBERCLES.

At a meeting of the Société Médicale des Hôpitaux of Paris on March 15th M. A. Siredey and M. Tinel called attention to the fact that although tubercles of various forms anatomically characterise tuberculosis, yet in some cases they are absent. This is especially true of the tuberculosis of the central nervous system. Armand Delille has shown that the classical symptoms of tuberculous meningitis may be present and yet tuberculous granulations of the meninges may be absent. A diffuse bacillary infiltration, and even the tuberculous toxins, may provoke tuberculous meningitis. Though these facts are well known to experimental pathologists they often cause surprise to practitioners. Hence the interest of the following case. A boy, aged 16 years, was admitted into hospital comatose on Oct. 31st, 1906. He had been ill for a fortnight with headache and vomiting and gradually became comatose. Rigidity of the neck, photophobia, wasting, mydriasis, irregularity of the pulse, the meningeal streak, Kernig's sign, and lesions at the apices of the lungs left no doubt as to the diagnosis of tuberculous meningitis. Lambar puncture

showed marked lymphocytosis of the cerebro-spinal fluid and some polynuclear cells. The case ran the ordinary course, and death occurred on Nov. 11th. At the necropsy the most minute examination failed to show any tubercles on the meninges or in the cerebral cortex. To the naked eye the changes consisted in an intense congestion of the nervous centres of which the vessels were much distended. The meninges had lost their transparency and at several points showed a slight thickening with a milky tint, little pronounced. The meninges could be raised without tearing the adjacent cerebral substance. The subarachnoid space and the ventricles contained a notable quantity of liquid. The lungs showed diffuse tuberculous lesions, large granulations of the size of a lentil confluent in some places, disseminated in others. Microscopic examinations revealed numerous tubercle bacilli in these granulations. To the naked eye the kidneys showed nothing abnormal but the microscope disclosed little tuberculous nodules. Microscopic examination of the meninges showed a diffuse leucocytic infiltration without any tuberculous granulations. In some places the cells were agglomerated into little nodules, but nowhere was there a definite tubercle. The cases exactly corresponded to the type described by Delille as "diffuse leucocytic infiltration, predominantly perivascular, and with tendency to nodules." In no preparations could giant cells or caseous degeneration be seen—nothing suggestive of formation of tubercles. But a large number of tubercle bacilli was disseminated wherever there was leucocytic infiltration of the membranes. They were especially grouped around the blood-vessels, forming in certain places little agglomerations without modification in the form or grouping of the neighbouring cells.

PATENTS FOR CHEMICAL INVENTIONS.

It was recently pointed out in the columns of THE LANCET by a legal contributor that it is possible in this country to obtain patent rights in perfectly well-known chemical processes for the production of medicinal compounds. For example, a patent was granted last year in respect of the manufacture of eserine sulphite by the action of sulphurous acid on the alkaloid, although that process had been known for many years and is the one which any chemist would naturally use. The fault has been that the Comptroller of Patents, while compelled by the Patents Act of 1902 to have the records of previous specifications searched when a patent is applied for, has had no power to entertain an objection on the ground of want of novelty unless the process has actually been anticipated in a prior patent specification. This defect of the law will be remedied if the Patents and Designs Bill, introduced in the House of Commons by the President of the Board of Trade, is passed in its present form by Parliament. Clause 6 of the Bill enlarges the grounds of opposition to the grant of a patent by providing that an application may be opposed before the Comptroller on the ground "that the invention has been published in this country prior to the date which the patent would bear if granted." The Bill also contains a clause giving the Comptroller powers to demand the submission of samples in the case of patents for chemical inventions. The necessity for this clause has arisen from the fact that in the past some patentees have framed their specifications in such a way as to secure proprietary rights in whole classes of imaginary chemical processes and have not tried to make all the substances covered by the specifications. Trouble has subsequently arisen when real inventors have found their inventions shut out by one of these roving prior claims. So far as Mr. Lloyd-George's Bill tends to prevent the unfair assumption of

secure its object. We find it less easy to believe that Acts of Parliament and local by-laws which provide for the compulsory admission of scavengers or any other persons to places where it is desirable that they should go, do not thereby give them the power to pass out and complete the work for which they are admitted. Apart from the question arising out of the presence of two occupiers referred to above, Mr. Plowden can hardly mean that the ordinary householder can with safety admit the dustman to his premises and defeat the intention of the law by refusing to let him leave them carrying the dust. The *impasse* so created would resemble that suggested by the clergyman who, when he was told that the Prayer-book must be taken to forbid that which it did not in express terms order or permit, asked what then was to be done at a baptism, in regulating which the rubric directed him to "take the child into his hands" but said nothing about his giving it back. A divisional court should be able to solve the problem raised by Mr. Plowden's literal interpretation of the phrase employed should the point be brought before it by an appeal.

THE RELATION OF HOSPITALS TO THE EMPLOYERS' LIABILITY ACT.

IN the *Times* of April 8th an admirable letter appears from Mr. Michelli, secretary of the Seamen's Hospital, Greenwich, pointing out a way in which the new Workmen's Compensation Act may inflict a real injustice on our general hospitals. In repeating the substance of his letter we desire strongly to endorse his argument. It is quite obvious that all hospitals which treat accident cases have in the past restored to health quickly many injured working people who would otherwise have been for a prolonged period a charge upon employer or insurance company; it is equally certain that under the new Act the assistance thus rendered to the latter will be very materially increased and, at the expense of their supporters, the hospitals will save many thousands of pounds for employers of labour and insurance companies. Unfortunately, past experience has not shown that such impersonal, though none the less real, obligations are frequently taken to heart by those who should feel the responsibility of them, and the case upon which Mr. Michelli has based his letter shows no exception to the rule. It appears that a very large employer of labour in South-East London addressed an equally important insurance company suggesting that the latter should contribute to the Seamen's Hospital on the considerations that we have set down above. The appeal met with a flat refusal, based upon the ingenious argument that in fixing the premium to be paid by the firm "they had taken all existing circumstances into consideration"; this letter was written by order of the directors, who thereby tacitly acknowledged that in the conduct of their business affairs they considered themselves entitled virtually to appropriate a subsidy from the pockets of the charitable public. This begins ill enough, but worse remains behind, for—we quote Mr. Michelli's own words: "The hospitals will suffer most by the withdrawal of support that will follow the enforcement of the Act. Employers of labour who hitherto have contributed to the hospitals in recognition of services rendered to their employees are now notifying the withdrawal of their contributions, as they will have to provide for compensation under the Act, and they feel no longer any obligation (moral or otherwise) to support the hospitals." It would thus seem that the Act may prove a double-edged weapon to assail hospital treasures, and it will tax the resources of secretaries and committees to guard against it if those who have power to wield it do not temper might with right. Fair play undoubtedly demands

that each insurance company should pay towards the maintenance in hospital of men to whom compensation is due, for it is to meet medical and nursing expenses that such compensation goes when it is awarded to an individual who is treated in his own home. It will probably be a difficult task to get insurance companies as a whole to recognise the justice of this appeal, but something may be done by its being pointed out to individual members of their boards of directors, and this office we trust that some of our readers may, as opportunity occurs, take it upon themselves to carry out.

EPIDEMIC CEREBRO-SPINAL FEVER.

GLASGOW and Belfast continue to supply many cases of epidemic cerebro-spinal fever, but in most other localities where it has made its appearance the attacks are comparatively few. In London a recently published report by the medical officer of health of Stepney states that six cases have occurred in that borough during the last six weeks and that four of them have terminated fatally. Cases have also been reported at Salford in Lancashire, at Hanley and Tipton in Staffordshire, and at Oldbury in Worcestershire. In Glasgow there have been 61 deaths from the disease during the fortnight ended April 3rd, and on that day there were 110 cases under treatment. Cases have also been reported in Edinburgh, in Kilmarnock, in Dunfermline, and at various places in Aberdeenshire and Banffshire. In Belfast eight deaths occurred during the week ended April 3rd and on that day 40 patients were under treatment. On April 3rd the medical officer of health of Dublin stated that there had been no case of the disease in that city for a fortnight and that the total number in two months had been only 18.

CHILDREN'S SIGHT AND SPECTACLES.

AT a recent meeting of the subscribers to the Bristol Eye Hospital attention was called in the report to the amount of time devoted by the staff to the work of testing the eyes of school children, a work from which the committee desired to see its officers relieved. The publicity given to this desire has called forth a letter to the local papers from a correspondent named Dunscombe, who is possibly an optician, and who informs his readers that "none of the work complained of need go to the hospital; it is the work of the optician, and Bristol has qualified opticians capable of testing and correcting defects in vision, who would send all cases of disease and abnormality to the hospital, or an oculist, according to the circumstances of the person." It is difficult to imagine that this statement proceeds, as we would fain suppose, from honest ignorance. In children's eyes, especially in the large class which are tending to pass from hypermetropia into myopia, it is hardly possible to draw any line between disease and mere malformation; and the treatment required by the former has constantly to be combined with the optical aids called for by the latter. The attempt of opticians to obtain recognition of themselves, either from Parliament or by charter from the Privy Council, as persons qualified to "test sight," has so far failed; and it called forth from the General Medical Council an emphatic denial of the justice or validity of the claim. That body, in its report to the Privy Council on the subject, pointed out that "the admission of the petitioning opticians that 'where defective vision is due to other than optical conditions it should be treated by a duly qualified medical practitioner' was fatal to the rest of their contention, not only because, as a matter of fact, optical defects and diseased conditions constantly overlap and complicate each other but also because the latter cannot be either certainly recognised or certainly excluded by any but a medical practitioner." The natural corollary of the admission

guarantee of a true finding of the cause of death is clear from the ludicrous, and I trust exceptional, examples quoted before the Parliamentary committee—viz.: 1. "Death from stone in the kidney, which stone he swallowed when lying on a gravel path in a state of intoxication." 2. "Child, three months old, found dead, but no evidence whether born alive." It is believed that bodies are disposed of as still-born which are, in fact, those of live-born children, thus opening the door for crime, as the still-born are regarded by the law as non-existent. Again, the local registrar is appointed by one authority, controlled by another, and neither of these is the authority which appoints and pays the coroner. The local registrar is often unversed in medical terminology. Such a certified cause of death as the classical barbarism "angio-leucitis" might well overawe a local registrar, while it might also cover a case of blood poisoning, due to preventable cause. Then, again, the coroner's officer is an official unknown to the law and often little acquainted with medicine or law, yet he makes the delicate preliminary investigations on which the decision whether to hold an inquest or not is based. In some instances such officials have been found to be corrupt as well as uninformed. The percentage of reported cases in which inquests are held even in London varies from 90 in Westminster to 70 in a southern district of London. Even coroners are not always proficient in law and in medicine, though the London County Council in its recent appointments has endeavoured to secure men with the double qualification. As Lord Herschell once observed, "Certain legal and judicial qualities are essential to the efficient discharge of the coroner's duties. If you can find them pre-eminently in a medical man by all means appoint him; but I own I should no more expect to find them there than I should expect to find amongst my brethren of the bar one skilled in the diagnosis of disease." The Medico-Legal Society would therefore respectfully press upon your lordship that the law should be amended so that: (1) no human body, whether of one born alive or still, should be buried or otherwise disposed of without a certificate either by a competent medical man or by a coroner; (2) that such certificate should show the fact of death as well as its cause and also vouch for the identity of the deceased; (3) that specially qualified and independent medical men should be appointed as medical investigators or assessors to assist the coroner in preliminary inquiries, in scrutinising the causes of death, and in post-mortem examination; (4) that mortuaries with proper equipment for thorough investigation into the causes of death should be provided under the same authority as makes disbursements for inquests; (5) that the records of all such inquests should be public property; sixth and lastly, the society calls attention to an incidental advantage that should arise from such reforms—viz., the development of a school of medical jurisprudence in London worthy of the metropolis and associated with its University. This country has lagged behind France and Germany in the study and teaching of forensic medicine. The first work in English on the subject appeared in 1787, the first chair in Britain was founded at Edinburgh in 1801. Fodere, Orfila, and Tardieu had developed the science and Caspar in Germany had codified our knowledge in his classical work. By united effort and under improved administration a worthy school of forensic medicine should arise in London. We ask your lordship respectfully to give your best attention to these considerations. In turning over the pages of the autobiography of my kinsman, Sir Samuel Romilly, I alighted the other day on this passage: "Whatever just reforms are to be made in the civil and criminal jurisprudence of the country are wholly in the power of a Lord Chancellor." It is, my lord, because we fully realise the truth of that observation that we ask you, unlike your noble predecessors who, either from want of inclination or lack of opportunity, have left the Select Committee recommendations undealt with, to give your early and earnest consideration to securing a remedy for the unsatisfactory state of things which we have felt it our duty to lay before you.

The Lord Chancellor, in reply, promised to personally investigate the facts and to give his serious consideration to the whole matter laid before him.

MEDICINE AND THE LAW.

Dangerous Dogs and the Law.

RABIES has been stamped out in Great Britain by regulations which cause inconvenience to no one except those who are desirous of importing foreign dogs or who insist on dragging their pets about with them when they travel. Further advance towards securing the safety of those who do not keep dogs themselves has been made by two recent decisions in the King's Bench Division and by the publicity given to them. The first of these laid down no new version of the law, but only gave a final blow to a time-honoured superstition which has been kept alive by the catch-phrase to the effect that a dog is "entitled to his first bite." In the case in question a firm of dressmakers kept a Chow bitch in the garden behind their premises, which on the occasion complained of got into one of the workrooms and bit an apprentice. The county-court judge found as a fact from evidence before him that the bitch had a propensity to be vicious, either generally or when she had puppies (as she had at the time when she bit the plaintiff), and awarded damages accordingly, although there was admittedly no evidence that any one had been bitten by her before. In dismissing the defendant's appeal Mr. Justice Darling said that it was not necessary in such a case to show that the owner of the dog knew that it had already bitten someone or that it had in fact bitten someone. It was only necessary to prove knowledge by the defendant that the dog was likely to bite without provocation, either in particular circumstances or generally. Mr. Justice Lawrence concurred in this view and the same two judges a few days later, sitting with the Lord Chief Justice, had another case before them in which also a dog was concerned. On this occasion a man had been summoned for not keeping a "dangerous" dog under proper control, but the justices had refused to convict, after excluding evidence that the dog had been seen to kill lambs. The court, after referring to the case already mentioned, held that there was no reason why the word "dangerous" should have its meaning limited to danger affecting human beings and sent the case back to the magistrates to be further heard. These two decisions have, we believe, to some extent anticipated a private Bill dealing with dogs, the passing of which might have been postponed indefinitely, and they should have a wholesome effect if they cause those keeping vicious pets to consider their position. Hitherto many selfish people have been in the habit of disregarding the fears and even the remonstrances of their neighbours, secure in the knowledge that their dogs have not yet bitten anybody and being no doubt also of the opinion that the "first bite" would not be inflicted on their own persons.

Experiments as Legal Evidence.

Inquest juries repeatedly have to take refuge in a self-evident "open verdict" in cases where there is insufficient evidence adduced to enable them to decide whether the deceased met his death by an accidental or a homicidal act, the latter, of course, including an act of self-slaughter. The evidence of eye-witnesses of the fatal deed is rare, so that the decision rests on the balance of probabilities. Where the inquest closes the matter little harm is done by returning either an open or a definite verdict, but where proprietary claims may follow upon the death greater care is needed in arriving at or near the truth. Then the opinions of expert witnesses may be heard for what they are worth. Now an expert witness is one who poses as an authority on a given subject from the fact that he has devoted considerable time and study to that particular theme, and usually he has qualified to bear technical testimony by having made many personal tests and experiments bearing on the matters in dispute. The case of *Thackman v. The Brotherhood of American Yeomen*, recently tried in the North-Western courts of the United States of North America, gives an instance where previous experimentation by a witness was allowed to give him a status in court as one able to throw light upon a disputed cause of death. The action was on a mutual benefit certificate under which a claim was made but contested by the defendants on the ground that the assured deceased had put an end to his own life. It appeared that the deceased was seen to go into a barn to get his team; he was discovered an hour later dead, being asphyxiated by the neck from a tie strap attached to a bridle which was hanging on a peg whereon the deceased usually

LONDON TEMPERANCE HOSPITAL.—H.R.H. Princess Louise, Duchess of Argyll, has consented to open the new out-patient hall of the London Temperance Hospital on Tuesday, May 14th next.

proprietary rights in chemical processes and products which are of medicinal value, it will command the approval of the medical profession. The Bill does not affect so-called "patent medicines," which are rarely made under Letters Patent, but it may reduce to some extent the number of proprietary foreign-made synthetic remedies with which the drug market in this country is flooded at the present time.

THE next meeting of the Northern and Midland division of the Medico-Psychological Association of Great Britain and Ireland will be held, by the courtesy of Mr. F. Perceval, at the Lancashire County Asylum, Prestwich, near Manchester, on Thursday, April 18th, at 2.30 P.M. Dr. Bedford Pierce of York is the honorary secretary of the division and communications should be made to him.

His Grace the Duke of Northumberland, K.G., President, is to preside at the annual dinner of the Royal Sanitary Institute to be held at the Langham Hotel, London, on Wednesday, May 15th.

DEATH CERTIFICATION AND THE AMENDMENT OF THE CORONERS ACTS.

In our issue of March 30th we mentioned that the Lord Chancellor had received a deputation from the London County Council and the Medico-Legal Society. Mr. H. T. Anstruther, chairman of the London County Council Public Control Committee, represented the former body, and Sir William Collins, M.P., a former President of the Medico-Legal Society, represented the latter. We now print below the abstract of recommendations handed in to the Lord Chancellor by Mr. Anstruther, and the speech upon the points in question delivered by Sir William Collins, and we comment upon the proceedings in a leading article which appears at p. 1027:—

MR. ANSTRUTHER'S REPORT.

Notes on Council's Resolutions of 30th October, 1906.

Deputations from the Council attended before previous Lord Chancellors upon this subject in February, 1895, and November, 1896. On the first occasion Sir G. Harrie and Dr. (now Sir William) Collins addressed Lord Herschell. On the second occasion Mr. Haydon and Dr. Collins addressed Lord Halsbury. The Council has had ample opportunity for obtaining a knowledge of the subject. It is the only local authority in London with any jurisdiction in connexion with the holding of inquests. With certain exceptions, applying to about one-twentieth of the London area, the appointment of London coroners is vested in the Council. Their salaries and other inquest expenses are paid by the Council, and the Council has to provide coroners' courts and arrange coroners' districts. These important functions have been carried out for 18 years, and the relation of these questions to the needs of London to-day as compared with the position in 1889 when the Council was first charged by Parliament with the duties, show that the Council's proposals are founded on experience. They are also based on an examination of admittedly better conditions and systems prevailing elsewhere.

Notes on the Earlier Recommendations.

The Council has linked this subject with that of death certification. It is almost impossible to separate them and the Council in its conclusions has been largely assisted by the labours of the Death Certification Committee of the House of Commons of 1893. With the recommendations of that Committee the Council is in general agreement, and has incorporated in its scheme such of the recommendations as appear to bear directly upon the question of coroners' inquests. The report of the Inter-departmental Committee on Physical Deterioration also included one or two valuable suggestions having a connexion with coroners' inquests, and these have also been embodied in the Council's proposals. It has been suggested that there should be a dual delegation of duties in connexion with death certification: one to the registrar as at present but merely for the collation of vital statistics; the other to the coroner who should have cognisance of all deaths and himself select those needing inquiry. The Council has not felt justified in advancing this view but it seems only fitting to refer to it. There is no doubt that the machinery which should insure notice to the coroner of the cases contemplated by the statute is very imperfect, and there is a strong suspicion founded upon very substantial grounds that many cases escape notice which, if they had been notified, would assuredly have formed the subject of an inquest.

Notes on Individual Recommendations.

Recommendation 9.—When a proper medical certificate is wanting, the medical man concerned, or the relations and friends of the deceased, should be required to report the case direct to the coroner. It appears clear that every such case should, without delay, come under the cognisance of the coroner.

Recommendation 10 deals with cases of death after surgical operation. Both in the interests of the public and medical profession, such cases should automatically come to the notice of the coroner, though, of

course, not necessarily with a view to an inquest being held in all such cases.

Recommendation 11 is perhaps the most important of the Council's recommendations—viz., that medical investigators should be appointed to inquire into the cause of all uncertified deaths. The medical investigator the Council has in contemplation would be a highly qualified medical man, skilled in pathological work, and having no personal interests in private practice. One of the chief defects of the present system is in connexion with the preliminary inquiry, upon which depends the coroner's decision as to whether or not an inquest should be held. Legally speaking, the decision rests with the coroner, but in London at least, the cases reported to the coroner are so many that the collection of the facts upon which the coroner arrives at his decision is made by the coroner's officer, who is usually a police constable, and is also an officer unknown to the law. It is no exaggeration to say that these men are entirely without qualification for so important a duty.

When the Council first dealt with this work it had to take very strong measures with regard to certain of the coroners' officers, against whom the gravest irregularities were charged and proved. This fact is an additional argument for the assumption that in the preliminary work the coroner should have the assistance of skilled professional gentlemen, whose probity would be above question. The present medical assistance on which a coroner can count without reference to the authority which checks his disbursements is very restricted. Sections 21 and 22 of the Coroners Act of 1837, which deal with medical witnesses and their fees, are virtually a repetition of powers first provided in an Act of William IV. passed in 1834. The provision that may have met the needs of that time is now quite inadequate. Moreover, a coroner can only avail himself of it after the commencement of inquest proceedings, and never as an assistance in deciding whether or not an inquest is necessary. Even then it fails to insure that the medical assistance shall be sufficient for the coroner's purposes.

The Council has already had experience of a better system. It cannot authorise the spending of money in medical fees beyond the amounts prescribed in the Coroners Act of 1837, but a number of highly qualified medical gentlemen attached to London hospitals and skilled in pathological work have undertaken to carry out post mortem examinations in special cases at the ordinary fees. A panel has been formed of their names, so that London coroners may, in cases of difficulty, avail themselves of this valuable assistance. The experiment is, however, unequal in its application, incapable of application to the necessities of London as a whole, and only of assistance to the coroner when he has decided to hold an inquest. It does not assist him in the detection of cases that call for inquiry where there may be reason to suppose that the relatives of the deceased, and possibly in some cases the medical attendant, may wish to avoid publicity. Yet if the coroners' work is to be a reality (and not a sham) it is obvious that all cases should receive competent investigation and that the preliminary stages of inquiry are as important as open court proceedings.

Sir WILLIAM COLLINS said: My Lord, on the two previous occasions, to which allusion has been made by Mr. Anstruther, I have had the honour of voicing deputations to your lordship's noble predecessors on behalf of the London County Council; on this occasion, while generally endorsing the views which have just been laid before your lordship, I appear on behalf of the Medico-Legal Society, as a former president of that society. The Medico-Legal Society was established "to promote the advancement of medico-legal knowledge in all its branches." As a learned society it usually restricts its operations to debate and the discussion of papers, but it felt so strongly on the question now under consideration that it has deemed it its duty to take executive action. On July 25th, 1906, the society passed the following resolution:—

That the present methods of ascertaining the fact and cause of death are imperfect, constitute grave public danger, and call for early legislation with a view to amelioration of the law.

The present system we hold to be imperfect in two respects. Firstly, it is too limited in its purview, it only deals with reported cases, there being no security that among unreported cases, and indeed even among some certified cases, that there are not included deaths due to other than natural causes. Secondly, in cases that do come within the scope of the existing system its efficiency is impaired by the machinery employed, by the multiplicity of jurisdictions involved, with the result that the most painstaking and precise investigations are often applied where they are the least and not where they are the most required. The revelations made by the Death Certification Committee of 1893 exposed a public scandal which has remained for 14 years unredressed. The percentage of certified to total deaths varied from 1.2 per cent. in London to 8.5 in North Wales and (though the Scotch system is, of course, different) to 42 per cent. in Inverness-shire.

THE LORD CHANCELLOR: 42 per cent. What is the explanation?

Sir WILLIAM COLLINS: Yes; the Select Committee regarded it as astounding, but I have verified their report to-day. Possibly it is due to the scattered population finding it difficult to get a medical man within reach. Then the present form of death certificate requires only the cause and not the fact of death to be vouched for, and cases are not unknown in which the certified "deceased" is still in the land of the living. That a coroner's inquest is no certain

fever occurred in Glasgow and two in Edinburgh; and two of the three deaths from measles in the latter city. The deaths in the eight towns referred to diseases of the respiratory organs, including pneumonia, which had been 155, 147, and 123 in the three preceding weeks, further declined last week to 109, and were 33 below the number in the corresponding period of last year. The causes of 25, or 3·7 per cent., of the deaths registered in the eight towns during the week were not certified; in the 76 English towns the proportion did not exceed 0·8 per cent.

HEALTH OF DUBLIN.

The annual rate of mortality in Dublin, which had been 22·3 and 24·3 per 1000 in the two preceding weeks, further rose to 28·3 per 1000 in the week ending April 6th. During the 13 weeks ending March 30th, the death-rate averaged 27·2 per 1000, the rates during the same period being 19·2 in London and 19·6 in Edinburgh. The 212 deaths of Dublin residents registered during the week exceeded by 30 the number in the previous week, and included 15 which were referred to the principal infectious diseases, against 12 in each of the two preceding weeks; of these eight resulted from whooping-cough, three from measles, three from diphtheria, and one from "fever," but not any from small-pox, from scarlet fever, or from diarrhoea. These 15 deaths were equal to an annual rate of 2·0 per 1000, the death-rate last week from the principal infectious diseases being 1·9 in London and 2·4 in Edinburgh. The eight deaths from whooping-cough exceeded the number recorded in any previous week of this year; the deaths from diphtheria also showed an excess over the numbers in recent weeks; while the mortality from measles and from "fever" was slightly lower than it had been in the preceding week. The 212 deaths from all causes included 32 of children under one year of age and 50 of persons aged upwards of 60 years, each of these numbers being six in excess of the corresponding number in the preceding week. Seven inquest cases and four deaths from violence were registered; and 97, or nearly 45 per cent., of the deaths occurred in public institutions. The causes of five, or 2·4 per cent., of the deaths in Dublin last week were not certified; in London all the causes of death were duly certified, while in Edinburgh the proportion of uncertified deaths was as much as 4·1 per cent.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

Deputy-Inspector of Hospitals: W. Tait, to Hong-kong Yard. Staff Surgeons: A. E. Kelsey, to the *Diadem*, on recommissioning; and W. J. Codrington, to the *Isis*, on commissioning.

ROYAL ARMY MEDICAL CORPS IN INDIA

Lieutenant-Colonel D. O'Sullivan, on reversion from the 9th Secunderabad Division, is appointed to the command of the Station Hospital, Rawalpindi. Lieutenant-Colonel F. H. Treherne is appointed to the command of the Station Hospital, Sialkot. Major N. Tyscke to the command of the Station Hospital, Dalhousie. Captain L. W. Harrison to medical charge of Headquarters Staff and establishments, Northern Command. The following bill station appointments have been approved for the summer season of 1907: Major O. R. A. Julian, to command Station Hospital, Oherat; Captain J. M. H. Conway, to command of the Station Hospital, Kalabagh; Captain R. L. Argles, to command of the Station Hospital, Khya Gali; Captain R. Storrs, to command of the Station Hospital Camp, Barian; Lieutenant-Colonel D. M. O'Callaghan, to command of the Station Hospital, Kuldanna; Major H. N. Dunn, to command of the Combined Station Hospital for Khanspur and Ghora Dhaka; Captain W. D. O. Kelly, to command of the Station Hospital, Upper Topa; Lieutenant W. Benson, to command of the Station Hospital, Lower Topa; Lieutenant J. A. Turnbull, to command of the Station Hospital, Bara Gali; Major G. St. C. Thom, to command of the Station Hospital, Solon. The following officers have been granted leave: Captain W. F. Tyndale, on private affairs for seven months; Lieutenant-Colonel C. G. Reilly, for six months on medical certificate pending retirement; Lieutenant-Colonel B. L. Mills, seven months on private affairs; Lieutenant-Colonel A. L. F. Bate, seven months on private affairs; Captain W. M. Power, three months privilege in India; Captain

B. H. V. Dunbar, six months on private affairs; Major L. A. Mitchell has been granted extension of sick leave to August 18th, 1907. Lieutenant-Colonel M. B. Skinner, M.V.O., on arrival from England will be posted to Nowshera and appointed to the command of the Station Hospital there. Lieutenant-Colonel P. O. H. Gordon is transferred from Secunderabad to Burma Division, Lieutenant G. Ormrod from Eastern Command to Burma Division, Captain J. F. Whelan to Aden for duty in the Station Hospital, Captain J. W. Seccombe from Rawalpindi to Ambala for charge of Brigade Laboratory, Lieutenant-Colonel J. R. Stuart from Mount Abu to Neemuch, Captain E. W. Powell from Poona to Kirkee, and Lieutenant O. D. M. Holbrook from Kirkee to Poona.

ARMY MEDICAL RESERVE OF OFFICERS.

Surgeon-Lieutenant James O. Herbertson to be Surgeon-Captain (dated March 19th, 1907).

CHANNEL ISLANDS MILITIA.

The Royal Militia of the Island of Jersey.—Staff: Surgeon-Major W. Falla, Principal Medical Officer, to be Surgeon-Lieutenant-Colonel (dated Feb. 6th, 1907).

HONOURABLE ARTILLERY COMPANY OF LONDON.

Surgeon-Lieutenant-Colonel R. J. Beece is granted the honorary rank of Surgeon-Colonel (dated March 7th, 1907).

IMPERIAL YEOMANRY.

Fifeshire and Forfarshire: Alan Leonard Smith Take to be Surgeon-Lieutenant (extra) under the conditions of paragraph 28, Imperial Yeomanry Regulations (dated Feb. 27th, 1907). Worcestershire (the Queen's Own Worcestershire Hussars): Surgeon-Captain J. H. Bellby resigns his commission (dated Feb. 28th, 1907).

VOLUNTEER CORPS.

Royal Garrison Artillery (Volunteers): 1st Ayrshire and Galloway: John Aitken to be Surgeon-Lieutenant (dated March 15th, 1907).

Rifle: 4th Volunteer Battalion the Queen's (Royal West Surrey Regiment): Charles Spencer Palmer to be Surgeon-Lieutenant (dated Feb. 15th, 1907). 2nd Volunteer Battalion the King's (Liverpool Regiment): Supernumerary Surgeon-Captain J. G. Martin (on ceasing to do duty with the Liverpool Bearer Company, Royal Army Medical Corps (Volunteers), is absorbed into the establishment (dated Feb. 1st, 1907). 8th (Scottish) Volunteer Battalion, the King's (Liverpool Regiment): The undermentioned officer resigns his commission: Surgeon-Captain W. S. Henderson (dated Feb. 15th, 1907). 5th Volunteer Battalion the Royal Scots (Lothian Regiment): Surgeon-Major J. Mill to be Surgeon-Lieutenant-Colonel (dated Feb. 20th, 1907). 1st Volunteer Battalion the Royal Warwickshire Regiment: Surgeon-Captain O. Y. Flenwith resigns his commission (dated March 6th, 1907). 1st Volunteer Battalion the Royal Fusiliers (City of London Regiment): Surgeon-Lieutenant-Colonel H. G. Thompson (Brigade Surgeon-Lieutenant-Colonel, Senior Medical Officer, Royal Fusilier Volunteer Infantry Brigade) is granted the honorary rank of Surgeon-Colonel (dated March 4th, 1907). 2nd Volunteer Battalion the Duke of Cornwall's Light Infantry: Surgeon-Major and Honorary Surgeon-Lieutenant-Colonel W. Nettle to be Surgeon-Lieutenant Colonel (dated July 3rd, 1906). 19th Middlesex (St. Giles's and St. George's-Bloombury) Volunteer Rifle Corps: Surgeon-Lieutenant W. F. Roe to be Surgeon-Captain (dated March 9th, 1907).

ROYAL ARMY MEDICAL CORPS (VOLUNTEERS).

Scottish Command, Glasgow Companies: Captain D. Christie resigns his commission (dated March 14th, 1907); David Shannon to be Lieutenant (dated March 15th, 1907).

THE REGULATIONS FOR THE EXAMINATION OF CANDIDATES FOR ADMISSION TO THE INDIAN MEDICAL SERVICE.

Revised regulations for the examination of candidates for admission to His Majesty's Indian Medical Service have been issued, one of the principal alterations being a change in the list of subjects under Item 6 which formerly read "Chemistry and Pharmacy, with either Botany or Zoology." It now reads "Materia Medica, Pharmacology, and Toxicology." The maximum number of marks—namely, 600—remains unaltered.

THE COURSE OF INSTRUCTION FOR NAVAL SURGEONS AT HASLAR.

The course of instruction for surgeons of the Royal Navy at Haslar was brought to a close on April 5th, when the

hung his harness. Everything pointed to death from suicide. A witness, however, came forward and offered to narrate the results of some experiments he himself had made. In physical build he was about the same height and weight as the deceased. He stated that he had fixed the bridle and the strap just as it had been placed before the fatal occurrence, he had then walked towards them and just before reaching them he had deliberately stumbled and fallen, so that his neck was caught in the loop; he would have choked had he been unable to regain his balance at once. He repeated this experiment with the same result three times out of four attempts. The court held that this testimony was admissible as showing how death might have occurred.

American Tinned Provisions.

Mr. D. L. Thomas, medical officer of health of the borough of Stepney, in giving evidence at the Thames police court recently in support of a summons for selling unsound condensed milk, informed the magistrate that about 75 per cent. of the tinned foodstuffs imported from America are consigned without labels. This means that whatever information may afterwards be afforded by the label upon the tin is affixed by the firm selling it, with whom it rests whether the statement shall be accurate or not. As an American firm enjoying a high reputation and anxious to maintain it would probably insist upon its distinctive label appearing upon all its goods, the inference would seem to be that a large proportion of the tinned provisions imported from the United States are not of the highest quality, and also it may be conjectured that they are not sold as American products.

Looking Back.

FROM

THE LANCET, SATURDAY, April 11th, 1829.

COMMUNICATION OF HYDROPHOBIA FROM RABID SHEEP TO OTHER ANIMALS.

SOME very interesting experiments have lately been made at the veterinary school at Alfort, with respect to the above subject. Two sheep, belonging to the flock of M. Yoart, having been bitten by a dog, which soon afterwards died with the symptoms of confirmed hydrophobia, and having, about a month afterwards, evinced all the signs of rabies, a horse, a dog, and two sheep, apparently in perfect health, were inoculated with their saliva; the skin was in several places slightly scarified, and the saliva applied to the wounds; at the same time the four animals were left in constant contact with the two rabid sheep, which died on the fourth day after the first symptoms of rabies. A few hours previous to the death of one of them, a dog and a lamb were inoculated with its saliva.

Four months after the experiment, none of the six inoculated animals had exhibited any symptoms of the disease; it is accordingly more than probable, that the disease cannot be communicated from sheep to other animals.

From the description of rabies in sheep, as observed in the above cases, it appears, that it is not accompanied by the dread of water, and that, therefore, in these animals, as well as in dogs, it is improperly called hydrophobia.—*Magendie's Journal.*

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 76 of the largest English towns 8269 births and 5492 deaths were registered during the week ending April 6th. The annual rate of mortality, which had been equal to 16·8 and 17·7 per 1000 in the two preceding weeks, further rose to 17·9 per 1000 during the week under notice. During the 13 weeks ending March 30th the death-rate in these towns averaged 19·0 per 1000, the rate in London during the same period being 19·2 per 1000. The lowest rates last week in the 76 towns were 6·3 in Handsworth (Staffs), 7·0 in Hornsey, 9·1 in Croydon, and 11·1 in East Ham; among the other towns the highest rates were 24·4 in Grimsby, 24·5 in Portsmouth, 24·6 in Birkenhead, 24·9 in Oldham,

and 27·7 in Wigan. The 5492 deaths in the 76 towns showed an excess of 43 over the number in the preceding week, and included 568 which were referred to the principal infectious diseases, against 468 and 559 in the two preceding weeks; of these, 251 resulted from measles, 170 from whooping-cough, 59 from diphtheria, 36 from scarlet fever, 34 from diarrhoea, and 18 from "fever" (principally enteric), but not any from small-pox. No death from any of these epidemic diseases was registered in Bournemouth, Devonport, Wolverhampton, Coventry, York, South Shields, or Tynemouth; the annual rates from these diseases, however, ranged upwards to 5·4 in Hanley, 5·5 in Portsmouth, 7·9 in Birkenhead, 8·5 in St. Helens, and 8·9 in Grimsby. The 251 fatal cases of measles were 18 in excess of the number in the preceding week, the highest annual rates therefrom being 4·1 in West Hartlepool, 4·3 in Portsmouth, 5·1 in St. Helens, 5·2 in Grimsby, and 7·0 in Birkenhead. The 170 deaths referred to whooping-cough showed a decline of five from the number in the preceding week, the rate from this disease, however, ranging upwards to 1·8 in Salford and Preston, 2·1 in Willesden, 2·7 in Bury, and 3·0 in Grimsby. The 59 deaths from diphtheria also showed a further decline from the numbers in recent weeks, the highest proportional mortality being recorded in Sunderland and Gateshead. The fatal cases of scarlet fever, of "fever," and of diarrhoea were not excessive in any of the 76 towns. No case of small-pox has been under treatment in the Metropolitan Asylums Hospitals since the end of June last. The number of scarlet fever patients in these hospitals and in the London Fever Hospital, which in the 14 preceding weeks had uninterruptedly declined from 3846 to 2657, had risen again to 2666 at the end of last week; 352 new cases were admitted during the week, against 327, 312, and 330 in the three preceding weeks. The deaths in London referred to pneumonia and other diseases of the respiratory organs, which had been 403, 353, and 354 in the three preceding weeks, rose again last week to 412 and were 99 in excess of the corrected average number in the corresponding week of the previous five years. The 17 deaths referred to influenza in London were four below the corrected average. The causes of 44, or 0·8 per cent., of the deaths registered during the week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in London, Leeds, West Ham, Newcastle-on-Tyne, Salford, Leicester, and in 47 other of the 76 towns; the proportion of uncertified deaths, however, showed a marked excess in Liverpool Birmingham, Sheffield, Bristol, Bradford, Portsmouth, Reading, and Warrington.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in eight of the principal Scotch towns, which had been equal to 20·6 and 20·3 per 1000 in the two preceding weeks, further declined to 19·4 per 1000 in the week ending April 6th, but was 1·5 per 1000 in excess of the mean rate during the same period in the 76 large English towns. The rates in the eight Scotch towns ranged from 12·9 Paisley and 16·1 in Aberdeen and in Greenock to 21·9 in Glasgow and 24·0 in Perth. The 673 deaths in the eight towns showed a decline of 33 from the number in the preceding week, and included 114 which were referred to the principal epidemic diseases, against 100, 102, and 107 in the three preceding weeks. These 114 deaths were equal to an annual rate of 3·3 per 1000, which exceeded by 1·5 per 1000 the rate from the principal epidemic diseases in the 76 English towns; they included 48 which were referred to "fever," 40 to whooping-cough, 14 to diarrhoea, five to diphtheria, four to scarlet fever, and three to measles. The deaths referred to "fever," which had been 48 and 39 in the two preceding weeks, which had been last week to 48, and included 32 in Glasgow, rose again last week to 48, in Leith, two in Dundee, seven in Edinburgh, six in Leith, two in Dundee, and one in Aberdeen; 29 of these "fever" deaths in Glasgow, six in Edinburgh, five in Leith, and the two in Dundee were certified as cerebro-spinal meningitis. The 40 deaths in the three preceding weeks, increased last week to 40, of which 31 occurred in Glasgow, three in Edinburgh, three in which 31 occurred in Glasgow, three in Edinburgh, and two in Aberdeen. Eight of the 14 deaths from diarrhoea were registered in Glasgow, three in Dundee, and two in Edinburgh. The five fatal cases of diphtheria included four in Glasgow; two of the four deaths from scarlet

having been discovered not generally known to the majority of practitioners which it is desirable should be published for their benefit.

The vast majority of medical men accept the influence of alcohol as a drug, but I believe an increasing number who have given much attention to the subject believe, perhaps wrongly, that its influence in health is always in some degree prejudicial; that the craving for the drug is so easily formed and so powerful when established that it is advisable under all circumstances to confine its action to therapeutic needs only. It should also be remembered that the ordinary medical specialist, unless his practice is confined to alcoholic cases, has less clinical experience than the general medical practitioner, as the latter sees at least as many patients and can study the effects of alcohol by observing altered personal states under the influence of the drug in individuals whom, as the family practitioner, he has known for years.

In common, therefore, with many other medical men I should be glad to know in what respects recent investigations by research students, such as Mott, Ballantyne, Kraepelin, &c., have been modified by still newer work from the following points of view: (a) in relation to experiments (German and American) which seemed to establish the facts that alcohol in quite moderate doses diminishes mental activity; (b) that in physical training it is diminishingly used; (c) that in tropical, arctic, and military expeditions its use as a beverage is being given up; (d) that histological studies, particularly of the nervous system, seem to have proved that its action is deleterious; (e) to show that its resemblance to progressive dementia, in the symptoms that it gives rise to, is not pathological; (f) in view of recent facts discovered in relation to heredity and alcohol to produce convincing evidence to the effect that alcohol does not injure germinal tissue and is not prejudicial to the pregnant and nursing woman; (g) to consider recent insurance statistical evidence which supports the contention that abstainers are long-lived; and (h) to explain why, if alcohol is beneficial in small doses, it has been so largely abandoned in surgery.

I feel sure that many medical men would welcome specific scientific information on each of these points, but opinions without data are justly felt to be valueless and derogatory to medical reputation, if they are not, indeed, morally indefensible.

With many apologies for the length of this letter,

I am, Sirs, yours faithfully,

Willesden Green, N.W., April 5th, 1907. J. LIONEL TAYLER.

To the Editors of THE LANCET.

SIRS.—As you have given publicity to the opinion of 16 medical men upon the value of alcohol in diet and medicine it may interest your readers to peruse certain statements signed by the highest medical authorities of a former generation. In 1839 Mr. Julius Jeffreys, himself a medical man, obtained the signatures of 78 distinguished members of the medical profession to a declaration which is in curious contrast to the statement recently published. The declaration said:—

An opinion handed down from rude and ignorant times, and imbibed by Englishmen from their youth, has become very general, that the habitual use of some portion of alcoholic drink is beneficial to health, and even necessary to those subjected to habitual labour. Anatomy, physiology, and the experience of all ages and countries when properly examined must satisfy every mind well-informed in medical science that the above opinion is altogether erroneous.

Among the 78 signers of this declaration were Sir Benjamin Brodie, Dr. W. F. Chambers, Sir James Clarke, Barnaby Cooper, Sir J. Eyre, Dr. R. Fergusson, Dr. Marshall Hall, Herbert Mayo, Dr. John Hope, O. A. Kaye, Dr. R. Lee, Richard Quain, R. Trevors, and Drs. Andrew and Alexander Ure.

In 1847 a declaration, drawn up by three eminent medical men, ran as follows:—

We, the undersigned, are of opinion 1. That a very large portion of human misery, including poverty, disease, and crime, is induced by the use of alcoholic or fermented liquors as beverages. 2. That the most perfect health is compatible with total abstinence from all intoxicating beverages whatever, in the form of ardent spirits, or as wine, beer, ale, porter, cider, &c., &c. 3. That persons accustomed to such drinks may, with perfect safety, discontinue them entirely, either at once, or gradually after a short time. 4. That total and universal abstinence from alcoholic liquors and beverages of all sorts would greatly contribute to the health, the prosperity, the morality, and the happiness of the human race.

A column of THE LANCET would not contain the names

of the eminent medical men who signed this declaration, which was also subscribed by nearly 2000 medical men in the United Kingdom and India. 60 years have passed since the latest of these declarations was issued, and in that interval comparisons of various kinds have been instituted between moderate drinkers and abstainers as to rates of mortality and sickness; and it may be averred with confidence that all such comparisons have resulted in favour of abstinence and not of moderate drinking. The statement of the 16 medical men is in opposition to all the data which have been accumulating since the origin of the temperance reform, and, in effect, it takes us back to those "rude and ignorant times" in which, according to the declaration of 1839, the opinion of the 16 originated. The former part of their statement deals with the use of alcohol in disease and might have been written had no London Temperance Hospital been at work for 33 years, the experience of which it ignores. That alcohol, like other drugs, may have a use in particular conditions of disease is not denied, but it is impossible reasonably to claim for it the value placed upon it by the 16 advocates in face of the facts—first, that the visiting staff of the London Temperance Hospital, being free to prescribe it when deemed needful, have only done so in the case of 80 patients out of the 26,000 who have passed through the wards of the hospital; and, secondly, that the statistics of the London Temperance Hospital as to the rate of mortality and the proportion of recoveries compare favourably with those of other general hospitals.

I am, Sirs, yours faithfully,

DAWSON BURNS, D.D.,

Honorary Secretary of the London Temperance Hospital.

April 5th, 1907.

To the Editors of THE LANCET.

SIRS.—On March 30th you published a letter signed by a small group of members of the medical profession advising the public (1) to use alcohol as a drug, and (2) all adults (by the way, why not children too?) to usually drink it as an article of daily diet. The gravity of medical men giving such advice in view of the national issues involved cannot, of course, be over-stated, but the responsibility concerns the signatories only; the wisdom of following their advice, however, concerns the public and depends upon the proofs which the signatories rely upon in support of their position. These should be: 1. Experimental. But they offer none; not a single atom of evidence do they give in support of any one of their statements. 2. Statistical. But they are not statistical, for their assertions are directly contradicted by the returns of the Registrar-General and the life assurance societies. 3. Practical. But they cannot be practical, as the diminished mortality of the London hospitals shows, in spite of the enormous reduction in their alcohol bills. 4. Sociological. But they are certainly not sociological, whatever else they may be, as the report of the Physical Deterioration Committee teaches us. 5. Consensus of medical opinion. But the consensus of medical opinion lies precisely the other way, as the petition from over 14,000 of the medical profession in favour of the teaching of hygiene and temperance to the coming generation shows. 6. The support of the "leaders" of the profession; but this they have been unable to obtain, as in spite of widespread and urgent canvassing their letter is signed by only 16 medical men, one of whom has since written to explain that his signature was only secured by a breach of faith. 7. The weight to be attached to the names of the signatories themselves. As this personal factor is unfortunately the only guarantee they offer for their advice, it must, however reluctantly, be carefully analysed. Perhaps the least objectionable manner in which this point may be approached is to show what qualifications the names ought to possess in order to give them the necessary weight in the balance. First, being so few in number they should, without exception, be members of the front rank of the profession who are actively engaged in scientific or literary research into all aspects of the alcohol question; second, they should show in these days of "brewery shares" that they are peculiarly disinterested in the question; and thirdly, they should be able to demonstrate that there is no risk of a "moderate" use of alcoholic beverages (by the way, what quantity is "moderate"?) ever leading to the habit of incipient intoxication. Until they offer proofs in satisfaction of the foregoing points it would certainly appear that the only common-sense course for the lay public to adopt is to regard (or rather

prizes were distributed. The gold medal was awarded to Surgeon W. H. Hastings of University College, the microscope to Surgeon S. F. Dudley of St. Thomas's Hospital, and the silver medal and books to Surgeon J. L. Barford of King's College. The names of the candidates, two of whom had university degrees, with the marks gained at the entrance examination and at the Haslar course, are subjoined:—

	Marks.		Marks.
W. H. Hastings	4660	W. W. D. Chilcott	3395
S. F. Dudley	4485	J. O. F. D. Vaughan	3792
J. L. Barford	4341	W. F. Archibald	3535

NAVAL MEDICAL SUPPLEMENTAL FUND.

At the quarterly meeting of the directors of the Naval Medical Supplemental Fund, held on April 9th, with Mr. O. I. Thomas, O.B., Secretary of the Admiralty, in the chair, the sum of £75 was distributed among the several applicants. Mr. G. W. Perrin was appointed secretary to the fund, vice Mr. P. Francis resigned.

THE INSPECTOR OF MEDICAL SERVICES.

The April Army Orders, issued by command of the Army Council, contain the following:—

75. *King's Regulations (Amendments).*—The following new paras. will be inserted after para. 183b:—

The Inspector of Medical Services.

183c. The Inspector of Medical Services will report on:—(a) The physical and sanitary efficiency of the forces, and on any precautionary or remedial measures relating to barracks, encampments, garrisons, stations, hospitals, diet, dress, drills, duties, &c., which may, in his opinion, conduce to the preservation of the health of the troops and the mitigation or prevention of disease. (b) The medical examination and physical training of recruits, both at depôts and with units, and whether the gymnasium courses, drills, duties, &c., subject the men to undue strain. (c) The methods of medical administration in districts and commands, with a view to establishing a uniform system throughout the army. He will also inspect military hospitals and visit transports and hospital ships.

183d. He will report on the adequacy of the sanitary instruction afforded to the army, and also on schools of instruction (including garrison schools) and courses of instruction conducted by the R.A.M.C.

183e. He will inspect the R.A.M.C. and general medical stores (including the store at Woolwich) and will report whether all ranks are thoroughly acquainted with their duties in connexion with the medical arrangements for mobilisation.

THE NATIONAL SERVICE LEAGUE AND THE TERRITORIAL ARMY SCHEME.

The letter which the National Service League has addressed to the press is a very notable document from whatever point of view it is considered, whether as regards the eminence and authority of the names attached to it, the argumentative strength and reasonableness of the criticism it brings to bear upon Mr. Haldane's new army scheme, or the fairness and common sense with which the subject is handled. To those who know from personal experience what war is, whether serving in the combatant ranks of the army or in the Royal Army Medical Corps, there is no need for us to say anything, for they have no doubt already made up their mind on the matter. But we strongly commend this publication on the part of the National Service League to the earnest and thoughtful consideration of all desirous of forming some opinion of the merits and defects of Mr. Haldane's scheme and of finding their way to some reasonable solution of the army problem. To confine ourselves to one point only because it seems to us a crucial one for the successful working of Mr. Haldane's scheme—will it include a compulsory six months' preliminary training or not? We shall no doubt know much more about the intentions of the Government at the end of the second reading of the Territorial and Reserve Forces Bill than we do now. As to a system of universal compulsory training leading to a widespread spirit of militarism, we believe that it would have an exactly opposite effect. National preparedness for war should, by increasing national confidence and a sense of personal responsibility, strongly strengthen the chances of peace and lessen the liability to unseemly panic. Even apart from its being the reasonable duty of every citizen to aid in the defence of his country, we contend from our point of view that an obligatory military training increases the physical strength, improves the physique, and teaches a man how to conduct himself, mentally and morally, to the best advantage in all emergencies.

THE CAPE PREMIER AND IMPERIAL DEFENCE.

The Colonial Conference will be long be setting about its deliberations, which will be of an Imperial character, and Dr. Jameson, the Cape Premier, will, it is announced, submit two propositions for consideration, one dealing with

the creation of an Imperial Council and the other with the subject of British preference. We call attention to the former because it seems, at the present time, to open a way to the possible unification of the Colonial forces available for Imperial defence on a large scale, when the provision of an Imperial Medical Service available for any future war would necessarily form an integral part of the organisation. Dr. Jameson's proposed resolution is to the following effect:—

This conference considers necessary the organisation of a plan of Imperial defence by which the contributions of each colony should be equitably fixed and provided for; this conference believes that while any call to arms resulting from an attack on the Empire would unquestionably meet with an enthusiastic response from the colonies, yet it is essential to know the number of trained, equipped, and efficient men which the colonies will undertake to make available for Imperial defence when called upon; this conference, however, is of opinion that, prior to accepting the burden and expense of such a responsibility the colonies would require to be represented on an Imperial Council at which questions concerning *inter alia* the peace of the Empire should be discussed. Seeing that the above resolutions involve considerations of the first importance to the future of the Empire, this conference submits them to His Majesty's Government in the confident belief that they will receive the serious consideration which their character demands.

Correspondence.

"Audi alteram partem."

THE MEDICAL DEGREES OF THE UNIVERSITY OF LONDON.

To the Editors of THE LANCET.

SIRS,—In reference to the present controversy concerning the maintenance of the standard for the above degrees, I have been asked, on the ground that I was an examiner in medicine during the last year of the old system as well as during the first three years of the new, whether there has or has not been any actual lowering of the standard. May I be permitted to say that I have throughout considered it my duty to maintain the standard, and that to the best of my knowledge no lowering has taken place. So far as the medicine at the M.B., B.S., is concerned, my impression is that at the present time the standard is higher than at any previous period. Of this I am certain, that no suggestion—official or unofficial—to the effect that at any of the examinations in which I was concerned any lowering of the standard was advisable has ever reached me or been discussed in my presence, and that ancient usage has been the principal factor in solving new problems.

I have assumed, how far correctly I cannot say, that the improved results at the M.D. examination have been due to two changes. Under the old scale of fees a candidate paid £5 on entering for any M.D. examination. Under the recent scale he paid £20 instead of £5 on first presenting himself, and, if he failed to pass, an additional £20, instead of £5, every time he re-entered. It appears highly probable that a graduate would, under the higher scale of fees, be more careful in preparing himself for the examination and be less likely to enter unless he felt tolerably certain of passing. Again, the additional opportunities for specialisation under the new regulations afford a man a chance of working at what most interests him, and therefore of attaining more easily a higher degree of knowledge.

It is the business of examiners to test as closely as possible the merits of the individual candidates and to arrive at a decision without reference to the statistics of previous examinations. Any other course involves gross injustice to the candidates, and must bring discredit upon the University.

I am, Sirs, yours faithfully,
H. MONTAGUE MURRAY.

London, W., April 9th, 1907.

THE USE OF ALCOHOLIC BEVERAGES.

To the Editors of THE LANCET.

SIRS,—As a member of the medical profession, who has practised for some years in a district where the effects of alcohol can be readily studied, I may be permitted to ask, in view of statements—so much at variance with recent investigations—made in the manifesto in THE LANCET of March 30th, gations—made in the manifesto in THE LANCET of March 30th, for evidence by which the old conclusions have been re-affirmed. Such statements, which may, and probably will, exercise an extremely harmful influence on the community at large, can hardly have been made public without fresh data

A.C. under "normal" do not pretend to represent accurate measurements of B.C. and A.C.

I am, Sirs, yours faithfully,

D. MATHESON MACKAY, M.D. Edin.,
Late Senior Clinical Assistant, Hospital for Diseases
of the Throat, Golden-square, London, W.

Hall, March 22nd, 1907.

THE INCREASE OF INSANITY.

To the Editors of THE LANCET.

SIRS,—I greatly regret that I should have caused annoyance to Dr. Marr by my suggestion that the difference between the increase among general paralytics in Glasgow and in Edinburgh might be the result of better clinical observation in the latter. For this suggestion I have no ground, but still it is a very difficult thing to believe that it is a fact that the disease increases more in Edinburgh than in Glasgow, and I ought to have put it that it probably was a question of difference of diagnosis. Any way I am certain that the careful examination of patients at Woodilee leaves nothing to be desired.

Yours truly,

Devonshire-place, W., April 9th, 1907.

GEO. H. SAVAGE.

A NATIONAL SCHOOL FOR CONSUMPTIVES.

To the Editors of THE LANCET.

SIRS,—My attention having been called to a letter by my friend, Dr. M. S. Paterson, of the Frimley Sanatorium, in your issue of March 23rd, *apropos* of an article by Mr. C. H. Garland and myself under the above title, may I be allowed to correct what seems to be a misconception when he infers that our views were based on our visits to Frimley? Our scheme was framed originally in 1903 and 1904 and in the inclosed copy of my interim report as chairman of the Sites and Buildings Subcommittee (p. 7, Fourthly) printed for March 11th, 1904, you will find that our advocacy of the adoption of the system of employing selected patients in sanatoriums—which, by the way, is no new thing—antedated not only our visits to the Brompton Hospital Sanatorium by a few years but also, I believe, the erection and opening and Dr. Paterson's appointment thereto.

The scheme of the National Association for Establishing and Maintaining Sanatoria, for which I have had the honour and pleasure of working continuously since its inception, has been developed almost without modification on the lines laid down in the report quoted. The other medical members referred to therein were Dr. A. P. Hillier and Mrs. Percy Alden, who were both unfortunately obliged to give up this work by other public calls upon them, but not before giving very substantial assistance. Dr. Paterson has achieved a striking piece of organisation and administration, and no one engaged on the development of similar methods on a large scale in England can afford to ignore his demonstration of the possibilities of this work. I wish to take this opportunity, in case our article did not convey our gratitude as sufficiently as it might have done, of thanking Dr. Paterson and his colleagues for enabling Mr. Garland and myself, as well as Dr. L. Crossley, the medical superintendent of our first sanatorium at Benenden, to see what was being done at Frimley.

I am, Sirs, yours faithfully,

Brook-street, W., April 2nd, 1907.

THOS. D. LISTER.

SANITARY ADMINISTRATION IN PAIGNTON.

To the Editors of THE LANCET.

SIRS,—I have had a copy of your editorial note under the above heading sent to me, and as a resident in Paignton for the past 18 years and recently a member of the urban district council I wish to reply to some points upon which I venture to think you have been misled by the report of the medical officer of health, who has evidently overlooked the fact that the report may come into the hands of those who have no local knowledge.

I will take the case of the supposed disregard of the by-laws, where it is said that the council is permitting a road 600 feet long to be only 24 feet wide. The report does not state that this is a parish road leading from Paignton to Meldon and having an average width of 13 feet. All the council could compel the adjoining owners to do in the event of houses being erected would be to keep the frontages back 18 feet from the centre of the road. An owner has offered to give a strip of land which would enable

the road to be made 24 feet wide to form a footpath with curb and channel if the council will lay the sewer and ballast and form the new piece of road. The question whether this was a new road within the meaning of the Private Street Works Act was raised at the Local Government Board inquiry and disregarded by the inspector, and the sanction for the loan has been received. The new water scheme referred to by you is an auxiliary scheme for distributing the water to the higher levels of the town. The main water scheme is finished, and the water which has been brought 18 miles from the centre of the moor is now running into the home reservoirs, and the formal opening is fixed for June. The total cost of this portion of the scheme is £120,000, and both Teignmouth and Brixham will be supplied from Paignton. The dispute as to the relative values of the three schemes submitted to the council is purely an engineering question and cannot affect the health of the town in any shape or form, but the fact that the council has decided to leave it in the hands of the engineer, who is responsible for and has carried out the main scheme, would seem to be the right course to have taken.

I consider the statement of your local critic as to illness in the town over-coloured and made upon hearsay evidence. My own son is one of those who are at present suffering from scarlet fever, and the most careful research fails to show how it was contracted or any connexion with the few other cases in Paignton. The question of an additional ward at the hospital should be considered to overcome any future difficulty caused by the wards being occupied by enteric cases, but I believe the fact that the hospital is empty for months at a time could easily be proved. Your correspondent has omitted to point out that last summer a large sum was spent on the outfall of the sewer, that a break was located and mended, and the sewer was carried 250 feet farther out to sea. With regard to the water, I can only say that I have never had to boil it and my Pasteur filter shows no trace or indication of any organic matter being contained in the water.

With regard to the infantile death-rate, it should be considered that the wealthy class in Paignton are largely people who come here after retiring from the army, navy, or business, and are therefore for the most part past middle life. It follows that by far the larger number of births are among the artisans and labouring classes amongst whom the rate is always high.

I am, Sirs, yours faithfully,

Paignton, April 4th, 1907.

W. PIERPOINT ROBERTS.

EIGHTH INTERNATIONAL CONFERENCE OF RED CROSS SOCIETIES.

To the Editors of THE LANCET.

SIRS,—I have seen in THE LANCET of March 23rd an article on the subject of the forthcoming International Red Cross Conference. The statements it contains require correction. In regard to no official intimation of the conference having been given, an official notice was sent to you and was published in THE LANCET on Feb. 16th. It was also extensively circulated throughout the press of the country. I inclose a fresh copy of this notice which fully states who are responsible for the arrangements and where the meetings will be held. Further than this, you had on Feb. 2nd already published an article giving the same information, and in regard to the exhibition we advertised it in THE LANCET of, I believe, Feb. 8th.

I may add that all the Central Red Cross Societies who are entitled to send delegates to the Conference have been made fully acquainted with the manner in which it has to be conducted, that having been prescribed at the last conference at St. Petersburg in 1902.

In reference to your general remarks about this society perhaps you will allow me to send the inclosed pamphlet which explains its scope and origin. I shall have much pleasure at any time in providing you with the fullest information should you give me the opportunity, and I think you will find that the Conference will be conducted in every way in a manner worthy of the occasion.

Believe me, yours faithfully,

(Signed) J. DANVERS POWER,

Chairman, Conference Committee.

British Red Cross Society, 9, Victoria Street, London, S.W.,
March 27th, 1907.

* * We regret to have been misled with regard to the steps taken by the Red Cross Society for giving publicity to the Conference of 1907. We refer our readers to an editorial article in THE LANCET of Feb. 2nd, p. 311.—Ed. L.

disregard) their "pronouncement" as being a negligible quantity.

I beg to subscribe myself
A MEMBER OF THAT PUBLIC FOR WHOM THE
April 6th, 1907. PRONOUNCEMENT WAS INTENDED.

** We have received very many letters on this subject and shall possibly publish a further selection of them. We are glad to notice in communications from most of our medical correspondents the absence of the suggestion that political or pecuniary motives induced the publication of the much-discussed document.—ED. L.

ON THE CONDITION OF THE BLOOD-VESSELS DURING SHOCK.

To the Editors of THE LANCET.

SIRS,—Though not acquainted with surgical shock I feel greatly interested in the discussion on the above-mentioned subject. It proves so very clearly how ignorant we are of this difficult and intricate problem of the blood pressure in man. So far, indeed, goes our ignorance that two so widely different opinions are possible about a so marked disturbance of circulation. I cannot confirm Mr. Malcolm's views on shock but have to confess that I am much impressed by his arguments. I think his way of looking at the vessels, as described in his lecture in THE LANCET of August 26th, 1905, p. 573, may be very helpful in detecting the true state of things in many a case. Some time ago I was asked to see a woman aged about 40 years. It was a case of long-standing mitral stenosis. The right heart was still strong enough, the muscular apparatus at the orifices of the veins still working well; there was no general stasis or cedema but this sad condition of overfilling of the lungs which suffocates the patient. She was in the very last period of her disease and died a few weeks afterwards. Still, to save, or at least to prolong, life the doctor prescribed digitalis; not seeing any effect he gave it in a very large dose as an enema. To his great surprise he saw the (still regular) pulse disappearing and asked me to come over and see the patient. I found a filiform, nearly impalpable pulse, but very strong heart sounds and apex beat. Looking at the neck of the patient to see whether there was any venous pulsation I found well-filled, extremely hard, and wildly beating throbbing carotids. It was obvious that the heart was working against a heavy resistance. Why was the pulse so impalpable?

The explanation is, I think, in the line of Mr. Malcolm's suggestions. The large dose of digitalis contracted the arteries higher up than the radials at the wrist, the carotids being not, or not so much, contracted. The heart therefore worked against a heavy resistance, there was a very high intracardial pressure and a high blood pressure in the carotids. Now who will tell what the blood pressure has to be in the contracted radials at the wrists? Is Dr. Williams sure that it will be found high in that part of the arterial system? The problem of blood pressure is not settled by saying "if the blood-vessels contract the blood pressure rises; if they dilate the blood pressure falls." This assertion holds good for the intracardial pressure only. At the periphery it depends upon the spot where blood pressure is gauged and upon how far the contraction of the vessels has gone. I think it very probable that under some extraordinary influence (maybe in shock) the contraction of the vessels may go up still higher than the arteries in the arms and involve carotids and part of the aorta. The intracardial pressure may rise enormously and a low pressure be found in the periphery, where a large amount of resistance has been overcome. So I do not say Mr. Malcolm's explanation of surgical shock is the right one, but I think it may be useful in clinical examination and may be a help in explaining conditions which otherwise are not well understood.

I am, Sirs, yours faithfully,

Groningen, March 31st, 1907.

K. Z. WENCKESACS.

To the Editors of THE LANCET.

SIRS,—In my letter on this subject which you were good enough to publish on March 23rd, I invited Mr. J. D. Malcolm to point out the existence of any fallacy in one of the arguments by which the present view is supported. He responds in your issue of March 30th with two statements, one of

which, even if it be a fact, is not a fallacy, and the other of which is certainly neither fallacy nor fact.

The first is that in shock the blood pressure in the splenic vein is raised. Now, the splenic vein is a vessel which, owing to its anatomical position, does not lend itself either to frequent observations or to such as are altogether free from sources of error; but even if this were otherwise, from the interposition of the heart on the one hand, and the capillaries on the other, it must be obvious that the state of the pressure in an individual vein has no necessary or even probable relation with the general state of the pressure in the arterial system. The second statement is that a fall of blood pressure as recorded by the manometer might be due to a vaso-dilatation which is local and not general. Unfortunately for Mr. Malcolm, this is not so. The healthy organism must not, and will not, allow the blood pressure to fall below the normal level. If it does, the medulla is immediately threatened with starvation and the animal with death. A local dilatation is therefore immediately compensated for by a constriction elsewhere, so that the pressure may be maintained at its proper level. When, therefore, a local dilatation causes a fall in blood pressure it means that there has been no compensatory constriction elsewhere. This can only occur when the constrictor power is seriously impaired, as, for example, when the medulla is exhausted. There is thus no escape from the conclusion that, the cardiac power being constant, a low blood pressure indicates a general vaso-dilatation.

The contention that the condition of shock can be characterised by an unimpaired cardiac power, together with a general vaso-constriction, surely reveals some confusion of thought. Such a combination is very suggestive of a ruptured blood-vessel, but, except by a hemorrhagic route, it seems impossible to understand how it can cause the extreme degree of asthenia which is generally understood by shock.

I am, Sirs, yours faithfully,

London, W., March 30th, 1907.

LEONARD WILLIAMS.

"A PRELIMINARY NOTE ON RINNÉ'S TEST."

To the Editors of THE LANCET.

SIRS,—I hope I shall not seem to be displaying undue haste if I venture to make a suggestion to Mr. Richard Lake in connexion with his "Preliminary Note on Rinné's Test" in THE LANCET of Feb. 23rd, p. 505. I might wait to see the detailed statement which he promises and which I am looking forward to, but then my suggestion might be too late.

If I may be allowed to say it, Mr. Lake's method of recording the subdivisions of Rinné's test seems to me to be lacking in point. The method is accurate, of course, but the idea of each subdivision is grasped only after a more or less lengthy mental effort. Why not use the diagrammatic representation which is in vogue in Professor Politzer's clinic? The positive or negative quality is seen at a glance, and not only can Mr. Lake's six subdivisions be shown but any number of variations in them. Two vertical lines stand for the relative lengths of B.C. and A.C., and as, in the normal state of hearing, the length of B.C. is less than that of A.C., the line standing for the B.C. of normal hearing will be shorter than that standing for A.C. The following seven diagrams, therefore, will indicate normal hearing, and the six subdivisions referred to in Mr. Lake's paper.

The inclination of the line connecting the bases of the two vertical lines at once shows whether the positive or negative quality obtains. I need hardly say that the lines B.C. and

much useful work for the benefit of the school children. Former donations and economies have been invested, and altogether they yield to this local school fund interest to the amount of 3700 francs annually. Then there is a subvention from the general council of the department of the Seine of 2400 francs and other very small items. The greatest of all sources of revenue is 21,000 francs derived from the letting of spaces in the streets to stall-keepers and showmen during local fairs. It has been pointed out that this is injurious to public health, for the streets or open spaces are overcrowded and cannot be kept so clean while these fairs last. Also the stalls injure the business of the neighbouring shop-keepers. The fairs, however, are still held because they amuse some people; but, above all, because the receipts derived therefrom are devoted to the school funds. Thus, in the XIV. arrondissement the total receipts from all sources for the school fund amounted in 1906 to 32,160 francs (£1286), of which sum 21,000 francs (£840) were derived from the rent charged to showmen, and there were subventions amounting to another 2650 francs, or £106. Deducting from the total receipts of £1286 the £143 interest paid on invested capital as being difficult to define, I will deal with the remaining £1136. Of this £546 come from one form or another of taxation and only £153 from voluntary subscriptions or donations. Smaller receipts, such as £24 paid by parents whose children joined the holiday excursion and the interest on invested capital, make up the total income of 32,160 francs, or £1286.

It will illustrate the working of the system and show what is the real function of these local school funds to mention how this money is spent. The largest item is 8500 francs spent in buying boots for the more needy school children. The money laid out on clothes, to a large extent pinafiores, was not so considerable—namely, 5000 francs. In the budget of the XVII. arrondissement, or the Batignolles-Monceaux district, I find that 12,877 francs were spent on boots and only 4931 francs on clothes. Then in the XIV. arrondissement 2400 francs are entered as rewards to pupils, medals and other gifts, but for the most part these rewards took the form of opening accounts for the children in the savings bank, thus giving an object lesson in thrift. Honorariums to secretaries, &c., amounted to 2100 francs, the prizes given to the children for July 14th historical competition 600 francs, and printing, stationery, and small items brought up the total expenditure to 23,140 francs; thus a balance of 10,020 francs remained in hand. It was out of this balance that 5000 francs were given to the *cantines scolaires*. It will be seen that the bulk of the expenditure is outside of the school fund or *caisse scolaire*. This "outside budget," as it is called in the annual report of the *caisse des écoles*, is set forth as follows: maternal schools for children from three to six years of age, interest on invested money, £4; municipal subvention, £136; total receipts and total expenditure, £140. *Cantines scolaires*: subvention from the municipality, £3200; contribution from the local *caisse des écoles*, £200; total receipts and expenditure for the feeding of the children in the elementary schools of the XIV. arrondissement, £3400. The school colonies or *colonies scolaires*, formed to enable weakly children to spend some time at the seaside or in the country, cost £560, but the municipality only gave a subvention of £360. The deficit of £200 was met by a contribution of that amount from the *caisse des écoles* and taken out of their £400 surplus. This is an illustration of the very general principle that feeding being the first of necessities the municipality gives by far the largest subvention for this purpose. The sending of children for health holidays in the country was left more to local effort and hence, as in this instance, the *caisse des écoles* contributed a much larger share of the expense. In the XVII. arrondissement the municipal subvention during the year 1905 for the holiday health excursions was £400 and the contribution from the local school fund £224. For the canteens the municipal subvention was 60,283 francs (£2411). The payments for meals by the parents amounted to 17,277 francs (£691). The total outlay was 94,501 francs (£3780). There was a very big deficit and the local school fund advanced £551 to balance the accounts. It may be of interest to note that out of this total of £3780 the food cost £2850 and the fuel £199, the rest being spent in furniture, utensils, cost of management, wages to servants, &c.

From the details given of these two local budgets it would seem that the contributions of the local school funds exceed 2 per cent. of the expenditure. Doubtless M. Hénaffe got

his figures from the handsome volume published in 1900 on the occasion of the Universal Exhibition by the Paris municipal council describing all the educational services. Here, on page 171, there are some very interesting figures for nine years. From this statement it appears that in 1891 the municipality contributed 639,635 francs to the *cantines scolaires* and the *caisses scolaires* of the 20 arrondissements only gave 7540 francs. In 1894, however, they gave 36,472 francs and the municipality 787,660 francs. From that year the contribution from the school funds to the canteens decreased and that of the municipality increased till, in 1899, the school funds only gave 21,600 francs, but the municipality gave 1,017,695 francs; and in these latter figures we get the proportion of 2 per cent. mentioned in M. Hénaffe's report. During the nine years in question, 1891 to 1899 inclusive, the total amount contributed by the *caisses des écoles* towards the expenses of the *cantines scolaires* was 192,295 francs (£7691) and by the municipality 7,418,171 francs (£296,726).

On page 176 of the same official volume there is another important table. It compares for each arrondissement the number of pupils during the years 1892 and 1893, the number of meals they paid for, the number of meals they received gratuitously, and the average cost per meal. From this it appears that in 1892 the number of gratuitous meals was equal to 56 11 per cent. of the whole and in 1893 it was equal to 63·93 per cent. of the whole. To-day we have seen that it is a full two-thirds of the total. It is also shown that the meals to-day cost more than they used to do, for the average cost in 1892 is set down at 0·14638 franc per meal and 0·14843 franc in 1893, whereas to-day it is 0·171 franc. The tendency is to improve the meals, to give more meat, sometimes as much as 30 to 40 grammes, and thus more money is spent. This improvement will certainly increase as a higher class of children frequent the canteens and the impression gains ground that money can scarcely be better spent than in insuring the physical health and strength of the nation.

All these figures and calculations will, I trust, make the practical teaching of the Paris experience clear. The municipal councillors and others, whom I have recently seen at the Hôtel de Ville, entertain very little doubt as to the likely upshot. It is evident that only a third of the parents pay and then they do not pay the full cost of the meals their children eat. So that all the children and all the parents derive some advantage at the cost of the general ratepayer. When attempts are made to get more voluntary subscriptions for the school funds the persons solicited very often answer that they pay such heavy taxes that there should be no need to add to these any further sum. Not a few of the parents also, when it is pointed out to them that they should endeavour to pay for the meals given to their children at school, object that they are already paying through taxation, and this is perfectly true. Thus the number of those who individually pay for the meals have steadily decreased from year to year and it is already an open question whether the money thus obtained is worth the trouble of collecting. Its collection causes friction, creates invidious distinctions between individuals, gives rise to accusations or the suspicions of favouritism, necessitates somewhat inquisitorial investigations into the private concerns of numerous families to ascertain who should and who should not pay, and occupies a large staff of persons on an unpleasant and unproductive investigation. Then why should a workman who is just a little better off than his neighbour, because, for instance, though earning the same wage he has two children instead of three, be made to pay twice over for his children's meal, once to the *caisse scolaire* of his district and once to the rate collector? The section of the population that can and does pay for their children's meals are beginning to realise that it would be very much to their advantage if the entire cost was defrayed out of public funds. For instance, the canteens cost rather more than £60,000 a year and a third of the parents pay rather less than a third of this sum directly to the schools but they also pay their share of the £40,000 municipal subvention. It would evidently be cheaper to pay only a slight increase in municipal taxation.

The old argument that the free feeding of the children would weaken parental responsibility has quite died out in France, where every adult male has a vote and all pay the municipal taxes. Parents exercise their sense of responsibility by voting as intelligently as possible in their children's interest. As a consequence, not only is the municipality

THE FREE FEEDING OF THE PARIS SCHOOL CHILDREN.

(FROM OUR SPECIAL SANITARY COMMISSIONER.)

THE RESPECTIVE ATTRIBUTES OF THE CAISSES DES ÉCOLES AND THE CANTINES SCOLAIRES.—THE AVERAGE COST OF THE MEALS.—THE ELIMINATION OF CHARITY.—THE GIGANTIC SCOPE OF THE EXPERIMENT.

TWO years and a half have elapsed since last I visited and wrote about the free feeding of the children in the elementary schools of Paris.¹ In the interval Mr. Birrell, as Minister of Education, stated in the House of Commons that the local authority in Paris provided food for the school children and that "it worked exceedingly well. The advantage of such a system," he went on to say, "was that the people raised their own standard of living very much and created in their stomachs a divine satisfaction. They could confer no greater service upon posterity than raising the standard of living of the children. If a child had good and nutritious food he or she would take care to see that in turn their children had good food also. He should be sorry to forbid by law a local authority from trying experiments upon a large scale, whether they were confined to the necessitous poor or not. It is done in Paris, and if it could be done there they in London should be able to do it also. In Paris ten and a half million meals were served last year, and, although it was difficult to ascertain what proportion of them were free, there was reason to believe that a very large proportion of them were given in exchange for payment." Mr. Birrell is not alone in failing to understand clearly the financial position of the Parisian *cantines scolaires*. Indeed, they have been confused with the *caisses des écoles* to such a point as utterly to misrepresent this important institution. What Mr. Birrell himself would consider a very large proportion of payments it is difficult to say, but I will give the actual figures and then it is probable many persons will, on the contrary, find that the proportion of payments is small.

A very instructive "Note relative au Service de Garde des Cantines Scolaires" was presented to the Paris Municipal Council by Councillor Hénaffé and was issued in February, 1907, as paper No. 11 of the official publications of the council. This document sets forth that in 1905 6,144,634 meals were served gratuitously and 3,184,669 in exchange for payments. Thus, at once, it is obvious that only one-third of the meals were paid for by the children or their parents. If, however, the details are studied it becomes evident that the proportion of payment is less. These details are interesting in themselves and apart from the question as to who pays. It will be remembered, as I described in my first report on the subject, that during the earlier experiments made at Paris the cost of the meals amounted to 25 centimes, or 2½d., each. It was only after the acquirement of great skill and experience in cooking and in the management of the canteens that the cost was reduced to 1½d., and this on condition that not more than from 20 to 25 grammes of meat, cooked and free from bone, was given. Now, for the year 1905 the average cost of the meals amounted to 0.171 franc each, or within a minute fraction of seven farthings each and a little more than two centimes above the usual estimate of 15 centimes or six farthings. But if the cost exceeded the estimate the payments were below. It is here that the part played by the administration of the *caisses des écoles* bears upon the subject. Paris is divided into 20 submunicipal districts called "arrondissements." Each has its *caisse scolaire*, and where the parents are called upon to pay for their children's meals the charge made by the *caisses scolaires* varies considerably. The maximum payments effected amounted to an average of 18 centimes in the fourth and to 17 centimes in the twelfth arrondissements. In the second, third, seventh, tenth, eighteenth, and twentieth the traditional average of 15 centimes was paid. In the remaining 12 arrondissements the average came to less than 15 centimes. In five districts it amounted to only ten centimes per meal. The average for all the 20 districts, including the fourth, where parents distinguished themselves by paying nine-tenths of a centime more than the actual cost, amounts to 0.138 franc. Thus, even where payment is effected, the sum given is on an average only about five and a half farthings out of

the seven farthings spent, and this, I take it, refers to the food actually consumed. In any case, the material, the kitchen utensils, the plates, and the rent of the localities occupied are not included in this estimate of the cost of the meals. The total loss on the food consumed in the 20 districts by the children, for whose meals payments have been made by the parents, is put down for the year 1905 at 114,492 francs, or £4579. If to the actual cost of the food the other attendant expenses are added, it may be speaking in round figures, that two-thirds of the children do not pay for their meals and that the remaining third receive from the public purse an annual subvention of close upon £5000 towards the cost of those meals for which they do effect payments.

M. Pierre Morel, municipal councillor, in his report on the *cantines scolaires* published in 1905, No. 60 of the official publications, gives the figures for the previous year and they are very similar. Thus, in 1904, the free meal given amounted to 5,975,359, while those for which payments were made equalled 3,253,919, making a grand total of 9,229,278 meals. If we multiply this latter figure by 0.171 franc, the estimated average cost of each meal, we get the total of 1,578,004 francs, or £60,320. As the municipal subvention amounted to £40,800, it will be seen that here again the parents paid, roughly speaking, about a third of the total cost.

It has been said, however, that the cost of feeding the children was in a measure defrayed by the *caisses des écoles*. Then, as these school funds were originally provided by voluntary contributions, attempts have been made to infer that the feeding of the children in Paris was to a considerable extent the result of charity. Whatever opinion may be held as to what should or should not be done, nothing but mischief can result from a misrepresentation of facts, especially when, as in this case, they refer to the largest experiment that has been made in Europe. As already explained, the law of April 10th, 1867, distinctly states that the *caisses des écoles* will "consist of voluntary subscriptions, of subventions given by the commune, by the department, or by the State." At first voluntary subscriptions did constitute an important part of the receipts, but then the feeding of the children was not attempted. In the official "Note" mentioned above and written by the municipal councillor, M. Hénaffé, there occurs the following important passage:—

If the figures given of the actual working of the *cantines scolaires* are compared, it will be seen that nearly all the *caisses des écoles* charge less for meals than they cost. This fact is explained by the willingness of the town of Paris to pay the difference and the large part it plays in assuring the existence of the *cantines scolaires*. You know that the *caisses des écoles* contribute towards these expenses only an insignificant sum, while the sacrifices made by the town of Paris are enormous, since its share in the expense of the canteens amounts to about 98 per cent. of the total.

This is a statement which may be challenged, not in regard to the principle involved but because certainly in many districts the contribution of the local *caisses des écoles* occasionally amounts to more than 2 per cent. of the cost of the canteen. It is very difficult to make accurate comparisons, as the different districts have different methods of keeping their accounts and charge different prices for the meals they give. A unification of methods is much needed. As an illustration, however, of the objection to the 2 per cent. estimate I find that the *cantines scolaires* of the XIV. arrondissement, or district of the Observatory, cost for the year 1906 the sum of 85,000 francs, and the receipts consisted of a municipal subvention of 80,000 francs and a donation from the *caisse des écoles* of that district of 5000 francs. This latter sum obviously represents a great deal more than 2 per cent. of the total cost of feeding. But, on the other hand, it does not mean that these 5000 francs were derived from charity.

The charitable contribution towards the feeding of the children is much less than 2 per cent. of the whole cost. As the *caisse des écoles* of the XIV. arrondissement contributes a comparatively large sum, I will take it as an example of the working of the system. The local budget of this school fund for 1906 shows that the annual subscriptions are estimated at 3500 francs, and there are donations, often from wedding parties, to the amount of 450 francs, making a total of £158. But the annual subscriptions, generally of 10 francs, or 8s., per subscriber, are given not so much as a charitable financial help—the real object is to secure the right to vote for the election of the committee of management which does so

the whole of Scotland, extending even to the outer Hebrides and the remote parts of Caithness, Sutherland, Inverness, and Argyll. In connexion with these classes the association has issued more than 72,000 certificates of proficiency in first-aid to the injured, over 20,000 medallions for advanced students in first-aid, and nearly 2000 certificates of proficiency in home nursing and hygiene. Throughout Scotland 42 centres of the Association have been established, and a service of ambulance wagons has been provided in every considerable town in which a police ambulance service does not exist. In Glasgow, for example, the whole ambulance work of the city and neighbouring burghs is done solely by the wagons of the Association, and it is believed by us in Scotland that no finer ambulance service exists in any part of the United Kingdom. The calls attended to by the association's motor and other ambulance wagons in Glasgow alone amount to 12·44 daily. The association has further trained the constabulary throughout Scotland in giving first-aid, so that there are now few places in Scotland where this cannot be obtained from the police. During the late South African war the Association equipped and sent out a base hospital of 520 beds, and it is now recognised by the army and navy as an institution with which these authorities can enter into direct relations for the supply of men and material in case of emergency. In addition the association has recently been intrusted by the British Red Cross Society with the organisation of its work in Scotland. As the Association has for so many years done such excellent work and appears to be capable of efficiently meeting all requirements, it seems only reasonable to ask that the Order of St. John should not be allowed to initiate new centres of ambulance work in Scotland, and thus engender rivalry and competition which could not but be detrimental to the interests of ambulance work in general. Those who control the affairs of the Order of St. John are of opinion that the St. Andrew's Ambulance Association should become merged in the Order as a department charged with ambulance work in Scotland. This view the Association refuses to accept as being in derogation of its charter, and likely to cripple seriously the work it has carried on so successfully for 24 years. But the Association has gone so far as to offer to act as the Order's ambulance department in Scotland, it being understood that by so doing the charter of the Association would not be invalidated. It is earnestly to be hoped that the Order of St. John will not persevere in any high-handed fashion with its claims. The St. Andrew's Ambulance Association has done the spade work in Scotland for 24 years, and now when, thanks to its efforts, the public in Scotland are waking up to the value of ambulance work the Order of St. John proposes to step in and reap the fruits. That, at any rate, is how the matter must appear to us. There can be no doubt that the granting of the petition of the Order of St. John will be bitterly resented by those who have given their time and money to developing the St. Andrews Ambulance Association.

Glasgow Royal Infirmary: Post-Graduate Classes.

The summer course will this year be a short but very complete one, including, besides instruction in general Clinical Medicine by Dr. J. M. Cowan and in Clinical Surgery by Mr. J. H. Pringle and Dr. H. Rutherford, the following special subjects: Symptomatology of the Nervous System, by Dr. Walter K. Hunter; Surgical Diseases of the Urinary Organs, by Dr. David Newman; Gynaecology (A), by Dr. J. K. Kelly; Gynaecology (B), by Dr. G. Balfour Marshall; Diseases of the Eye, by Dr. H. Wright Thomson; Diseases of the Skin, by Dr. Alexander Morton; Diseases of the Throat and Nose, by Dr. Robert Fullerton; Anæsthetics, by Dr. J. King Patrick; Gynaecological Pathology, by Dr. W. D. Macfarlane; Operative Surgery, by Dr. Peter Paterson; and Bacteriology, by Mr. David McCrorie. These courses will be thoroughly practical, the amount of material at the disposal of the teachers being so large that they have every facility of illustrating their lecture demonstrations by clinical cases. During last year the attendance on the various courses was most encouraging. The attendance at the classes (not including members of the staff) numbered 137 members. It is therefore very desirable, in order to facilitate arrangements, that members of the profession who wish to join any of the classes should communicate as early as convenient with the superintendent, who will enrol members and supply any information desired.

April 9th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Association for Housing the Very Poor of Dublin.

THE annual meeting of the Association for Housing the Very Poor of Dublin was held at Trinity Chambers on April 8th, Sir Lambert Ormsby, the chairman, presiding. This is a small company, but it has already done work that is much needed, for it is recognised that the wretched state of the tenement houses is one of the chief causes of the high mortality in the city. Sir Charles Cameron complimented the association on the way the tenements in its charge were kept and said that although those in Derby-square were reconstructed houses, the rooms were model ones and sanitary in every detail. A dividend of 3 per cent. was declared on the capital of the company.

The Public Health of Belfast.

At a meeting of the public health committee held on March 28th, the medical officer of health reported on certain insanitary areas, and it was decided to appoint a subcommittee to visit these localities and to draw up a report and recommendations for the consideration of the health committee. On April 25th and following days it is proposed to take evidence before the Health Commission in reference to the Belfast water. For the week ended March 23rd the death-rate was 23·5 per 1000. At a meeting of the city corporation held on April 2nd it was reported that between Feb. 17th and March 16th the large number of 302 cases of infectious disease had been notified—viz., 64 enteric fever, 58 scarlet fever, 28 simple continued fever (evidently typhoid), 4 puerperal fever, 27 diphtheria, 1 croup, 19 erysipelas, and 164 cerebro-spinal meningitis. There were 263 deaths registered from chest diseases. The average annual death-rate was 23·7. These returns show a very high number of infectious diseases notified and suggest that, as so often happens in Belfast, another epidemic of typhoid fever may be coming. A very decided opinion was expressed by many members of the corporation against the waste of money in employing counsel at the Health Commission. It was finally settled to agree that the Lord Mayor should let the chairman of the public health committee know what were the ideas of the members of the council in regard to their being legally represented at the Commission. A very curious point was referred to—that was a resolution appointing a deputation of the public health committee to visit some towns in England and Scotland with a view to ascertain methods of public health administration—in other words, a resolution to send Belfast officials to other cities to learn their business.

The Belfast City Fever Hospital.

Dr. G. Orr, medical officer of Ballyleeson Dispensary, has reported to the Lisburn board of guardians at a recent meeting that since the establishment of the Purdysburn Infectious Hospital in his district he has had to register all the deaths which took place in that institution. This entailed hardship on the relatives of the deceased who had to travel another mile after their journey of two or three miles from the nearest train to the hospital. The dispensary patients were naturally alarmed at the presence of people from all parts of Belfast who came to register deaths from infectious diseases, a feeling much intensified by the occurrence of two deaths from cerebro-spinal fever in the neighbourhood, one case being that of the dispensary caretaker and the other of a boy who two days previously had been in the dispensary for some medicine. It is clear that the Registrar-General will have to constitute the hospital a special Belfast district, so that a resident official may be appointed registrar and thus avoid the evils referred to.

Rainfall in Belfast in March.

In March 4·89 inches of rain fell on 21 days, making the amount for the year 1907, so far, 9·78, which is a little above the average amount.

The Health Commission in Belfast.

The Belfast Health Commission resumed sitting on April 8th, when Sir John Byers was examined at both sittings on that day and again on Tuesday. He dealt very fully with the various problems confronting Belfast and made a number of suggestions for establishing a really efficient modern public health department in Belfast.

April 9th.

approved in spending £40,400 on feeding the children, but there is another subsidy of £40,400 which is divided among the maternal schools, the health colonies, various homes for orphans, and different institutions connected with primary education. The teaching itself is, of course, obligatory and gratuitous and all the other services connected with the schools are likely to become equally gratuitous.

Such a tendency in England would doubtless not fail to excite much opposition. It was in 1884 that children attending the Paris elementary schools were first fed on a large scale at the public cost. Paris has therefore had 23 years of practical experience of what has not yet been done anywhere in England. But a law has now been passed. The Provision of Meals Act of 1906 empowers the English school authorities to take some steps in this direction. All the arguments now brought forward in England against the free feeding of children were heard in France a quarter of a century ago. What has become of such arguments in the face of practical experience is shown by the facts and figures given above. Some will be tempted to deplore the result; none can afford to ignore this Paris experience, for it constitutes the greatest object lesson that has ever been given on the subject. The Paris experiment is not as radical as that attempted by the municipality of Vercelli where, as already described,² every child is compelled to take his midday lunch at school and no parent is allowed to pay, but then Vercelli is quite a small place, while Paris is the second largest town in Europe. In 1905 there were in Paris 202 public schools for boys and 202 public schools for girls. The number of pupils inscribed were 79,698 boys and 74,124 girls. Of these 24,023 boys and 14,157 girls attended school during the holidays, where they were watched and fed but not taught. The allowing of children to play in the school building instead of the streets during the holiday is an excellent measure to keep them out of mischief and to insure their being properly fed. Altogether the town of Paris spends on primary education about £1,280,000 and the feeding of the children does not amount to one-thirtieth of the entire outlay. The cost is therefore in no wise to be compared with the importance of the service. The benefits to public health and to the growing intelligence of the pupils are generally recognised to be out of all proportion compared with the expenditure; no outlay has ever given better results.

Of course, the feeding is but part—doubtless the most important and expensive part—of a whole system of physical education. One advantage of the meal at school is that when the attending school physician prescribes a special diet or certain medicaments with the meal the pupil gets them. At home such medical instructions would not always be as punctually executed. Then the great harm done by calisthenics when imposed on starving school children is avoided, because in the Paris schools the children cannot starve. Finally, when consumption and other diseases may be avoided by sending the child to the country or seaside this can often be done as there is a large municipal subvention for that purpose. If we compare the completeness of all these measures, the care with which they have been combined to supplement each other, with the comparative chaos that prevails in the English elementary schools, it is not surprising to find that so much more is said about physical degeneration on the British than on the French side of the Channel.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

Slums.

THE medical officer for the Northwich urban district in his annual report makes some interesting remarks on the effect of "slums" on the health and *morale* of the population. He believes that proper housing would lower the mortality by more than one-half, would decrease infectious disease by three-fourths, would sweep away nearly all the anæmic, undersized, scrofulous beings who now crowd our alleys, almost stamp out tuberculosis, and do much to elevate the moral and mental refinement of the bulk of the people and lessen the need for workhouses, prisons, asylums, sanatoriums, epileptic colonies, and hospitals. This is a long catalogue of benefits, and perhaps a somewhat optimistic view, but there is no doubt that the evils named, with their accompanying

wretchedness, would be greatly alleviated if houses were light, airy, and wholesome, and overcrowding was abolished. It is to be feared, however, that no improvement would follow very rapidly. The "residuum" is not yet educated up to a very high level, and his instincts are not those of a high civilisation. Also it is a splendid notion to "check the erection of slums by the jerry-builder, and provide houses of a proper character for those who need them." But unfortunately that kind of work in Manchester has proved costly to the ratepayers, and municipal enterprises do not seem to be managed with the care and economy necessarily exercised in private ventures.

Afraid of a Hanging Man.

A strange incident came to light at the coroner's court the other week when the death of a man by hanging was being inquired into. He was 75 years of age, and was found by his niece suspended by a rope to a clothes' rack. She did not cut him down, nor did her husband, as they said "they were too unnerved." The coroner suggested that they wanted to be quite sure the man was dead. "He looked as if he was dead." They sent for a policeman who came in half an hour. "So you left him for half an hour?" "Yes, sir." Speaking to the jury, the coroner said that some day a verdict of manslaughter would be brought against people who left anybody hanging and did nothing. Such an occurrence as this shows a degree of mental and physical unreadiness enough to make one almost hopeless as to the future of a large proportion of our urban population. In any emergency, instead of being alert and ready to act promptly, they are timorous to imbecility. It is to be presumed that both the niece of the poor suicide and her husband have shared the blessings of the education that has been so liberally imparted for the last 30 or 40 years, but what effect has it had in giving them character or courage? It would have been well if the man had gone through such an amount of military drill as to bring out some of the readiness to act that the book knowledge which he must be supposed to have imbibed evidently failed to give. The verdict was one of "*Felo de se*," and the jury gravely agreed with the remarks of the coroner as to "the folly of leaving anybody hanging."

Dirty Milk.

The farmers of Saddleworth are indignant at charges having been made of uncleanness in their dairies and carry the war into their customer's country by complaining that some of them are anything but cleanly. They say that jugs are used for days together without being washed, and if the farmer protests he is told that they *must* be clean because they have had nothing else in them but milk. Sometimes, say the purveyors, customer's milk has to be poured into old salmon tins and jam pots. It is difficult to eradicate habits of slovenliness and dirt which have become habitual to too many of the working population, and there need be no wonder that the farmer sometimes hits back.

April 9th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENT.)

The St. Andrew's Ambulance Association.

A POINT of considerable importance, more especially to those interested in ambulance work in Scotland, has been raised by the action of the Order of St. John of Jerusalem in petitioning the Privy Council for a supplementary charter to enable it to establish priories in Scotland. The St. Andrew's Ambulance Association has lodged a counter-petition submitting that the power to establish priories in Scotland would, if granted, be detrimental to the interests of the public and unjust to the Association. The St. Andrew's Ambulance Association was established in 1882 with the object of providing instruction in ambulance work in Scotland and rendering first-aid to the injured and a Royal Charter of incorporation was granted in 1899. The Association has been very successful indeed in carrying out the objects for which it was incorporated, and has now come to be recognised as an important charitable and philanthropic institution. An ambulance corps of 2500 officers and men has been distributed in sections throughout Scotland and the corps is rapidly increasing in numbers. Upwards of 400 classes are conducted by the Association every year and the area of instruction embraces

² THE LANCET, Nov. 10th, 1906, p. 1308.

Health Office." The address was illustrated by microscopical specimens and contained suggestions for the prevention of tuberculosis on lines similar to those in every-day use at the present time. Arrangements have been made for creating a memorial to commemorate this great discovery.

Small-pox.

The epidemic of small-pox which is at present prevailing in France has passed the Franco-German frontier and the disease has made its appearance, especially at Metz. A considerable number of cases have occurred there, but to the annoyance of the adversaries of vaccination it is found that the disease attacks only persons who have not been vaccinated. In the frontier districts and in Metz also there are a great many foreigners who have come from countries where vaccination is either not compulsory or else is not efficiently performed. In Metz and its neighbourhood thousands of Italian workmen live who are employed there, as in a great part of the continent, in the building trades. As they are neglectful of vaccination and as their standard of living is inferior to that of the native population they are peculiarly liable to contract small-pox. The disease is also of frequent occurrence among the French and Belgian residents in Metz, whilst the German inhabitants, who have all undergone vaccination, are exempt. The French newspapers have called attention to these facts and are recommending compulsory vaccination after the example of Germany where small-pox, apart from the frontier districts, has been quite unknown for years.

BUDAPEST.

(FROM OUR OWN CORRESPONDENT.)

Pulmonary Tuberculosis in Budapest.

Dr. Gustav Thürring, director of the city statistical bureau, has published the details of last year's death-rate from various diseases in Budapest. He states that during the last 32 years 85,813 of the inhabitants died from tuberculosis, this disease accounting for 22 per cent. of all the deaths. Owing to recent improvements in the hygienic conditions of the city the death-rate from tuberculosis is now considerably lower than in former years. In 1876 the proportion of deaths caused by this disease was 855 per 1,000,000 of the population, but last year it averaged only 373 per 1,000,000. The death-rate of men is much higher than that of women. The unmarried are much more liable to death from pulmonary tuberculosis than the married of either sex. The death-rate from tuberculosis was comparatively low in districts inhabited by the wealthy classes, but was very high in districts where the poor live in flats and where the accommodation for a family consists either of one room or at most of two rooms.

Tragic Death of a Medical Man's Wife.

In Brassó, a large country town in Hungary, the wife of a medical practitioner—Dr. Flechsenbaum—became ill and it was absolutely necessary that an operation should be performed. Her husband wished her to go to a sanatorium where a member of the staff would do what was required, but she insisted on her husband performing the operation himself, because she would not on any account let another man touch her. He therefore telegraphed for another medical man, a relative of hers, and the two proceeded to perform the operation at the patient's home. It was almost completed when a serious hemorrhage occurred, which they were unable to check, so that the patient died on the operating table. The unfortunate husband is prostrated with grief.

Medical Organisation in Hungary.

In the Budapest Medical "Casino" Dr. Turán Bölg recently delivered a very interesting address on the subject of the influence exercised by the various medical organisations on the social, ethical, and material position of the profession at home and abroad. He said that it was of great importance to the community at large that medical education should be efficient and that public hygiene should receive proper attention; the position of the medical profession, therefore, could not be a matter of indifference for the State. He maintained that the status of the medical profession was unsatisfactory in most parts of Europe but that its prospects were best in the industrial countries where the standard of living was good and where culture and public health were at a comparatively high level. Of the various professional organisations the best results were shown by voluntary

associations built up on a sound economical basis. The prospects of the medical profession in Hungary were gloomy and would be further aggravated by the poverty of the people, by the extension of the system of insurance against sickness (*Arankenkassen*), and especially by the new Workmen's Compensation Act. Improvement could be expected only from organisations which also served at the same time the community at large.

Hungarian Surgeons on Board Cunard Steamers.

According to the Hungarian emigration law every vessel carrying over 500 emigrants from Hungary must have a Hungarian surgeon on board. This regulation has a particular reference to the Cunard steamers, which carry twice a week more than 1000 Hungarian passengers from Fiume. Hungarians have, in fact, been employed as second surgeons on the Cunard steamers since 1904, but none of them look on their appointments as permanent because they see that a position of that kind held for many years would be almost unbearable. In the first place, they have no prospect of advancement because the company holds out no hope that they will ever be transferred to saloon steamers, in which the pay is higher and in which extra fees may be received. Another grievance is that the Hungarian law orders the ship surgeons to send information to the Government about the state of health of the emigrants, whereas the Cunard Company strictly prohibits the giving of information. The Hungarian surgeons are also subordinate to the captain and some others of the ship's officers, as well as to the English surgeon. The pay is very little—only 6s. 8d. a day, with full board. Dr. Henrik Neumann, who was in the Cunard Company's service for two years, has therefore asked the Board of Physicians to negotiate with the company with a view to improve the position and to increase the pay of the Hungarian ship surgeons.

April 6th.

ROYAL COLLEGE OF SURGEONS IN IRELAND.—The

following is the list of prizes awarded for the winter session, 1906-07:—Descriptive Anatomy: Junior: J. T. Duncan, first prize (£2) and medal; and T. Dowzer, second prize (£1) and certificate. Senior: H. G. P. Armitage, first prize (£2) and medal; and W. Swan, second prize (£1) and certificate. Practical Anatomy: First year: T. M. Thompson, first prize (£2) and medal; and F. W. Warren, second prize (£1) and certificate. Second year: W. Swan, first prize (£2) and medal; and H. G. P. Armitage, second prize (£1) and certificate. Practice of Medicine: C. Greer, first prize (£2) and medal; and G. S. Lewis, second prize (£1) and certificate. Surgery: G. S. Lewis, first prize (£2) and medal; and W. R. Burton, second prize (£1) and certificate. Midwifery: H. W. White, first prize (£2) and medal; and G. S. Lewis, second prize (£1) and certificate. Physiology: H. M. Adoo, first prize (£2) and medal; and O. G. Connell, second prize and certificate. Chemistry: P. F. Crowe, first prize (£2) and medal; and J. T. Duncan, second prize (£1) and certificate. Pathology: I. Scher, first prize (£2) and medal; and C. Greer, second prize (£1) and certificate. Physics: J. T. Duncan, first prize (£2) and medal; and T. Buckley, second prize (£1) and certificate.

LITERARY INTELLIGENCE.—The third edition of Vol. II, Part 3, of Allen's Commercial Organic Analysis is just ready for publication. The subjects dealt with are: Acid Derivatives of Phenols, Aromatic Acids, Resins and Essential Oils. Much of the work of revision has been done by Mr. A. R. Tankard, F.C.S., deputy agricultural analyst for Monmouthshire and the county borough of Newport. With its issue the complete work in eight volumes may now be procured. The publishers are Messrs. J. and A. Churchill.—Messrs. Baillière, Tindall, and Cox announce that they are publishing a third edition of "The Diagnosis and Modern Treatment of Pulmonary Tuberculosis, with Special Reference to the Early Recognition and Permanent Arrest of the Disease," by Dr. Arthur C. Latham; a fifth edition of "Treatment by Hypnotism and Suggestion, or Psycho-Therapeutics," by Dr. C. Lloyd Tucker; and a work on "Meat and Food Inspection," by Dr. W. Robertson, medical officer of health of Leith and Perth. The same firm has published a second volume completing the "Manual of Anatomy (Systematical and Practical)," by Dr. A. M. Buchanan, professor of anatomy, Anderson's College, Glasgow, and a work on "Ulceration of the Cornea" by Dr. Angus Macnab, chief clinical assistant to the Royal London Ophthalmic Hospital.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

The Police and the Preservation of Water-courses.

THE Minister of Agriculture has appointed a commission to study the recently proposed legislative and administrative measures to complete the existing laws concerning the preservation by the police of non-navigable water-courses, springs, and underground water, with a view to safeguard them for useful purposes; the commission will be presided over by the Minister of Agriculture.

An Unusual Case of Epithelioma.

The case occurred in a young girl, aged 22 years, who had already been twice operated upon for a cyst of the lower jaw. In spite of repeated cauterisation a suspicious ulcer had persisted and enlargement of the glands was noticed. On further examination a solid tumour was found over the ascending ramus of the maxilla. M. Morestin operated through the mouth and completely removed half the lower jaw, besides extirpating the diseased cervical glands. There has been no recurrence during two years. The tumour proved to be an epithelioma of stony hardness and is an instance of the metamorphosis of a cystic tumour to a solid one. M. Maucclair, who communicated this case to the Société de Chirurgie (March 27th) in M. Morestin's name, is inclined to question whether the total resection that was performed was really absolutely necessary.

Gift to the Academy of Medicine.

The Academy of Medicine has been given authority to accept, under the conditions and terms expressed, the legacy left it by M. Roussilbe, the interest of which is to be devoted to the foundation of a prize to be awarded periodically to the investigator who shall make the greatest advance in dermatology. The prize is to be known by the founder's name.

A Method of Inducing Hemostasis in Hemophilia.

Dr. Emile Weil has shown that fresh animal or human serums in doses of three drops to the cubic centimetre of blood induce coagulation to a moderate degree in hereditary hemophilia and completely in the idiopathic disease where normally the blood would coagulate in five or ten minutes. In practice, to stop or to prevent hæmorrhage in an adult hæmophile from 10 to 20 cubic centimetres should be injected hypodermically. Rabbits' blood should be used for this purpose. This method was communicated to the Chirurgical Society on March 6th by M. Broca on behalf of Dr. Emile Weil.

Boulimia (Sitomania).

At the Neurological Society on March 7th M. Gilbert Ballet recalled the fact that when two cases of boulimia were shown at a previous meeting he had opposed the opinion of other authorities that this disease was an impulsive psychosis and had tried to prove that, on the contrary, it belonged to the intermittent variety, particularly to melancholia. A third case that he had recently seen, in which the boulimia was followed in a fortnight by typical melancholia, gave support to his theory of its pathogenesis. M. Dupré replied that it would be better not to say that boulimia was a variety of melancholia but that the two diseases might be associated, for otherwise phenomena of excitement and depression would seem to be developed simultaneously.

Fatal Influenzal Pneumonia and Enteritis.

At the Hospitals Medical Society on March 22nd M. Siredey and M. Tinel reported two cases of patients suffering from influenza pneumonia, who both developed symptoms of severe enteritis, with frequent and excessive diarrhoea, the stools being of a mucous character and followed shortly by collapse and death. They compare these to two other surgical cases where death occurred in a similar manner, but these latter were not followed with so much care as their own and they can only be quoted to show that this affection forms a more frequent complication of influenza than is generally believed. From cultures made from stools the authors were able to isolate two varieties of micro-organisms whose characteristics were ill defined and did not conform to any known type.

April 8th.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

Report of the Medical Officers to Schools.

Professor Hartmann, the chief medical officer to the Berlin municipal schools, has presented his annual report to the Berlin municipal authorities. The report states that there are 36 medical officers to the Berlin schools, which are attended by 225,237 children. There were 32,902 children examined by the medical staff previously to their entering a school and 3056 of them were refused admittance on the ground of suffering from various bodily and mental diseases. Of the new pupils 7335 were put under special supervision, and these added to the number already under special supervision made up a total of 29,622 children in this category. The report mentions that a good understanding prevailed between the medical officers and the teaching staff; the parents, however, sometimes thought that it was a part of the duties of the medical officers to attend their children in cases of illness. Even teachers in several instances held this erroneous opinion and sent sick children to the private consulting rooms of the medical officers. In Berlin the children were examined in the presence of the mother or some other relative and if found to be healthy no other examination took place. The parents were in general very grateful for suggestions made by the medical staff as to preserving the health of the children and they listened attentively to the advice given to them during the examination of the children. They also received a pamphlet, published by the Berlin Society for School Hygiene, containing the principles of hygiene for children. This pamphlet was, moreover, posted on the walls of the schoolrooms. The report then gives particulars with respect to recent improvements in the ventilation, heating, and sanitary arrangements of the schools. An inquiry was held in one school on the use of spirituous liquors by children and it was ascertained that 2 per cent. of the children took spirits regularly, while 2.1 per cent. took wine and 8 per cent. took beer. A special investigation on the hours of sleep was also carried out by one of the medical officers. He found that 10 per cent. of the children went to bed later than 10 P.M., and he argues that the schools in Berlin begin at too early an hour—namely, at 7 A.M. in summer and 8 A.M. in winter. From 10 to 20 per cent. of the children go to school without having had a warm breakfast. About 40 per cent. of them sleep together with other persons in the same bed, either with their parents or with brothers and sisters, and the report draws attention to the fact and the danger of this custom is open to several objections, both of a moral and of a hygienic nature. The prevalence not only of diphtheria, scarlet fever, and other acute diseases, but also of tuberculosis, is, of course, greatly favoured by this practice. In the next place the report deals with the subject of employments in which school children are engaged. It is stated that a great many of them earn money, especially by going on errands, and some of them are at work early in the morning before school begins, the consequence being that they are very tired and inattentive during lessons. The teeth of the majority of the children proved to be very much neglected; only a minority of them brushed their teeth and of these only very few had a tooth-brush of their own, most of them using one in common with other members of the family. The report then gives particulars as to the prevalence of infectious diseases and the temporary closing of schools as a preventive measure during epidemics of scarlet fever, diphtheria, &c. It will be seen from the above summary that the report of the medical officers to the Berlin schools contains a great amount of valuable and interesting material and that although their office is of recent creation these gentlemen have done a good deal to improve the health of the children.

Commemoration of the Discovery of the Tubercle Bacillus.

Professor Löffler, writing to the *Deutsche Medicinische Wochenschrift*, draws attention to the fact that on March 24th it was 25 years since Professor Robert Koch made his first public announcement with respect to the etiology of tuberculosis. For personal reasons it was before a rather small society—namely, the *Physiologische Gesellschaft*—that he read his celebrated paper which on the agenda of the proceedings figured modestly as "An Address on Tuberculosis by Dr. Koch, Member of the Imperial

THOMAS HENRY WARLEY, F.R.O.S. ENG.,
SENIOR EDITOR OF "THE LANCET."

Obituary.

THOMAS HENRY WAKLEY, F.R.C.S. ENG.,
SENIOR EDITOR OF THE LANCET, CONSULTING SURGEON TO THE
ROYAL FREE HOSPITAL, AND JOINTLY SENIOR FELLOW OF
THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

WE regret to announce the death at his residence in Queen's-gate of Thomas Henry Wakley, the senior proprietor and editor of this journal. Thomas Wakley (he deliberately made no use of his second name) was born on March 20th, 1821, and had therefore passed the eighty-sixth anniversary of his birthday by a few days when he died. He was the eldest of the three sons of Thomas Wakley, the well-known coroner and Member of Parliament, who, by founding THE LANCET, inaugurated a movement for medical reform the extent of which can hardly be realised, especially as revolutionary movements at present taking place are the direct outcome of his original programme. He dropped the use of "Henry" in his name possibly because his next brother, Henry Membury Wakley, also bore the name, but with more probability because the great affection and reverence in which he held his father made him prefer to be called, like him, simply "Thomas Wakley." THE LANCET made its first appearance two and a half years after the birth of the founder's son, the subject of this memoir, but that the son should succeed in the father's footsteps as editor of the journal, which grew up with him, was in a certain measure an accident. Thomas Wakley was educated with the intention that he should enter the Church, and with this view was carefully tutored in the classics preparatory to his matriculation at Oxford. It is a point of interest that his private tutor was the Rev. James Basnett Mills who was also private tutor to the famous Platonist and Master of Balliol, Benjamin Jowett.¹ As a lad Thomas Wakley showed great aptitude for the *literæ humaniores*, but his connexion with the University of Oxford was extremely brief. At the time of his matriculation his father was a leading Radical, one of the foremost in the House to promote the more reasonable part of the Chartist programme without actually subscribing to Chartist doctrines. But such emancipated opinions were not acceptable at Oxford, where young Wakley found the political and social creed which he had been brought up to admire regarded as not very distinguishable from high treason. Fortunately, the University of London had been founded a few years previously as a practical protest against the limitations of the older universities every whit as much as with the idea of promoting the cause of metropolitan or imperial education, and to the University of London Thomas Wakley took himself, selecting the medical faculty of University College for his labours and giving up all idea of the Church. In these days the medical teachers or professors of University College were an extremely distinguished band, numbering among them Samuel Cooper, of the Surgical Dictionary;

Liston, the most marvellous operator in London; Richard Quain, the author of the Anatomy of the Arteries; Anthony Todd Thompson, author of "The Dispensatory"; Robert Carswell, the famous pathologist; Robert Grant, the comparative anatomist; and Sharpey, the leading physiologist of the day. An industrious student had extraordinary opportunities at such a school, and young Wakley became known to more than one of his teachers as a promising pupil, showing in particular great aptitude for surgery and surgical anatomy. He was also admirably coached, for his father, with the same determination that had previously led to the selection of Mr. Mills as a classical coach—a determination, namely, that the young man should enjoy the best possible educational advantages—now persuaded Erasmus Wilson, at that time lecturer on anatomy at the Middlesex Hospital, to read with his son. Wilson and his pupil got on well together and Wakley acted as demonstrator at his coach's private classes with great benefit to himself. In the year 1845 he took the diploma of Membership of the Royal College of Surgeons of England, having previously proceeded to Paris in deference to his father's views that the scheme of medical education enjoyed by the Parisian students was preferable to that of the London medical schools.

In Paris he lived most of the time of his sojourn with Dr. J. Henry Bennet, the gynaecologist, and was an assiduous attendant at all the clinics of the best operating surgeons in the city. When he was not engaged in his medical studies he spent his time and his money in taking music lessons (from Garcla among other masters) with the result that when he returned to England he was a trained musician and good French scholar as well as a surgeon of large experience considering his age. His knowledge of French to his regret deteriorated, but he retained his love of music during all his life; indeed, so lately as 1903, on the occasion of the marriage of a very near relative, he composed a wedding march which, we believe, attained a considerable amount of favour. In the year 1848 he was elected assistant surgeon to the Royal Free Hospital, a hospital which was started in 1828 in a building at Hatton-garden as a protest against the system of letters by which the subscribers to the medical charities of London were able to dispense patronage upon exclusive principles. This hospital made a great stride forward in 1842 when it was removed to its present site, and the appointment formed an admirable opening for a young consulting surgeon. Wakley entered into the spirit of his duties with enormous enthusiasm. He felt that he had got his chance while he was quite a junior man, but, although he was by no means blind to the advantages of having his father and THE LANCET at his back, he now set out with the deliberate intention of making a name for himself in surgery. He took a house in Guilford-street so that he might be quite near the hospital and for several years became, more or less on his own initiative, casualty surgeon to the institution. His house was so near to the hospital that it was inevitable that the resident staff should appeal to him in all cases of difficulty, and he was delighted with the opportunities which he thus got for increasing his experience. But

¹ Early in its career THE LANCET was printed and published in Fleet-street by the firm of Mills and Jowett, and Mr. J. B. Mills and Professor Jowett were respective sons of the members of the firm.

he was soon to find that the value of having a distinguished father might be considerably discounted if that father happened to be an aggressive man. Many of our readers know the literary and business methods which characterised the first 25 years of the life of THE LANCET. The journal was founded to remedy the numerous abuses from which members of the medical profession suffered in their professional life, and on all occasions the founder and editor took the shortest course towards the results which he wished to attain. He mixed words with no one, he spared no man's feelings, he did an incalculable lot of good, he made a great many distinguished friends, but he also raised up a host of enemies, many of them well-known and influential people who quite honestly regarded his methods as pernicious. Now if there was one point upon which the editor of THE LANCET was more clear and more eloquent than another it was the mischief done at the metropolitan hospitals by the appointment through nepotism of the wrong men to fill the posts on their staffs. When, therefore, the son of the editor of THE LANCET, while still a young man and with a record for work behind him which had largely been accomplished in another country, was appointed to the staff of the Royal Free Hospital, all the critics of THE LANCET, honest as well as prejudiced, were prepared to consider that the appointment was an example of the very abuses against which THE LANCET was never tired of fulminating. Young Wakley soon became conscious that his hospital practice was attracting an amount of interest not usually manifested in the work of so young a practitioner, and when the opportunity of the opponents of THE LANCET came he was not found unprepared. Wakley was accused of malpraxis in a case of fracture in a child complicated with scarlet fever. He refused to pay blackmail to the parents and disregarded the publication of a scurrilous and indecent pamphlet purporting to be a record of the case, although this was hawked about the street where he lived. An action was at length brought *in forma pauperis*. The accusation came at an extremely unfortunate moment for Wakley, as he had intended to present himself at the end of the year 1849, just about the probable date of the trial, for his final examination for the Fellowship of the Royal College of Surgeons. Moreover, it was reported that some of the examiners had been subpoenaed to appear for the prosecution. At this juncture Wakley displayed great powers of resolution. He was ordered by his father not to present himself for the examination on the ground that the mental strain would militate against his chances, and that if he failed the fact would inevitably come out at the trial and damage him in the eyes of the jury. The founder of THE LANCET was a masterful man and it was not the habit of his children to say him nay, but Wakley resolved to proceed with the examination unknown to his father and passed triumphantly on Dec. 6th, 1849, a date which, by the way, made him at the time of his death senior Fellow of the College bracketed with Mr. George Carrick Steet, who took the same diploma on the same day. The trial came on on Dec. 10th and was a veritable triumph for Wakley. The only surgeon called for the plaintiff gave evidence for the defendant, the

unanimous opinion of the distinguished authorities appearing as witnesses for the defendant could not be questioned, and the private malevolence which, together with the hope of blackmail, had instigated the prosecution was fully revealed. The jury, who had previously manifested a desire to stop the case, found a verdict for Wakley without leaving the box.

Shortly after this Wakley, whose position as an operating surgeon was now well established, moved from his unambitious address in Bloomsbury to No. 7, Arlington-street, where he enjoyed for many years a good surgical practice, many of his clients belonging to the highest ranks of society. With regard to several such patients, when the lapse of time had removed all possible chances that he was committing any breaches of professional confidence, he used to tell humorous stories. One in particular dealt with a man famous in the history of England. An old gentleman who would never give any name used to come day after day, often several times in a week, to consult Wakley about a chronic ailment of his foot. He declared that he had consulted some of the first surgical opinions in the country about his trifling ailment and that they had been unable to do anything for him. He proposed that he should pay Wakley a definite sum every week and that Wakley should attempt a systematic cure. He was told that he could come when he liked if he paid the usual fee, which at that date was one guinea. He would not give his name. After a time the foot began to yield to treatment and a pleasant source of revenue for a young surgeon in a new and expensive house bade fair to cease. Still Wakley remained in ignorance of the identity of the old gentleman. But one day his servant came to him in much excitement and said that he had suddenly remembered why the mysterious patient's face had been familiar to him from the first. He had seen him at prize-fights and he was Lord —, mentioning a great peer who is reported to have twice refused to be Prime Minister of this country, and who certainly after the death of the Duke of Wellington had succeeded to the unofficial post of private general adviser to the Crown. Wakley always considered it a joke against both Lord — and himself that he should not have known by sight so distinguished a man living a stone's throw from his door, and that the recognition should have come from his servant through the mutual taste of the butler and the peer for what was then called "the noble science." While in Arlington-street Wakley made a special study of diseases of the urethra and invented an ingenious form of dilator which in his hands gave very good results. He was also the first observer to see the use to which glycerine might be put in practical surgery owing to its deliquescent properties. An article on the point, published in THE LANCET attracted considerable attention and incidentally gained for him some reputation as an aural surgeon, as it was in relation to the treatment of affections of the external auditory meatus that his experiments were made. He also wrote the article upon Diseases of the Joints in one of the later of the many editions of Samuel Cooper's famous

¹ We prefer to imitate Mr. Wakley's discretion, even though it is easy to see to whom the reference must be.

"Surgical Dictionary," and published an interesting series of experiments in the anaesthetisation of various animals and birds.

In 1857 his father, who five years previously, owing to ill-health, had resigned his seat in Parliament, made an arrangement by which his eldest and youngest sons became part proprietors of THE LANCET and had a share in the management of the journal. In 1862 the father died and the editorial conduct of THE LANCET passed to the youngest brother, the late Dr. James Wakley, who, indeed, in all but name had been editor for several years, but Thomas Wakley as part proprietor of the paper was actively interested in its conduct. From this time his life as an active surgeon to some extent was doubled with the life of a journalist, although he did not actually retire from consulting practice until 1882. But he came daily to THE LANCET office and acquired such experience of practical journalism that he was able upon the death of his brother in 1886 to assume the editorship in association with his son. Dr. James Wakley had been educated and bred as a journalist, while Thomas Wakley turned to journalism comparatively late in life, but under his rule the journal has steadily progressed. His ideas were always shrewd and practical; for instance, the publication weekly of an index of advertisements was due to him, and the convenience of the innovation has since been recognised by other papers. We cannot be expected to criticise him in his capacity, as our senior editor; that must be left to other pens, but we may be allowed to say that from the first he made good headway against the inevitable drawbacks of entrance upon the career of a journalist at so late a date in his life, and that he was unsparing of himself in his energetic desire to do good by the medium of his journal. Of unbounded activity, physical and mental, he was never ill and never absent from his duties. In all weathers and on all occasions he arrived in the early morning at his office. For many years he spent the winter months in Brighton but he never allowed this to interfere with his regular and punctual attendances at THE LANCET office. So late as 1903, when he was in his eighty-second year, he made the journey from Brighton to London and back daily, not omitting even Saturdays. During the last decade of his life the editorial management of the journal gradually passed from the hands of the father to the hands of the son, but to the end of his life Thomas Wakley showed no abatement of interest in the details of the paper. He continued to come daily to the office and could always be relied upon in cases of unusual difficulty or doubt for a sound and sensible consulting opinion. One subject he retained in his own hands entirely. During all the period in which he was associated with the editorship of THE LANCET great prominence was always given to the work of the Hospital Sunday Fund. The Fund was largely founded by Dr. James Wakley, and Thomas Wakley resolved that the interest manifested by his brother should not be allowed to die out. He personally supervised the publication every year of a special supplement issued in the interests of the Fund, and was an assiduous attendant at the meetings of the General Purposes Committee, of which he was a member, and of the meetings of the Council. His deep sympathy with the material welfare of the medical profession was shown not only by many acts of private generosity but by the institution of THE LANCET Relief Fund. The income of this Fund since its foundation in 1889 has been supplied by himself and his son as the proprietors of THE LANCET. The Fund was intended to meet unforeseen and urgent pecuniary exigencies among members of the medical profession, and the proved utility of this scheme of practical generosity was always a source of great gratification to its originator. He was also a warm supporter of Epsom College, his advocacy of this useful foundation taking in 1902 the practical form of a

donation of £1000, given in the name of "The Proprietors of THE LANCET," while he was always ready to support the claims of the College, educational as well as eleemosynary upon medical practitioners. He was interested in the ambulance department of the Order of St. John of Jerusalem, was Knight of Grace of that Order, and a member of the committee of the Jerusalem Ophthalmic Hospital.

Mr. Wakley's private life was a very quiet and retired one. He married when a young man the third daughter of the late Francis Radford Blake of Rickmansworth, so that the year of his golden wedding had gone by when he died. Outside his duties as surgeon and journalist Mr. Wakley's chief pleasures lay in sport. In his youthful days he had been a fine runner and athlete. He was a first-rate rider, and until quite late in life hunted whenever he got the opportunity. He was fond of salmon fishing, regularly visiting Ireland for many years for the purpose. He was also, like his brother James, an enthusiastic shot, and until the end of his days took the greatest delight in the sport.

With regard to his last illness—which within the memory of all who knew him was his first illness—there is little to be said. Some six or seven weeks ago he found himself troubled with attacks of breathlessness. He was assiduously cared for by Dr. Alfred Baldock in consultation with Sir Richard Douglas Powell, and in his temporary absence with Sir Lauder Brunton, but it was not possible to arrest the increasing cardiac weakness. An absolutely uncomplaining patient, in the end he peacefully passed away in the presence of his family. He was quite prepared for the event, having stated his belief when he first consented to seek medical advice that his days were numbered. He leaves a widow; a son, Thomas Wakley, junior, who has for the last 20 years been his father's colleague in the editorship of this journal; and a daughter.

A funeral service was held in St. Mary Abbots Church, Kensington, on Wednesday, April 10th. The vicar of the parish, Canon Pennefather, took the service, being assisted by the Rev. J. A. Lewis. Among those present were Mr. Henry Morris, President of the Royal College of Surgeons of England; Dr. S. Monckton Copeman, representing the Medical Department of the Local Government Board; Sir Shirley Murphy, medical officer of the County of London; Dr. D. Nicolson, O.B., Lord Chancellor's Visitor in Lunacy; Dr. John Tatham, superintendent of statistics to the General Register Office; Sir Edmund Hay Currie, representing the Metropolitan Hospital Sunday Fund; Dr. Dawson Williams, Editor of the *British Medical Journal*; Sir Guy Elliston, secretary of the British Medical Association; Sir Henry Bardett, K.O.B.; Mr. Conrad W. Thies, secretary of the Royal Free Hospital; Mr. J. B. Lamb, secretary of Epsom College; Mr. W. Shroeder, deputy coroner for Central London; Dr. J. G. Glover, Mr. Sandford, Mr. D. R. Harrison, Dr. A. Baldock, Mr. O. McCall, and many past and present members of the editorial staff of THE LANCET, and members of the printing and publishing departments. After the service, in accordance with the wish of the deceased, the remains were cremated at Golder's Green.

The admirable portrait on the adjoining page is reproduced from a photograph taken when Mr. Wakley was aged 85 years. The presentation is life-like.

A great many letters of sympathy have been received by us, of which we select the following for publication, with the permission of the writers, who in each case were old-established and personal friends of Thomas Wakley:—

100, Harley-street, W., 7th April, 1907.

MY DEAR MR. WAKLEY,—I am deeply grieved to receive the news of your father's death. When I realise that he is no more my thoughts insensibly go back to the time when I first came to know him, five and thirty years ago. At once I was impressed by his robust physique, alertness, and vigour. His handsome face, his well-knit frame, his elastic

of white phosphorus in match making. It states that many manufacturers, and Messrs. MOSELAND among them, have spent considerable sums of money in the endeavour to make a "strike anywhere" match without white phosphorus, but in spite of various inventions, some of which are strongly advocated by those who have patented them, it does not seem that they are yet in a position entirely to replace the white phosphorus match. Custom, no doubt, has some influence and it is also said that matches made with white phosphorus have the advantage of greater resistance to damp and greater freedom from explosive ignition, not only in manufacture but also in use by the consumer. The report proceeds to say that it would, of course, be easy, and would relieve the Factory Department of much trouble, to put an end to the possibility of necrosis by totally prohibiting the use of white phosphorus. But this step would seem logically to involve the prohibition of the use of many other substances which are largely used in industry and which have caused a much larger number of industrial accidents. Mr. CURTIS and Dr. WHITELEGGE for the present do not think that the character of the cases of necrosis which have occurred render it necessary to prohibit the use of white phosphorus.

There is another solution of the difficulty to which they look forward with hope. They are of opinion that an effective remedy can be found in automatic machinery with exhaust ventilation so arranged (1) that the whole of the fumes generated are completely carried off without coming in contact with the workers, and (2) that it is impossible for the paste to come in contact with the workers' hands or persons. Pending the introduction of completely automatic machinery it is obviously important to insist upon the greatest care being taken with regard to the very few persons in the factory who are exposed to phosphorus. Mr. CURTIS and Dr. WHITELEGGE recommend that the special rules in force in lucifer match factories should be strengthened and that the various firms engaged in the industry should be pressed to arrange for automatic machinery which shall completely isolate the operatives both from fumes and from the paste. They further suggest that an Inquest should always be held in case of a fatality attributable to phosphorus and that the attention of coroners should be especially directed to this point.

Public Health in Egypt.

In a Blue-book containing Lord CROMER's report on the administration of Egypt, No. 1 section relates to public health. 31,000 in-patients and 123,000 out-patients were treated in Government hospitals in Egypt last year. 1910 cases of small-pox were notified, as against 4189 in 1906; the number of plague cases has increased, however. Infant mortality continues very high. The lunatic asylum accommodation has recently been enlarged and a new asylum is to be opened at Khanka; it is hoped that during the current year Lord CROMER's previous suggestion of the necessity of a lunacy law will bear fruit. The campaign against ophthalmia continues vigorously, the necessity of establishing permanent ophthalmic hospitals to replace the tents for treatment is fully recognised and the first will be opened at Tantah during this year. The Government Anti-Rabic Institute has been working since May, 1906, with excellent results, and Professor R. Ross's campaign against mosquitoes in Port Said has greatly diminished malarial and other fevers. Similar action is being taken at Suez and Cairo.

Medical Education.

The Board of Education has issued as a Blue-book the reports from universities and university colleges participating in the Parliamentary grant. These include the Universities of Birmingham, Leeds, and Liverpool; the Victoria University, Manchester; King's College, London; University College, London, and Dundee University College. Particulars are given in each case where medical degrees and diplomas are granted of the number of students who have studied for them and of the scale of class fees.

HOUSE OF COMMONS.

MONDAY, APRIL 8TH.

Magistrates and Vaccination.

Mr. CLARKE asked the Secretary of State for the Home Department whether he was aware that the Lambeth magistrate had refused a certificate of exemption from vaccination.—Mr. GLADSTONE: The law requires an applicant to satisfy the magistrate that he conscientiously believes that vaccination will be injurious to the child and therefore I cannot take any action in the matter.

Osborne Convalescent Hospital.

In the course of the debate in Committee of Supply on the vote for £200 in respect of Osborne Mr. HARCOURT, the First Commissioner of Works, said, in replying to several Members, that the draining in connection with Osborne House had been found to be very bad when it was taken over as a convalescent hospital for officers of the army and navy. However, it had been thoroughly overhauled and now the building was possessed of the highest requirements for a convalescent hospital. His department had taken pains that it should have a good water-supply. Complaints had been made that Osborne was only available for officers of the army and navy and was not open to the non-commissioned ranks. Those who made that complaint had forgotten the terms of the gift of Queen Victoria. That was a splendid gift, and it had been received in an Act of Parliament. By its terms a part of the grounds and of the house was to be kept as at present as a memorial to her late Majesty, and the rest of the House was to be devoted to officers of the army and navy.

Mr. MORTON said that he saw in the estimates an item for the Osborne advisory committee. What was their work?

Mr. HARCOURT answered that this advisory committee was composed of a number of eminent surgeons and medical men who gave their services gratuitously to his department in making periodical inspections and in satisfying him that the hospital was being properly conducted. He thought that the least they could do was to pay the travelling expenses of these gentlemen. For his own part he could not speak too highly of the distinguished men who had given them the benefit of their services in this manner.

The subject then dropped and the vote was agreed to.

TUESDAY, APRIL 9TH.

A Seizure of Tinned Goods.

Mr. BRIST LAMB asked the President of the Local Government Board whether he was aware that at a recent auction in the City of London (March 27th, 1907) a large quantity of tinned goods were offered for sale, some of which were seized and destroyed as unfit for food by the port sanitary authority in whose district they were lying, although the owner of the goods stated that some of these goods were returned military stores from South Africa; and whether he was aware that a quantity of these goods were still in this country and on the way, and that arrangements were apparently being made to put them on the market from time to time at the rate of one-halfpenny per pound after expense of freight, storage, &c., had been paid; and whether, in these circumstances, he would take such steps as might be necessary in the interests of public health to prevent such sales.—Mr. JOHN BURNS (by written answer) replied: The facts appear to be generally as stated. Further legislation of the kind contemplated by the Public Health (Regulations as to Food) Bill now before Parliament is necessary for the proper dealing with a matter of this kind, but in the particular instance mentioned attention was given by the local authorities concerned to the condition of the goods sold at the auction. A special notice was exhibited at the auction to the effect that they were sold subject to being passed by the medical officer of health of the district in which they were lying; and steps were taken by the medical officers of health of the City and Port of London, of Stepney, and of Finsbury to obtain the surrender of such of the articles of food as were considered to be unfit for human consumption.

WEDNESDAY, APRIL 10TH.

Floods and Public Health in Ireland.

Mr. MEETHAM asked the Chief Secretary to the Lord Lieutenant of Ireland whether his attention had been called to the medical evidence given before the Barrow Drainage Commission in 1885 by Dr. William Neale, medical officer, Mountmellick dispensary district, to the effect that houses were annually rendered unfit for habitation, and whole families had to leave in flood times and were huddled together in most insanitary houses, public health seriously injured, malaria and typhoid fever and diphtheria prevalent in consequence of the floods and that no adequate sewerage for the town was possible, and the water-supply was contaminated; and whether, having regard to the fact that the evils arising from the flooding had increased since this evidence was given 22 years ago, he would take steps to provide an effectual remedy. The honourable Member also addressed a question to the Prime Minister on the same subject in which he drew attention to the medical evidence given before the Barrow Drainage Commission by Sir Francis P. McCabe to the effect that the flooding of this area developed various diseases, including pulmonary phthisis, bronchial and catarrhal affections, and acute and chronic rheumatism.—Mr. BURELL replied to both questions: The Arterial Drainage Commission has only recently reported. The appendix containing the evidence has not yet been presented to Parliament. It is, however, in the printer's hands and will shortly be ready. When the evidence has been received it will be necessary to consider the recommendations of the Commission on Arterial Drainage as a whole in order to decide what legislation may be necessary and this will take time. It is obvious that in the meantime it will not be possible or desirable to consider the question of undertaking a drainage scheme for the Barrow or any other particular river. This answer applies also to the question which the honourable gentleman has addressed to the Prime Minister.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to THE LANCET Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week such information for gratuitous publication.

ANDREW, GEORGE WAYLAND, M.B., C.M. Edin., L.R.C.P. & S. Edin., L.F.P.S. Glasg., has been appointed Honorary Surgeon to the Gloucester General Infirmary and Eye Institution.
ANGELLIS, A. A., M.D. Athens, L.S.A. Lond., has been appointed Clinical Assistant to the Evelina Hospital for Children, Southwark.
BLACK, EDWARD HAMPTON, M.B., Ch.B. Edin., has been appointed Assistant House and Visiting Surgeon to the Stockport Infirmary.
BUTCHART, JOHN E., L.R.C.P. & S. Edin., L.F.P.S. Glasg., has been appointed Resident Medical Officer of Austin Hospital for Incurables at Heidelberg, Victoria, Australia.
DAVIES, LESLIE, M.B. Melb., has been appointed Acting Officer of Health, Goulburn, New South Wales, Australia, during absence on leave of Mr. Robert George Reid.
DR. ZILVA, LUCIAN ARNOLD EMMANUEL, M.D., R.Sc. Lond., has been appointed Third Physician to the General Hospital, Colombo, and Lecturer in Physiology at the Ceylon Medical College.
ERCOLE, G. M. D. Bologna, has been appointed Medical Officer at the Grenfell Hospital, New South Wales, Australia.
GALLAGHER, J. M.B., M.S. Edin., has been appointed Certifying Surgeon under the Factory and Workshop Act for the Burgo District of the county of Lincoln.

de Miranda, L.M. & S., Bombay and King's College; Anthony Dias, King's College; George Douglas Gordon Fergusson, St. Mary's Hospital; Bernard Goldsmith, Middlesex Hospital; Alfred Barnes Gunasekara, Ceylon Medical College; Clifford Hall, Manchester University; Newcombe Herbert Harrison, Charing Cross Hospital; Arthur Hilary Clifton Hill, Middlesex Hospital; John Brookwood, St. Thomas's Hospital; Ernest Howden, Leeds University; Gwilym James, B.A. Cantab., King's College; Geoffrey Jefferson, Manchester University; Bertram Abbott Keate, St. Bartholomew's Hospital; Timothy Joseph Killard-Leavey, Guy's Hospital; Musunguesen Muthu Kumarasamy, Madras; Francis William Lastie, Sheffield University; Julius Luciani, M.D. Venezuela, University of Caracas; Kenneth Dalrymple Marriner, St. Thomas's Hospital; Robert Telford Martin, London Hospital; Maurice Charles Mason, St. Mary's Hospital; Bernard Constable Maybury, St. Thomas's Hospital; John Frederick Henry Morgan, University College, Bristol; Claude Woodham Morris, University College Hospital; Francis Leslie Nash-Worham, St. Bartholomew's Hospital; Charles Philip Augustine de Lacerda Pereira, Birmingham University; Wilfrid Langrish Pink, St. Thomas's Hospital; George Henry Pooley, F.R.C.S. Edin., Cambridge University; Frederick Charles Priddham, St. Thomas's Hospital; Edward Albert Seymour, St. Thomas's Hospital; Frank Lewis Smith, St. Thomas's Hospital; Vere Edward Somerset, King's College; Horace Steinbach, Guy's Hospital; Thomas Edmund Alexander Stowell, St. Thomas's Hospital; Alan Everley Taylor, D.A. Oxon., Oxford University; Charing Cross Hospital; James Massimo Todesco, London Hospital; Henry Ashburn Treadgold, B.A. Cantab., Cambridge University; Thomas Anger Perseman Tyrrell, St. Mary's Hospital; Louis Michael Waldron, London Hospital; John Pryce Williams, Manchester University and St. Mary's Hospital; and Raphael Yood, Manchester University.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—

At the preliminary science examination for the Licence in Dental Surgery the following gentlemen were approved in the subject of chemistry and physics:—

Ernest Beddoes, Holt School of Science, Birkenhead; Harold Rawbert Bentley, Technical School, Halifax and Leeds University; Henry Montague Browne, Science and Art Institute, Walsall; Victor Charles Burt, Charing Cross Hospital; Robert Morris Colwill, City of London College; Henry Charles Corke, Battersea Polytechnic; Niel Edgar, Birkbeck College; James Nutrie Frank, Technical School, Liverpool; John Trude Frupp, Polytechnic Institute; Lionel David Frihauf, Birkbeck College; John Wilfrid Hall, Guy's Hospital; Arthur Rusby Hawksley, Technical School, Liverpool; Percy Stanley Humm, Guy's Hospital; William Edward Jones, Technical Schools, Chester; William Joseph Kennedy, Guy's Hospital; Rupert Mallinson, Charing Cross Hospital; Christopher Claud Marston, Technical School, Leicester, and Birmingham University; Bertie Mendleson, Municipal Technical School, Swansea; Henry Leslie Messenger, Birkbeck College; Frederick Henry Newcombe, Holt School of Science, Birkenhead; James Ormrod, Technical School, Liverpool; Bertram Charles Salter, University College, Aberystwyth; Walter Herman Seales, Technical School, Liverpool; Norman Stefan Heegard Warner, Wandsworth Technical Institute; Alexander MacDonald Watson, Guy's Hospital; Lauder Lylestone Wight, Birkbeck College; Frederick Charles Willows, University College, Bristol; and Thomas Edwin Wills, Polytechnic Institute.

SOCIETY OF APOTHECARIES OF LONDON.—At

the primary examinations held recently the following candidates passed in the subjects indicated:—

PART I.

Chemistry.—I. M. Bernard and M. O. Dence, Royal Free Hospital. *Materia Medica and Pharmacy.*—C. A. Morlock-Brown, Royal Free Hospital; and G. F. Wilson, London Hospital.

PART II.

Anatomy.—E. O. R. Fisher and A. Jonathan, Royal Free Hospital; B. A. Keats, St. Bartholomew's Hospital; H. W. Phillips, Manchester; J. E. S. Sheppard Jones, Cambridge and St. Thomas's Hospital; A. Singha and H. H. Smith, Royal Free Hospital; S. W. Turtle, London Hospital; and H. I. Welsh, St. Mary's Hospital.

Physiology.—J. A. Bullbrook, Guy's Hospital; B. A. Keats, St. Bartholomew's Hospital; J. E. S. Sheppard-Jones, Cambridge and St. Thomas's Hospital; H. H. Smith, Royal Free Hospital; and W. E. N. Smith, Durham.

LONDON SCHOOL OF TROPICAL MEDICINE.—The

following students of the above school successfully passed the examination in Tropical Medicine held at the end of the twenty-third session, January to April, 1907:—

*Major F. R. Ozzard, I.M.S.; *Captain T. G. N. Stokes, I.M.S.; *Mr. J. M. O'Brien (Colonial Service); *Lieutenant O. Berkeley-Hill, I.M.S.; M.B. Oxon.; *Captain J. W. F. Hail, I.M.S.; Dr. A. W. Atkinson (Colonial Service); Dr. M. Gamble; Mr. F. W. Woolrabe; Dr. E. G. H. Weir (Colonial Service); Dr. A. Orguier (Torino); Dr. C. W. McLeay (Colonial Service); Dr. E. W. Wood-Mason (Colonial Service); Dr. A. M. Cowan; Mr. R. W. Orpen (Colonial Service); Dr. F. McF. W. Pollard (Colonial Service); Dr. A. M. Clark; Mr. W. N. Alexander (Colonial Service); and Dr. H. O'Hara May (Colonial Service).

* With distinction.

NORTH DEVON INFIRMARY, BARNSTAPLE.—The

Countess Fortescue on April 5th in the presence of a large gathering formally reopened the North Devon Infirmary. The institution has been enlarged and brought thoroughly up to modern requirements. New wards have been added,

including a new isolation ward, the expense of the latter having been defrayed by a legacy received from the late Mr. Staples. The cost of the undertaking has been about £24600, the whole of which sum has been raised.

UN SOUND MEAT.—At the Weston-super-Mare petty sessions court held on April 5th a local butcher was sentenced to two months' imprisonment for having meat unfit for human consumption exposed for sale in his shop.

MEDICAL MAGISTRATES.—Mr. Philip Edward Hill, M.R.O.S. Eng., L.S.A., of Crickhowell, Mr. Frederick James Jayne, M.B., C.M. Glasg. of Talgarth, and Mr. Hubert Williams, L.S.A., of Talgarth, have been placed on the commission of the peace for the county of Brecknock.

THE COAL SMOKE ABATEMENT SOCIETY.—The annual general meeting of this society will be held on Monday, April 22nd, at 3 p.m., at the Haymarket Theatre, Haymarket, London, W., under the presidency of Sir William Richmond, K.C.B., R.A. It is expected that, among others, the following will take part in the proceedings: The Bishop of London, Sir Frederick Treves, Mr. W. H. Atkin Berry, F.R.I.B.A., Dr. H. A. Des Vœux (honorary treasurer of the society), and Dr. S. Rideal, F.I.O.

INVALID CHILDREN'S AID ASSOCIATION.—The

annual meeting of the Invalid Children's Aid Association will be held, by kind permission of the Right Hon. the Speaker and Mrs. Lowther, at the Speaker's house in the Palace of Westminster on Wednesday afternoon, May 1st, at 3 o'clock. Lord Strathcona will preside and Sir William Bennett, K.C.V.O.; the Rev. Father Bernard Vaughan, Mr. Creighton, and Mr. I. Zangwill will be among the speakers. Admission by ticket only, application for which may be made to the Secretary, 69, Denison House, Vauxhall Bridge-road, Westminster, London, S.W.

ROYAL INSTITUTION.—A general monthly meet-

ing of the members of the Royal Institution was held on April 8th, Sir James Orichton-Browne, treasurer and Vice-President, being in the chair. Dr. J. Percy Smith and Mr. A. H. Tubby, F.R.C.S., were among the elected members. The special thanks of the members were returned to Sir Andrew Noble for his donation of £200 to the Fund for the Promotion of Experimental Research at Low Temperatures; and to Lady Kelvin for her gift of a statuette of Lord Kelvin. The chairman announced the decease of Professor M. Berthelot, Hon. Mem. R.I., and of Dr. Allan Macfadyen, Fullerton professor of physiology in the Royal Institution 1901-03, and resolutions of condolence with the relatives were passed.

LONGEVITY.—The Times of April 8th states that

Mrs. Hamilton of Townend, Kirkcudbright, celebrated the 103rd anniversary of her birthday last week. She was born on April 4th, 1804, the daughter of Mr. Robert Gordon, a banker and writer, of Kirkcudbright. Her husband, the Rev. George Hamilton, died in 1836, after being for 16 years minister of Kirkcudbright. Of the family of three sons and two daughters, one son and the daughters survive. Mrs. Hamilton still enjoys as good health as is compatible with her great age and the Kirkcudbright town council presented her with an illuminated address on the anniversary of her 100th birthday. Last month the approaching anniversary was brought to the notice of Lord Knollys, who was commanded by the King to telegraph to Mrs. Hamilton a message of congratulation.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

The Easter Holidays.

THE House of Commons reassembled on Monday after the Easter Holidays. The House of Lords do not meet until next week.

Phosphorus Necrosis in Match Factories.

The report made to the Home Secretary by Mr. H. S. CUNYNGHAM, Assistant Under-Secretary of the Home Office, and Dr. B. A. WHITELEGGE, Chief Inspector of Factories, on the match factory of Messrs. MORLAND and SONS, Gloucester, with special reference to a recent fatal case of phosphorus necrosis, has been presented to Parliament. They reported that in the present instance no rules appear to have been broken. The report concludes with some general remarks and recommendations on the employment

Notes, Short Comments, and Answers to Correspondents.

A GREAT ESTATE, ITS AGENT, AND THE MEDICAL PROFESSION.

Our readers may remember that we refused recently to publish an advertisement sent to us by Mr. Henry Whitcomb in behalf of the Petworth Park Friendly Society. In the first instance we refused the advertisement because we were not supplied with the rules of the society, later a letter received from Mr. Herbert E. Watson, agent to Lord Leconfield, the owner of Petworth, confirmed us in our decision (see THE LANCET, Jan. 26th, 1907). Mr. Watson was annoyed with us for publishing his letter, which was not marked "private," but he grew positively angry with us later for not publishing some figures which reached us in another letter, this time marked "private and confidential." Legal proceedings were spoken of unless we complied with Mr. Watson's behests, and altogether it was made clear to us that we had a very dour opponent to deal with. Yet with perhaps unpardonable rashness we kept on doing nothing, and the advertisement has not been inserted.

Mr. Watson has now issued a pamphlet with this title, "A Correspondence in Reference to an Advertisement for a Medical Officer between the Petworth Park Friendly Society and 'The Lancet.'" He calls attention on the frontispiece that only three of the letters have been published in THE LANCET, but adds in the preface that he has "decided to print the whole of the correspondence." Upon this pamphlet we have one or two remarks to make. Firstly, we are quite pleased to re-read our letters to Mr. Whitcomb and Mr. Watson. They well explain our position. But they were not written for publication, and their issue without our sanction is a droll proceeding on Mr. Watson's part considering his views about the sanctity of his own letters to us. Secondly, it is incorrect to describe the correspondence in the preface as complete when it is nothing of the sort. Modesty no doubt may have led Mr. Watson to refrain from giving wide circulation to his first letter of Jan. 23rd or to his letter of Feb. 1st, 1907, in which he informed us that "the general remark of the leading people of this place" was "I never heard of such a thing publishing a private letter and commenting on it in such a vulgar way." The omission of these communications, however, renders the correspondence the reverse of complete. Thirdly, there is a footnote on page 11 of the pamphlet which is disingenuous. We stated in THE LANCET dated Jan. 26th that we had "never seen the rules of the Petworth Park Friendly Society." The footnote challenges our statement, saying, "N.B.—The rules we forwarded on January 24th, see my letter. THE LANCET was published on January 26th.—H. E. W."; and the implication is that we had received the rules but preferred to deny the fact. Mr. Watson must know that a paper has to be printed before it is published. THE LANCET dated Jan. 26th went to press on the afternoon of Jan. 21st, three and a half hours before Mr. Watson posted to us in Petworth the rules which he said had been omitted owing to an oversight of his clerk (see letter on page 9 of pamphlet). Fourthly, the valuer's report, which appears on page 10, is unsigned and undated in the pamphlet, but in the original it is both. Despite these blemishes the pamphlet is a useful little production and we wish it wide publicity. Possibly Mr. Watson is doing his best to meet our wish.

At the same time as we received the pamphlet we received a copy of the following circular letter which has been sent—at least we suppose so by the internal evidence of Mr. Watson's first suggestion—to a number of secretaries of medical aid associations or sick clubs—

(CONT.)

THE MEDICAL ASSOCIATION & FRIENDLY SOCIETIES.

Petworth, Sussex, March, 1907.

SIR,—It may have come to your notice that the medical profession are taking up the question of the pay given by various societies to their Medical Officer.

The P.P.F.S. are now experiencing the methods adopted by the Medical Press in order to secure their object. The M.O. of this society asked for higher pay: The Committee informed him that they could not advise the members to give it consequently (after 5 yrs. service) he resigned. A general meeting of the members was called & they endorsed the action of the Committee & decided to offer the appointment to a firm of doctors in the town who, on account of etiquette I presume, declined it. The Society then advertised the appointment. To their surprise the medical papers (LANCET and B.M.J.) declined to take the advt. the former paper giving 2 reasons for not doing so (1) The Editor had not seen the rules & (2) He had received an intimation that the appointment was not such as could be recommended to the Medical Profession.

The information came from the late Medical Officer and was based on incorrect data.

I will not add to the length of this letter by going through all the phases of this question but will ask you to be good enough to pursue this. I enclose (corres. with LANCET). The result is this

- (1) On no account will they reinstate their medical officer.
- (2) The only other doctors (one firm) will not take the appointment.
- (3) The Medical Press not only decline the advertisement but put the Society on their black list till they can screw them up to give such remuneration as in the opinion of the Medical Association is fair.

My object in addressing you is to ascertain your views on the following suggestions.

(1) That all the Friendly Societies of England should join in some concerted action in order to put down the tyranny of the Medical Press in preventing men (who by their thrift are saving the rates) from making their wants known to the Medical Profession through the medium of the Medical Press: Surely educated men are competent to fix or arrange their own salary with a club without the aid of a Union.

(2) It is impossible to fix a hard and fast line for the salaries of Medical Officers which can only be done by deciding each case on its merits, distance & other considerations having to be considered.

(3) There should be a co-operation of the various clubs within a given area & a doctor with a fixed salary appointed to attend so many clubs.

(4) A meeting of delegates within the area should meet and discuss the question.

If the above meet with the approval of your club I will be glad to arrange a meeting at some place to be agreed when the whole matter can be thoroughly gone into.

Yours faithfully,

H. E. WATSON.

We shall be interested to learn what developments follow. It is our tyranny apparently that is to be put down, and we are wondering how Mr. Watson is going to make us insert advertisements which we do not think are ethically correct.

APPARATUS FOR ELEVATING THE HIPS IN BED.

To the Editors of THE LANCET.

SIR,—The principle advocated by Dr. E. G. Gilbert in THE LANCET of March 23rd, p. 817, to prevent a patient slipping downwards is correct, but if I may, as a layman, find fault with the way in which the result is secured I would venture to point to the wooden cross-bar on which the base of the spine (or the small of the back) rests, which on a non-yielding mattress would be hard enough, but in one that gives with the weight of the patient's body it would be torture; presumably this one does, or lying flat on his back as he is there depicted there would be no possibility of downward "creeping." Again, there is a similar bar across under the knees, and in a lesser degree the same criticism applies.

The Equipolse Company make a bed, referred to in your columns on a recent occasion (vol. 1, 1905, pp. 236 and 307) of which the mattress frame is in three parts, back, seat, and leg rest. As the back rises the rear of the seat and foot end of the leg-rest decline, leaving the knees raised, the weight of the body being all the time fully supported by the woven-wire mattress, whilst, moreover, the seat being at an incline, it prevents any tendency towards slipping downwards; these positions are attained smoothly and without exertion by the patient or attendant and there are no cross-bars from head to foot in contact with the body, a great point in bedridden cases.

I am, Sirs, yours faithfully,

Ashford, Kent, March 26th, 1907.

H. P. CLEMETSON

LIBERIA: ITS CLIMATE AND DISEASES.

Captain C. Braithwaite Wallis, British Consul at Monrovia, in his report on the trade, &c., of Liberia for the year 1906, just received at the Foreign Office, enters at some length into the question of the climate and diseases of the country.

In the Americo-Liberian settlements there are practically no drainage and little or no attempt at sanitation. The most trying seasons of the year are the beginning and end of the rains. At these times malarial fever of a severe type is prevalent and the Americo-Liberians suffer nearly as much from this disease as do Europeans. The aboriginal adult, however, although he suffers from malarial fever, seldom dies from it. A chief source of the spread of malarial fever amongst the inhabitants is by the bite of the infected anopheles. As the blood of nearly every native child has been found to contain malarial parasites it can be well understood how readily the disease is spread. From careful investigations made on the spot it has been found that anopheles caught in native villages invariably contained a large percentage of infected specimens.

The geographical distribution of malaria in Liberia is general owing to the anopheles existing probably throughout every part of the territories of the Republic. At Monrovia, owing to the number of stagnant ponds and pools, the anopheles abound. European merchants and others live, as a rule, in close vicinity of native houses. There has been no attempt here at segregation, and a high percentage of the European residents at Monrovia and the other ports on the Liberian coast are malarially infected. Every European dwelling-house illustrates the deadly practice of being surrounded by, or in the immediate vicinity of, numerous native huts and dwelling-places, which, as a rule, contain a certain number of children. The commencement and end of the rains are the unhealthy seasons because at these periods the anopheles are more prevalent. In the former case the larvae are allowed to develop owing to the rainfall

QUIRKE, J., L.R.O.P. & S. Irel., has been appointed Certifying Surgeon under the Factory and Workshop Act for the Infatigable District of the county of Kilkenny.
 RIDDLELL, W. H., M.B., Ch.B. Edin., has been appointed House Surgeon at the Staffordshire General Infirmary, Stafford.
 ROSE, FRANK A., M.R.C.S., L.R.O.P. Lond., has been appointed Assistant Surgeon to the Throat Department at St. Bartholomew's Hospital.
 STREETEN, FRIEND EDWARD, M.R.C.S., L.R.O.P., L.M. Edin., D.P.H. Irel., has been reappointed Medical Officer of Health of Swindon.
 WADDEY, HENRY EDWARD, L.R.O.P., M.R.C.S., D.P.H. Camb., has been appointed Honorary Consulting Surgeon to the Gloucester General Infirmary and Eye Institution.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

ASHTON-UNDER-LYNE DISTRICT INFIRMARY.—Junior House Surgeon. Salary at rate of £75 per annum, with board, attendance, washing, &c.
 BIRKENHEAD UNION INFIRMARY AND SANATORIUM.—Resident Assistant Medical Officer. Salary £123 per annum, with board, washing, and apartments.
 BIRMINGHAM, QUEEN'S HOSPITAL.—Second Physician for Out-patients and Pathologist. Salary £100 per annum.

THE Chief Inspector of Factories, Home Office, S.W., gives notice of a vacancy as Certifying Surgeon under the Factory and Workshop Act at Chudleigh, in the county of Devon.

Births, Marriages, and Deaths.

BIRTHS.

GREENE.—On April 4th, at Richmond House, Turvey, Beds., the wife of George Watters Greene, M.A., M.D., of a daughter.
 PANK.—At Hamilton-place, Market Rasen, Lincs., the wife of Harold W. Pank, M.R.C.S., L.R.O.P., of a daughter.

MARRIAGES.

LYNCH-CROSBY.—On April 8th, at the Church of St. Nicolas, Tanfield, Yorkshire, by the Rev. G. P. H. Felt, M.A., George Wm. Augustus Lynch, J.P., B.A., M.B. Cantab., Senior Medical Officer, Colonial Medical Service, P.O. to Katharine Stuart Frances Crosby, Stenford Park, Ripon. Colonial papers please copy.
 MAY-MITCHELL.—On April 6th, at St. Peter's and St. Paul's Church, Chingford, Essex, George Ernest May, M.R.C.S., L.R.O.P., to Rachel Marguerite, second daughter of the late William Augustus and of Mrs. Mitchell.
 YOUNG-BIRON.—On April 6th, at Lymington parish church, Graham Pallister Young, M.B., B.S., to Helen, third daughter of the Rev. Henry Brydges Biron.

DEATHS.

HARRISON.—On April 3rd, at Cornwallis-crescent, Clifton, E. T. D. Harrison, F.R.C.S., in his 88th year.
 LEVY.—On April 8th, at Kingscliffe, Northamptonshire, of pneumonia, Thomas White Lewis, M.D. Univ. Dub., second son of the late J. M. Aylward Lewis, J.P., of Ballinagar, co. Galway, and Mrs. Lewis, 42, Morehampton-road, Dublin, aged 52 years.
 MILES.—On April 4th, at "Motcombe," Hamgate, Thomas Miles, M.R.C.S., in his 84th year.
 WAKLEY.—On April 6th, at 5, Queen's-gate, S.W., Thomas Henry Wakley, F.R.C.S. Eng., eldest son of the late Thomas Wakley, M.P., aged 86 years.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

PHARMACEUTICAL SOCIETY OF GREAT BRITAIN (17, Bloomsbury-square, W.C.).—8 P.M.: Paper.—Mr. J. Humphrey: The Compendium of Medicines, its Plan and Scope.

PATHOLOGICAL SOCIETY OF LONDON.—Meeting postponed.

WEDNESDAY (17th).—ROYAL MICROSCOPICAL SOCIETY (20, Hanover-square, W.).—8 P.M.: Exhibition of Slides of Foraminifera by Mr. A. Barland. Paper.—Mr. H. M. Nelson: On the Podura Scale.

THURSDAY (18th).—HARVEIAN SOCIETY OF LONDON (Stafford Rooms, Titchborne-street, Edgware-road, W.).—8.30 P.M.: Papers.—Mr. Jeffrey: A Case of Ulcerative Colitis treated by Operation under the care of Dr. Latham and Mr. Jeffrey.—Dr. L. G. Guthrie: Some Nervous Affections of Childhood.

FRIDAY (19th).—SOCIETY FOR THE STUDY OF DISEASE IN CHILDREN (11, Chandos street, Cavendish square, W.).—5 P.M.: Clinical Evening for the Exhibition of Cases followed by Discussion. Patients in attendance at 4.30 P.M.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

MONDAY (15th).—POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.).—2 P.M.: Medical and Surgical Clinics. X Rays. Mr. Dunn: Diseases of the Eye. 2.30 P.M.: Operations. MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M.: Dr. S. R. Dore: Clinique. (Skin.) 5.15 P.M.: Lecture.—Dr. H. Campbell: Observations on Treatment.

NORTH-EAST LONDON POST-GRADUATE COLLEGE (Tottenham Hospital, N.).—Cliniques.—9.30 A.M.: Surgical Out-patient (Mr. H. Evans). 2.30 P.M.: Medical Out-patient (Dr. Whipple), Throat, Nose, and Ear (Mr. Carson); X Rays (Dr. Pirie).

TUESDAY (16th).—POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.).—10 A.M.: Dr. Moulton: Gynaecological Operations. 2 P.M.: Medical and Surgical Clinics. X Rays. Dr. Ball: Diseases of the Throat, Nose, and Ear. 2.30 P.M.: Operations. Dr. Abraham: Diseases of the Skin.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M.: Dr. J. E. Squire: Clinique. (Medical.) 5.15 P.M.: Lecture.—Mr. W. H. Clayton-Greene: Retention of Urine.

NORTH-EAST LONDON POST-GRADUATE COLLEGE (Tottenham Hospital, N.).—Cliniques.—10.30 A.M.: Medical Out-patient (Dr. Auld). 2.30 P.M.: Gynaecological Out-patient (Dr. Giles), Surgical Out-patient (Mr. Edmunds), Surgical Operations (Mr. Carson).

WEDNESDAY (17th).—POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.).—10 A.M.: Dr. Ball: Diseases of the Throat, Nose, and Ear. Dr. Saunders: Diseases of Children. 2 P.M.: Medical and Surgical Clinics. X Rays. 2.30 P.M.: Operations. Dr. D. Robinson: Diseases of Women.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M.: Mr. L. Mummery: Clinique. (Surgical.) 5.15 P.M.: Lecture.—Dr. N. Tirard: Some Forms of Pneumonia.

NORTH-EAST LONDON POST-GRADUATE COLLEGE (Tottenham Hospital, N.).—Cliniques.—2.30 P.M.: Skin (Dr. Meachen), Eye (Mr. Brooks), Medical Out-patient (Dr. Whipple).

THURSDAY (18th).—POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.).—2 P.M.: Medical and Surgical Clinics. X Rays. Mr. Dunn: Diseases of the Eye. 2.30 P.M.: Operations.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M.: Mr. Hutchinson: Clinique. (Surgical.) 5.15 P.M.: Lecture.—Mr. E. Clarke: The Fundus Oculi in Health and Disease (with lantern slides).

NORTH-EAST LONDON POST-GRADUATE COLLEGE (Tottenham Hospital, N.).—2.30 P.M.: Gynaecological Operations (Dr. Giles). Cliniques.—Medical Out-patient (Dr. Whiting), Surgical Out-patient (Mr. Carson). 3 P.M.: Medical In-patient (Dr. Chappell).

FRIDAY (19th).—POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.).—10 A.M.: Dr. Moulton: Gynaecological Operations. 2 P.M.: Medical and Surgical Clinics. Dr. Ball: Diseases of the Throat, Nose, and Ear. X Rays. 2.30 P.M.: Operations. Dr. Abraham: Diseases of the Skin.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M.: Mr. M. Yearley: Clinique. (Ear.)

NORTH-EAST LONDON POST-GRADUATE COLLEGE (Tottenham Hospital, N.).—9.30 A.M.: Clinique.—Surgical Out-patient (Mr. H. Evans). 2.30 P.M.: Surgical Operations (Mr. Edmunds). Cliniques.—Medical Out-patient (Dr. Auld), Eye (Mr. Brooks). 3 P.M.: Medical In-patient (Dr. Leslie).

ROYAL INSTITUTION OF GREAT BRITAIN (Albemarle-street, W.).—9 P.M.: Prof. O. S. Sherrington: Nerve as a Master of Muscle.

SATURDAY (20th).—POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.).—10 A.M.: Dr. Ball: Diseases of the Throat, Nose, and Ear. 2 P.M.: Medical and Surgical Clinics. X Rays. 2.30 P.M.: Operations. Dr. D. Robinson: Diseases of Women.

EDITORIAL NOTICES.

It is most important that communications relating to the Editorial business of THE LANCET should be addressed exclusively "TO THE EDITORS" and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET should be addressed "To the Manager."

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES. TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.O., are dealt with by them? Subscriptions paid to London or to local newsgagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and not to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will insure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 15 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.O.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates, on this or on any other ground, should be resisted. The Proprietors of THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues; and Agents are authorised to collect, and generally do so collect, from the Proprietors the cost of such extra postage.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied. Address—THE MANAGER, THE LANCET OFFICES, 423, STRAND, LONDON, ENGLAND.

METEOROLOGICAL READINGS.

(Taken daily at 8.30 a.m. by Steward's Instruments.)

During the week marked copies of the following newspapers have been received:—Western Mail, Peterborough and Hunts Standard, Chatham, Rochester and Gillingham News, Standard, Daily News, Daily Chronicle, Belfast News, Daily Mail, Tribune, Norwich Eastern Daily Press, Hull Eastern Morning News, Haverhill Express, South London Press, Morning Post, Preston Guardian, Durham Chronicle, Daily Guardian, Daily Express, &c.

being as yet insufficient to wash them away. On the other hand, as the rains lessen the drying pools and puddles become more numerous and more adapted for the hatching of the mosquito egg. The rainfall in Liberia so far as has been recorded—from September, 1904, to August, 1905—was registered at 153 inches. In the southern portion of the territories the rainfall does not appear to be so heavy. From the colony of Sierra Leone (which in 1901 registered 175·4 inches) southwards the rainfall seems gradually to diminish, for on the Gold Coast the average is only about 82. Probably Sierra Leone has the heaviest rainfall in tropical Africa, with Western Liberia ranking next. The climate of Liberia varies considerably, improving in proportion to the distance traversed from the littoral.

Owing to the want of sanitation, the difficulty of obtaining fresh food, the unpleasant surroundings, and the extreme humidity, the climate of Liberia is, apart from the prevalence of malarial fever, both dangerous and enervating to the health of Europeans. The European merchant has literally a struggle for existence. Moreover, his staff, if also European, are apt to become, after a little time, lethargic and anemic, and require frequent trips to Europe. But his most insidious enemy is malaria, coupled with the enervating influence of the climate. If he can succeed in avoiding the former his chances of success as a merchant in West Africa will be very much greater.

SHIPPING COMPANIES AND THEIR SURGEONS.

To the Editors of THE LANCET.

SIRS.—Can you spare the space to publish the following warning letter which has been sent to the secretaries of all the medical schools in Great Britain and Ireland, and which may be of interest to many of your readers, especially medical students and those who have recently qualified?

DEAR SIR.—During the past year or so stringent vaccination laws have been passed, affecting immigrants to various parts of the American continent and the West Indies.

Several shipping companies have endeavoured to make their surgeons do the extra work involved without any extra pay, including the filling in of certificates and counterfoils, and in many cases have refrained from giving any hint of this to intending ship surgeons.

Before a qualified man signs the articles of any ship going to North, Central, or South America he should carefully inquire what extra work is expected of him, apart from the health and sanitation of the ship itself, otherwise he may have disagreeable experiences as others have done.

Inclosed please find a copy of the more important clauses of the Argentine law, which gives a good idea of these vaccination laws generally.

If your medical school has a gazette perhaps you might kindly insert this warning letter. I am, Sirs, yours very truly,

MASTOID.

* * The following are the Argentine clauses referred to by our correspondent.—ED. L.

Vaccination Law in Argentina, promulgated June 25th, 1906.

1. That in future steamship agents at the port of embarkation inform all 3rd-class passengers for this country that they must be vaccinated or have been vaccinated within a period of seven years and must hold a certificate to this effect.
2. That passengers who have fulfilled these conditions should receive from the ship's doctor a special certificate to this effect, to be exhibited on arrival at this port.
3. That passengers who have not fulfilled Article No. 1 should be vaccinated by the ship's doctor who will issue them a certificate to that effect.
4. That the steamship companies deliver to the Health Board on the arrival at this port of each ship, together with the counterfoils of certificates issued, a list of passengers who have not complied with Articles Nos. 1 and 3.
5. That 3rd class passengers to which Article 4 refers, who have not been vaccinated before embarkation or during the voyage, be vaccinated immediately on arrival by a doctor of the Immigration Department.
6. That the Health Board examine on arrival certificates issued by ship's doctor, and obtain the counterfoils for statistical purposes, handing over list of persons subject to vaccination on arrival, to the Medical Board of the Immigration Department.
7. That persons resisting vaccination on shore will be punished under Article No. 2 of Law No. 4202.

THE HEALTH OF THE PEOPLE OF INDIA.

We have received a printed "copy of an open letter addressed to the Right Hon. Mr. John Morley, Secretary of State for India," dealing with the subject of the improvement of the Medical and Sanitary Departments of India and praying for an inquiry into their working. The circumstances which led to its publication, and to the Secretary of State for India being addressed through the form of an open letter, are fully set forth in the pamphlet, and indications are given of the many points which, in the opinion of the author—Mr. Sam Manikam, founder and agent, South Indian Railway Mission—loudly call for reform and improvement. We have read the pamphlet. The subjects touched upon cover a wide field and presuppose a knowledge of the alleged facts as well as acquaintance with the hospital routine of India.

THE "KNOCK-OUT" BLOW.

A CORRESPONDENT signing himself "Glove" is anxious to know explanation of the "knock-out" blow. We do not know that the absolute physiology of the effect of the blow has ever been settled, but we believe the result to be caused mainly by two factors. The one is the shock transmitted to the base of the brain by the ram of the lower jaw acting through the thin plate of the temporal bone, and the other is that the head is driven violently backwards, thus giving a shock to the medulla by a stretching of the spinal cord.

"ALGIRON."

Messrs. Evans, Sons, Lescher, and Webb, Limited, of 60, Bartholomew Close, London, E.C., announce that their preparation hitherto known as "Alghind Iron" (Stanford) will be called henceforth by the name of "Algiron." As we have already pointed out this substance consists of a compound of alginic acid (from seaweed) with iron. The salt is said to present a form of iron readily absorbed into the system without giving rise to the disturbances which follow the administration of ordinary iron salts.

F. E. H.—A witness can claim to be paid before he is sworn, but if he is sworn before making the claim he must then give evidence and take his chance of being paid.

L. L.—The official title is medical officer. We cannot pronounce upon the legality or otherwise of a Poor-law medical officer signing himself medical superintendent.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

Medical Diary for the ensuing Week.

MEDICO-LEGAL SOCIETY (22, Albemarle-street, W.).—8.30 P.M.: (1) Three Cases of Fatal Poisoning by Strychnine; (2) A Fatal Case of Poisoning by Bichromate of Potassium (reported by Prof. H. Littlejohn);—A Case of Poisoning by Oxalic Acid (reported by Dr. S. Tebb).

In Address

ON

THE OUTLOOK OF THE MEDICAL PROFESSION: SCIENTIFIC, SOCIAL, FINANCIAL.

Delivered before the North London Medical and Chirurgical Society on April 11th, 1907.

By JAMES GREY GLOVER, M.D. EDIN.,

RESIDENT OF THE SOCIETY; EX-MEMBER OF THE GENERAL MEDICAL COUNCIL.

GENTLEMEN,—A very significant incident in the history of France and of human thought was recorded in the *Times* of Dec. 24th last and has great interest for members of the medical profession. The article I speak of was headed "The Great Men of France," and it relates how it had occurred to one of the most widely circulated French newspapers, the *Petit Parisien*, to take a plebiscite of the French nation on the question of the relative pre-eminence of great Frenchmen in the last century. It appealed to its readers all over France to vote and was rewarded by a response from no less than 15,000,000 of the French people. The result was delightful and, in my humble opinion, profoundly just and true. I shall give you the chief figures in a few lines from the interesting telegram of the *Times* correspondent. "The winner of the recent contest is Pasteur. Victor Hugo runs him close, having received 1,227,103 votes against 1,338,425 for the world-renowned man of science. But it is characteristic that two men of peaceful pursuits should precede on the list of these great Frenchmen who might have appeared at first sight to have most contributed to that special kind of glory known as French. Gambetta follows Victor Hugo with 1,155,672 votes. Then comes Napoleon with 1,118,034 and Thiers with 1,039,453 respectively." The *Times* correspondent well says: "Fifteen million answers have been received and what gives value to this striking demonstration is that we have here the opinion of average France, not that of a political coterie or of a cultivated élite. Such a vote raises one's hopes of the race—almost of Fame itself." Said Milton:

"What is glory but the blaze of fame,
The people's praise, if always praise unmix'd?
And what the people but a herd confus'd,
A miscellaneous rabble who extol
Things vulgar, and well weigh'd, scarce worth the praise?"

Here, I venture to think, is a hopeful exercise of the popular judgment, which well introduces what I have to say of the outlook of medicine from a scientific point of view and which we may well set off against some of the discouraging facts—I hope temporary and evanescent facts—among ourselves as to the popular estimate of the greatest achievements of medicine.

It has been disquieting and humiliating to the medical countrymen of Jenner to watch the outbreak of prejudice against his great discovery. This is not the time or place to labour that question in detail. I am glad here just to say this, that there are slight indications that this aberration is confined to certain sections of the people and even so is showing signs of abatement. Dr. O. A. Wickham of Barnsbury and other friends have supplied me with proof that the public vaccinations keep up to an average and I am delighted to gather from a letter in THE LANCET of March 30th that in the recent London County Council election the antivaccinists got a severe rebuff at the polls, conveying a hint to Liberals that sound Liberalism must not include the right to have an infectious disease, horrible and injurious in itself, and involving great risk to others. But returning to the French plebiscite, you may say "Pasteur was not a physician." Well, in a technical sense he was not, but his earliest interest and yearnings in connexion with his great discoveries had a medical character and found in medicine their most splendid and epoch-making application. In 1863 Napoleon III. wished to see Pasteur. Pasteur was introduced to the Emperor by his distinguished teacher, J. B. Dumas. Referring to the emperor's questionings Pasteur says, "I assured the emperor that all my ambition was to arrive at the knowledge of the causes of pueril and contagious diseases." Less than a week ago we

as a profession and the nation at large celebrated, with the sympathy and congratulations of the civilised world, the eightieth birthday of Lord Lister—the complement of Pasteur—who quickly saw, with no less genius and conviction than those of the French *savant*, the proportions and the significance of the immense discovery that was made by Pasteur, for it determined that living air-borne particles were at the root of fermentation, and, as he soon surmised, at the root of putrefaction, suppuration, gangrene, and infections generally.

Pasteur and Lister together, anticipating so happily the *entente cordiale*, yet working in separate fields, in spite of scoffers and scepticism evolved gradually, but with splendid scientific steadiness, their great views and the application of them to the prevention and cure of disease in animals and plants. In 1866 I was privileged, by detention in Glasgow for a fortnight, to see, and to be deeply impressed by, the application of these views to surgery (as he was then) Mr. Lister, Professor of Surgery in the University, and to learn at first hand the marvellous results in compound fractures and other cases obtained by the use of means to prevent putrefaction in wounds based on Pasteur's discoveries, but perfected from day to day by Lister, till now they constitute the chief glory of surgery and of medicine too. It is indeed not too much to say that the work of these two men, so modest, so careful, so intensely and laboriously and patiently scientific in their methods, with all that has grown out of it, will soon have saved, if they have not already saved, as many lives as Napoleon I. and Napoleon III. together contrived to destroy.¹ It is not only the direct effect of their methods that we have to note here, but the fact that they have established our profession on a firm basis of science and close observation which has raised it in the estimation of men and which must for ever serve as a guide to those who profess the art of healing. In support of this conclusion I need only remind you of the revolution in medical education which is ever aiming at securing in medical students a sounder knowledge of the principles of science and of the fundamental subjects of chemistry and biology as the only safe foundation for teaching of more strictly medical subjects. This change is for the moment trying to many old and famous schools of medicine, but it is beneficent and inevitable and the schools which most heartily recognise and accept it and all it implies, will increasingly attract the majority of students. And men in practice, like ourselves, must catch the contagion and keep abreast as well as we can with the new spirit and methods of medicine.

Before I leave this notice of what I shall call the master-builders of modern medicine it is as tempting as it is unnecessary to say that these men had in their composition not only the subtle and indefinable characteristics of genius but those moral qualities—of faith, of reverence, of high principle—which ever enter into the greatest men, and which have been conspicuous in the leaders of medicine from Hippocrates downwards. If the highest influence of our profession is to be realised it will only be by this combination of intellectual and moral qualities which were eminently illustrated in Pasteur. If I might venture a word of advice to my younger friends in the profession it would be to study biography, and especially that of medical men who have influenced their age or their time. Of all biographies, that of Pasteur seems to me one of the most delightful. He was a devout Roman Catholic but no scientific success lessened either his humility, his reverence, or his faith. Nearly 20 years before his death he was overtaken by hemiplegia and he had early losses by death of those whom he most loved; but he remained still the same loving, trusting, working man and achieved after his hemiplegia some of his greatest triumphs. Death is not for the like of Pasteur. He "*remains*" as his great medical colleague Lister will "*remain*." We may apply to each of them the words of Tacitus: "Quicquid ex Agricola amavimus, quicquid mirati sumus manet, mansurum est in animis hominum, in æternitate temporum, famæ rerum."

But it may be thought that I am getting far away from my subject and that we have to come down to the common men and the common work of our profession and to say what is the outlook for them—socially, politically, if you please financially. I have noticed a tendency in some of my

¹ It is pleasant and only fair here to say that Napoleon III. showed much interest in Pasteur and his work and conferred with much persistence the building of satisfactory laboratories for the promotion of his momentous investigations.

Subscriptions (which may commence at any time) are payable in advance.

An original and novel feature of "THE LANCET General Advertiser" is a Special Index to Advertisements on pages 2 and 4, which not only affords a ready means of finding any notice but is in itself an additional advertisement. Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance. Answers are now received at this Office, by special arrangement, to advertisements appearing in THE LANCET. The Manager cannot hold himself responsible for the return of testimonials, &c., sent to the Office in reply to Advertisements; copies only should be forwarded. Cheque and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Office, 423, Strand, London, to whom all letters relating to Advertisements or Subscriptions should be addressed. THE LANCET can be obtained at all Messrs. W. H. Smith and Son's and other Railway Bookstalls throughout the United Kingdom. Advertisements are also received by them and all other Advertising Agents.

brethren to speak somewhat despondingly of the outlook. They see lions in the way and things that threaten the just influence and rewards of medical labour and travail. And theoretically it does not seem very obvious after you have spent a thousand or a couple of thousand pounds in the education of a son for the profession what is to be his immediate reward. Well, if money were the only reward for medical service I should agree that it is not adequate. But I feel sure that there are counterbalancing considerations which will alter the outlook and make ours for all time an honourable and a fairly satisfying profession. And most medical men in their hearts seem to think so. There is one fact which confirms this view, and that is the number of medical men who put their sons into the profession. For my part, I could imagine no greater joy to a medical man than to be succeeded by a son who gives his heart to the profession and finds his delight in mitigating suffering, "obviating," as Cullen puts it, "the tendency to death" and degeneration in his patients and in the community. So strong is this feeling in many medical men that they send not only a son but sons into the profession—two, three, or six, or eight. This is a pretty clear proof that they think it an honourable profession and one worthy to be followed. I cannot go so far myself. The profession is overstocked and I believe in variety of callings in families. But given some check to overcrowding, and devotion to medical work in the spirit of Pasteur and Lister, I think ours one of the best, if not the very first, calling in the world.

Let us briefly enumerate a few of the obstacles that in the opinion of some are injuring the outlook of medical practice as a calling. They may be said to be: (1) the growth of specialism; (2) the prevention of disease; (3) the license of unqualified practice; (4) the competition of certificated midwives; and (5) the abuse of medical charity.

Let me say a few words on each of these subjects.

(1) *The growth of specialism.*—It is no doubt true that there is public demand for the specialist and that this is carried absurdly far, as if the body consisted of detached parts and members which could be treated apart and without reference to the whole. With accumulating wealth not always accompanied with accumulations of wisdom there will be an increasing number of persons who will be tempted to go straight to a specialist whether their pain be in the little finger or in the great toe. What is the remedy? It is for every general practitioner to make his knowledge as *special* and as *particular* as possible, to be himself vigilant and intelligent in his diagnosis and ready in the use of his remedies. The public is quick to perceive resource and readiness in general practitioners and it is only fair to admit that if consultants are claiming to specialise they are hard run by many general practitioners who find themselves at home in every region of the body and every organ, whether it be the ear or the eye, the uterus or the lungs. The facilities of special clinics and the multiplication of clinical and resident officers in hospitals tend to specialise medical education, and equip the student and practitioner who is in earnest for dealing with all the ordinary ills he is likely to meet with. After all, the general practitioner can often be himself a specialist and the intelligent of the public must see that his ordinary adviser who specialises his knowledge is in the best position to take a large and accurate view of his case and to treat it effectually.

(2) *The wholesale prevention of disease.*—If disease is prevented, as it is on a large scale by municipal measures and by education, it is said that our occupation is threatened. But let me reply that these very municipal measures imply medical service and employ large numbers of medical men. This demand will increase as the hygiene of homes, schools, factories, ships, shops, armies and fleets is more and more urged by law and by sanitary authorities. And there remains the melancholy fact that no efficiency of sanitary law or administration will ever be likely to prevent the thousand and one diseases on which general practice rests. There is, I think, some abuse in the system under which the hospitals of our Metropolitan Asylums Board offer gratuitous treatment to those who are able to pay or to keep and isolate their sick at home. These hospitals were built for the poor. The original Act provided that those who could pay should be made to do so. In the feeding of school children provision is suggested for recovering money from the parents where possible, but it is so much easier for officials and politicians to bleed the taxpayers and to pauperise the objects of

benevolence, that I fear that if care is not taken to revive the old English virtue of independence and thrift we shall lose some of our work in a way that will benefit neither our patients nor the State.

(3) *The license of unqualified practice.*—This has always existed, more or less, and in my judgment cannot be prevented by law. The remedy is for general practitioners to perfect their own superiority over prescribing druggists and quacks of all sorts and to show an interest in the smaller complaints which often harass and hinder so much the life of the working classes. I like that remark of Sydenham, perhaps somewhat exaggerated, contained in a letter to Dr. Brady: "Nevertheless, I have always thought it a greater happiness to discover a certain method of curing even the slightest disease than to accumulate the largest fortune, and whoever compasses the former I esteem not only happier but better and wiser too." It is not with medicine as with law, "*de minimis non curat lex*." Medicine should care much—and here I differ from many—about trifles: small complaints the beginnings of delicacy and ill-health—a toothache, nail-biting, a swollen gland, a pyrexial tendency, defects of strength or colour or animation. Without being fussy it is possible to avert much pain and ill-health and to put people and families on better lines of health. Intelligent care of this kind is much needed in all ranks of life and ought to be rewarded according to the means of those benefited. Such intelligent care is appreciated by all classes of patients, and not least by the working-classes, out of whose modest means one has seen the finest spirit of gratitude and received some of our most precious if small fees. I believe in no mere hospital treatment for these classes. I believe in the family practitioner who brings the children into the world and knows them and their parents and watches their health from year to year, their circumstances, their habits, even their bad habits, and treats them with consideration and kindly warning. An immense function of the medical profession lies in this direction and can only be discharged by a continuous family medical man whose observations may have much of a scientific character and add greatly to the influence of the profession. We have seen what has been done in the matter of acute and septic disease by the prodigious and pregnant discoveries of Pasteur and Lister who have stimulated a whole army of followers and imitators. There is another great field of work almost yet untilled and promising an abundant harvest to those who will study it with care—I mean the subject of what I may call degeneration as distinguished from disease. Much is being done to mitigate the mischief of acute diseases. But they do not make up the bulk of medical work. I went through one or two of my death-certificate books lately and took note of the causes of death in 100 cases. I found the average age of my patients at death was 63½ years, and that only 12½ per cent. of these died from acute diseases. The respectable age—the grand climacteric—attained by my clients may be due to special circumstances and I am sure is more to be explained by their good constitution than my skill or the composition of my medicines. But I should be sorry to think that we, I or any medical man, had nothing to do with adding to the longevity of our clients and that of their families—thinking, as I do, that our continuous care is of the very essence of medical service. In the great study of that is before the nation of the complicated causes of degeneration, the medical profession should bear a distinguished part, and there is no branch of the profession more able to advance this inquiry than the great body of general practitioners who, in so doing, will raise still higher the public estimate of the profession. Remember that Jenner began his study of the subject of vaccination while he was yet in practice in the country.

(4) *The competition of certificated midwives.*—Gentlemen, it was my duty as a member of the General Medical Council for 15 years to consider the question of the mischief done by ignorant and untrained midwives in the practice of their craft, which is as old as Genesis, and had come to be controlled in almost all other civilised countries of the world. I never hesitated as to the duty of the State to check and to control this pathetic and terrible evil and I think still as I did then. I must not detain you with the *pros* and *cons* of this controversy. But as I supported the demand for such legislation I have a special right and duty to protest against its defects. In all my action on this question I contemplated the midwife (and the whole Council did the same) as being trained for and acting

They consider that there are channels which afford communication between the three systems, but that they must be insignificant as the injection did not often pass from one to the other. We are not able to say whether the injection passes readily from the subserous layer to the submucous, but we find that the injection does pass readily from the submucous to the subserous, and that by inserting the needle into the submucosa all the vessels in the wall of the appendix can be injected. Further, Kelly and Hurdon state that only a limited area of the surface lymphatic plexus, representing the area draining into one collecting vessel, can be injected by one puncture. They say, "This demonstrates the existence of valves between the capillaries and the first system of collecting vessels and it demonstrates also the absence of valves in the capillaries a focus of infection inside such an area would therefore be practically isolated from the rest of the appendix." We have found no difficulty in injecting the entire subserous network of the appendix and even also of the apex of the cæcum from one puncture in the appendix. We believe, therefore, that there is not only free communication between the various systems of plexuses but also between one part of a plexus and another. We cannot entertain for a moment the idea that an infected area is isolated from the rest of the organ by the arrangement of its lymphatics. The plexuses of origin in the cæcum resemble in every respect those of the appendix.

The lymphatic vessels which issue from the appendix divide themselves into three sets. The first set consists of the vessels which drain the organ from its tip to near its root; the other two sets are formed by the vessels which arise from the root. The vessels forming the first set vary in number from eight to 15; leaving the wall of the appendix they enter the meso-appendix and ascend between its layers with the branches of the appendicular artery to its main stem around which they form a leash of from four to six vessels. These accompany the artery to its origin where they meet the lower group of the main ileo-colic chain.

FIG. 5.

Lymphatics of the cæcum and appendix. Posterior view.

Many of them end in the glands of this group; others, however, ascend to the glands of the upper group in which they end at variable levels. In some cases a gland in front of the duodenum is seen to be injected by vessels running directly from the appendix. When such vessels are traced to their origin we find that they may arise from any part of the appendix, and quite as frequently from its proximal as from its distal portion.

The appendicular gland when present receives vessels

from various parts of the appendix, from the apical portion as in Specimen C, from the body as in Specimen B, and from the root as in Specimen 30. In those cases where there is an accessory artery or arteries the lymph vessels from the proximal portion of the appendix accompany them and are received by the posterior ileo-colic glands. The vessels which drain the root of the appendix are arranged in anterior and posterior sets. The anterior vessels run from the appendix over the anterior surface of the cæcum and enter the ileo-colic fold. They invariably pass the glands here situated and end in members of the lower ileo-colic group. In some cases even this group may be passed, as is shown in Specimen 75, where vessels can be seen to thread their way among the lower group glands and to enter a gland of the upper group just below the duodenum. Posteriorly, vessels arise from the root of the organ and ascend over the posterior surface of the cæcum and in the cæcal attachment of the meso-appendix to the posterior ileo-colic glands. Some vessels, in this case also, are seen to pass this group without interruption to reach glands of the lower group of the main chain. Possibly the great number of glands in the ileo-colic corner may account for the fact that we have not seen in any instance a direct vessel of this set to the upper group. The vessels which drain the cæcum are simple in their arrangement. From the apex the vessels run with those of the root of the appendix and enter the same groups of glands; anteriorly they run in the ileo-colic fold to the lower group; posteriorly with the posterior ileo-colic vessels to the posterior ileo-colic glands and the lower main group. In one specimen, No. 87, a vessel issues from the muscular coat of the cæcum near the apex, descends on the appendix for a short distance, and then ascends with the appendicular vessels to a gland of the lower group at the origin of the artery. Tixier and Viannay³ describe a similar vessel in one of their specimens, but were unable to follow it to its gland. From the anterior surface of the body and base of the cæcum the vessels pass to the ileo-colic fold. Many of them enter the anterior ileo-colic glands, which appear to intercept in particular those vessels coming from the base of the cæcum and from the lower part of the colon. Some vessels, chiefly those from the lower part of the anterior wall, end in the lower main group and in some cases (Specimen 83) even in glands of the upper group. In one case (Specimen 74) one of these vessels turned backwards in the upper part of the ileo-colic fold and entered a posterior ileo-colic gland. From the posterior surface vessels run from the body and base of the cæcum to end in the posterior ileo-colic glands. Some vessels, however, pass these glands and end in the lower group of the main chain.

The vessels from the terminal portion of the ileum may be divided into three sets. The greater number of the vessels issuing from the last six inches of the small gut pass into the mesentery and end in the glands of the ileal group. But this is not the only path. If injection is made into the ileum as far out as six inches from the ileo-colic junction vessels will be seen to arise from the plexus, run to the right along the gut, to end in the anterior ileo-colic glands or in the lower main group. Another vessel pursuing a similar course along the free margin of the gut turns into the ileo-appendicular fold and enters the cæcal end of the meso-appendix, terminating in a gland of the posterior ileo-colic group. From the posterior surface of the extremity of the colon short vessels pass directly to the posterior ileo-colic glands. The vessels arising from the ascending colon pass transversely over the anterior and posterior surfaces of the gut and enter the numerous small glands which we have named the right colic glands. Here, as in the case of the vessels proceeding from other parts of the intestine, the glands do not intercept all the vessels; many pass inwards and end in the glands of the main chain.

The efferent vessels of the gland groups into which the lymphatics of the cæcum and appendix pass run as follows: those from the anterior ileo-colic glands enter the lower main group; in one specimen (63) vessels may be seen to end in the upper group. Those from the posterior ileo-colic group run to the lower group. In one specimen (N), an efferent from one of the posterior ileo-colic glands, injected from the back of the cæcum, passes upwards to a gland on the right colic artery. The efferents from the appendicular gland run to one of the glands of the lower group. Efferents from the lower group run to glands of the upper group, while the

³ Tixier and Viannay, *Lyon Medical*, 1901, No. 15, pp. 471-74.

of vessels should be considered together to insure, where possible, a common nomenclature. The ileo-colic artery arises from the superior mesenteric artery on the third part of the duodenum. At the lower border of the duodenum it leaves the root of the mesentery and proceeds downwards and outwards behind the parietal peritoneum towards the angle between the ileum and the ascending colon. At a distance of about an inch from the ileo-colic angle it breaks up into several branches—appendicular, anterior ileo-colic, posterior ileo-colic, ileal, and colic. At a variable distance from its origin it usually gives off the right colic artery, though this vessel may spring independently from the superior mesenteric trunk.

The terminal branches are inconstant in their mode of origin; usually the main artery gives off the appendicular and then divides into the anterior and posterior ileo-colic branches. The anterior branch gives off the ileal vessel, the posterior the colic. The appendicular artery descends in or near the free margin of the meso-appendix and terminates at the tip of the organ. It gives off branches, gradually decreasing in length, to the whole of the appendix. In many cases, however, one or more branches pass from the posterior ileo-colic artery to the proximal portion of the appendix. The ileal branch passes onwards in the mesentery to anastomose with the terminal portion of the superior mesenteric, and it supplies several inches of the ileum. The anterior ileo-colic descends in the ileo-colic fold and supplies the anterior surface of the cæcum, its terminal twigs reaching the root of the appendix; it also supplies a branch to the end of the ileum. The posterior ileo-colic descends behind the ileo-cæcal junction, supplying the back of the cæcum and the terminal portion of the ileum. As we have already noted, it often gives a branch or branches to the proximal portion of the appendix. The colic branch ascends along the inner side of the ascending colon and anastomoses with the right colic artery.

The following account of the lymphatic glands and vessels of the cæcum and appendix is based upon an examination of 25 specimens injected by the method of Gerota. The ileo-colic artery is surrounded from its origin to its division by a chain of lymphatic glands varying in number from 10 to 20, and in size from that of a pin's head to that of an almond. The chain is continuous, often without interspace, with the glands around the trunk of the superior mesenteric artery. Though the chain is frequently concatenate, it usually shows a tendency to fall into two groups, one lying on and below the lower border of the duodenum and the other above and around the point of division of the artery. For purposes of description it is of great convenience to divide the main ileo-colic chain into two groups, an upper group and a lower group. This division, as we have intimated, though frequently quite arbitrary, is not always so. The reasons which prompt us to make use of this subdivision will appear when the course of the lymphatic vessels coming from the cæcum and appendix is under consideration. It would be difficult to give an accurate description of these vessels without subdividing the main chain of glands.

At the point where the ileo-colic artery gives off its terminal branches the chain of glands becomes broken up into several groups which are associated with the branches of the artery. These groups are constant in position though not in the number of their constituent members, and are sufficiently distinct from each other to be described as separate groups; still they must be regarded merely as outlying portions of the main chain. Five groups may be described: (1) anterior ileo-colic; (2) posterior ileo-colic; (3) appendicular; (4) ileal; and (5) right colic.

The anterior ileo-colic glands vary in number from one to four, the usual number being three. They lie in the ileo-colic fold close to the wall of the cæcum; they may be continuous with the lower group of the main chain but it is more common to find an interval between them. The highest gland, which lies in the upper part of the fold just above the ileum, is almost invariably the largest. It is very unusual to find members of this group at a lower level than the lower margin of the ileo-cæcal junction.

The posterior ileo-colic glands are more numerous and less regularly disposed; this group is evidently the direct continuation of the main ileo-colic chain, and it is often impossible to mark the exact point of transition. The greater number of the glands lie in the angle between the ileum and the colon; some small glands are to be found lying in the groove between the cæcum and colon on the posterior surface of the cæcum and in about half the number of specimens we

have examined one or more project between the layers of the meso-appendix at its cæcal extremity.

FIG. 4.

Lymphatics of the cæcum and appendix. Anterior view.

The appendicular gland.—Between the layers of the meso-appendix at or near its free border a single small gland may sometimes be seen lying on the appendicular artery. (Specimens B, C, D, &c.) Its position on the artery is variable; it may lie some distance from the base of the meso-appendix or it may be quite close to its attachment. In one case (Specimen 30) it lay only partially between the layers of the fold. As the lower group of the main chain lies just above the attachment of the fold it seems evident that this gland is a prolapsed member of that group.

Ileal glands.—In the right end of the mesentery small glands lie in association with the ileal branch of the ileo-colic artery. They are most irregular in number and in size and only receive some of the vessels from the terminal portion of the ileum. As their efferents pass to the main ileo-colic chain we have regarded them as a subsidiary group of this chain.

The right colic glands, numerous but small in size, lie along the inner side of the ascending colon. They are in close contact with the wall of the colon, many of them being situated in the sulci in front of, and behind, the internal taenium. The lower ones are associated with the colic branch of the ileo-colic artery, the upper with the branches of the right colic artery. As their efferents terminate in the glands of the ileo-colic chain we speak of the whole row, from the cæcum to the hepatic flexure, as the right colic glands. Singularly few glands are to be encountered along the trunk of the right colic artery. In some of our specimens (A and N) we have seen one or two small glands, but in the majority none are to be found.

The plexuses of origin of the lymphatic vessels have been well described by various writers. We shall only briefly consider them in order to refer to some points of interest. According to Kelly and Hurdon¹ the lymphatic plexus of the appendix may be divided into three layers—superficial, middle, and deep—lying respectively under the peritoneum, under the circular muscular coat, and under the muscularis mucosæ. Each layer consists of a capillary plexus draining into larger collecting vessels which issue from the wall of the organ at the attachment of the meso-appendix.

¹ Kelly and Hurdon. The Vermiform Appendix and its Diseases, 1905.

and a gland in this fold. Lockwood supports these statements from clinical observations. Polrier and Cuneo formally deny the presence of such a communication and Polya and a Navratil have not been able to find it. We have never seen a trace of this communication in any of our specimens, and we do not believe that it exists. Kelly and Hurdon suggest that there is such a communication between the lymphatics of the appendix and those of the ovary by means of the subperitoneal lymphatic plexus which exists everywhere in that tissue, but they have been unable to find lymphatic vessels running from the appendix in the appendiculo-ovarian fold. Comparatively little attention has been given to the vessels of the cæcum in the past. This may be due to the fact that this organ is far more difficult to inject than any other part of the intestine. Most writers simply state that the vessels of the cæcum run to the neighbouring glands. We would emphasise what has been already stated, that while the majority of the vessels from the body and base of the cæcum are intercepted by the anterior and posterior ileo-colic glands, some of these, together with those of the apex of the organ, frequently pass beyond these glands to high glands of the ileo-colic chain, that vessels of the cæcum may ascend to the meso-appendix, and that they freely communicate with the vessels of the appendix.

We have now to consider the practical importance of the information we have derived on the lymphatic system of the cæcum and appendix. We find here a large agglomeration of lymphatic glandular tissue devoted to a comparatively small portion of the alimentary canal. It is evident that this mass of glands is of great importance and that its defensive powers will frequently be called upon. The changes which may take place in the glands of the ileo-colic chain as a result of disease are of the greatest practical importance. Acute inflammation may occur as a result of infection from the appendix in cases of appendicitis, or from the cæcum in rare cases of typhilitic ulceration; tuberculosis is met with not infrequently, and the glands may be invaded by secondary deposits in cases of malignant growth of the cæcum and appendix. Acute inflammation of the glands of the ileo-colic chain in cases of appendicitis is possibly more common than is generally recognised, although it is rare for suppuration to occur. Quenu¹¹ states that it is common in cases of fulminating appendicitis to find the glands of the chain enlarged and inflamed and he believes that the presence of a tender area reaching from the right iliac fossa upwards and towards the middle line is an indication of glandular inflammation and affords some guidance as to the severity of the infection. If it were possible during operations for acute appendicitis to ascertain the condition of the glands of the ileo-colic chain it is likely that they would frequently be found in the condition described by Quenu. Few cases have been recorded in which suppuration of these glands has occurred. Ricard¹² reports a case in which an operation was performed for acute appendicitis. The patient left the hospital apparently well but returned with acute symptoms necessitating a re-opening of the abdomen. Ricard found a chain of infected glands, some of which were full of pus. They were extirpated with a good result. Bloodgood¹³ describes a rare case of appendicitic abscess situated between the layers of the mesentery. The patient was a child; "one could palpate in the middle zone of the abdomen, a mass about the size of two fists slightly moveable from right to left but not from above down (on opening the abdomen) beginning at the cæcum and extending at least to the third lumbar vertebra between the folds of the mesentery there was a mass on separating the exudate at the junction of the ileum and cæcum pus was encountered and a large abscess cavity was found extending towards the vertebral column between the folds of the mesentery." On careful consideration of this case it is difficult to avoid the conclusion that the abscess was due to suppuration of the glands of the ileo-colic chain.

In view of the frequency of appendicitis the comparative rarity of glandular suppuration is somewhat surprising. Cornier¹⁴ suggests that it is due to the fact that the glands become tolerant and inured to the products of bacterial action, so that they are very rarely excited to the pitch of suppuration. It is possible that glandular abscesses are frequently overlooked; for example, an abscess originating

in the posterior ileo-colic glands may easily be opened during the course of the operation without any suspicion of its nature being aroused. It must be remembered in this connexion that, as we have already shown, lymph vessels run directly from the appendix to any gland, even the highest, of the ileo-colic chain, and that there is therefore no reason why the highest gland should not become infected and suppurate just as readily as the lowest. It is conceivable, therefore, that a glandular abscess, due to infection from the appendix, might form in front of the third part of the duodenum.

The ileo-colic chain of glands is frequently affected by tuberculosis. It is common enough in children suffering from abdominal tuberculosis to feel a mass of enlarged glands in this situation, and on examination of these glands in a series of necropsies they frequently show signs of previous disease. Corner¹⁵ describes the case of a boy who had a well-defined mass in the region of the cæcum of about the size of a cricket ball. On opening the abdomen the omentum was found adherent to the mass. "After gradually stripping this off a large rounded mass was found lying in the mesentery, adherent to the cæcum, the ascending colon, and partly to the transverse colon. During manipulation a weak spot in the wall of the swelling gave way, tuberculous caseous pus escaping the cavity extended upwards and inwards towards the root of the mesentery." The cavity was cleaned and obliterated by suture, recovery ensuing. Gerard Marchant¹⁶ reports two cases in which he had treated diseased glands in this region by operation. In one case during the removal of the appendix it was found that there was a mass formed by two caseous glands, apparently in the ileo-colic fold. They were enucleated with ease. In a second case during an operation for appendicitis a mass of enlarged glands was found on the anterior surface of the cæcum; these were curetted and cauterised. In the majority of cases the affection of these glands will be merely an incident in a general tuberculosis of the mesenteric glands. Should operative treatment become necessary the intimate relation of this glandular chain to the ileo-colic artery and vein must be borne in mind; if these vessels are damaged by a too vigorous attempt to remove the diseased glands the vitality of a considerable portion of the intestine will be endangered.

It is in connexion with malignant disease of the cæcum and appendix that the exact anatomy of these lymphatic vessels and glands becomes of the greatest importance. Indeed, it is extraordinary how little attention has been directed to this question in the past. It may be partially explained by the fact that the attention of surgeons has been so much bestowed on the perfection of the mechanical means of restoring the continuity of the intestinal canal after a malignant growth has been removed that the possibility of removing the lymphatics at the same time has received little attention. Another factor which has militated against any serious attempt to remove the lymphatic apparatus in connexion with the cæcum is the fear always present in the mind of the surgeon who is removing a portion of intestine of interfering with the blood-supply of the intestine at the suture line. Furthermore, it is an accepted doctrine that glandular infection does not occur in the early stages of malignant disease of the intestine; whether this doctrine is worthy of the belief which has been accorded it in the past is open to question. To illustrate the methods usually adopted at the present time in dealing with the glands in cases of carcinoma of the cæcum a quotation may be given from one of the most recent and complete works on abdominal surgery. Moynihan,¹⁷ in his description of the operation of excision of the cæcum, after giving the preliminary steps, says: "The ascending colon must then be freed from the posterior abdominal wall to which it is often adherent. For this purpose the parietal peritoneum to the outer side of the colon is incised and raised up towards the colon. The stripping must be continued towards the middle line, behind the termination of the enteric mesentery, so that any enlarged glands—and of these there may be many—are made free also as a general rule the tumour mass will by this means be rendered sufficiently mobile to permit of its easy withdrawal from the abdomen in some few instances, however, owing to the density of the adhesions, or the shortness of the enteric mesentery, or to the enlargement of glands this may

effluents of the upper group pass to the glands around the trunk of the superior mesenteric artery.

The anatomy of the lymphatics of the cæcum and appendix has been much obscured by an unnecessary subdivision of gland groups and by a redundant nomenclature. Poirier and Cunéo⁴ describe three groups of glands lying in the meso-appendix; they term these the retro-ileal, the sub-ileal, and the juxta-cæcal appendicular glands. Olado in his classic memoir⁵ attaches prime importance to a gland situated in the base of the meso-appendix close to the cæcum; this gland he considers to be the chief recipient of the vessels of the appendix. This view was supported by Lafforgue,⁶ who gives tables showing the number and frequency of occurrence of the glands in the meso-appendix. These descriptions limit the attention to the glands near the appendix; in the paper by Tixier and Viannay⁷ we have another illustration of this contracted view of the lymphatics of the appendix in this remark: "Lafforgue, who has studied the glands of the appendix, has well shown that this organ is often furnished with more than one gland." They proceed to show that the lymphatic vessels of the appendix drain into three groups of glands, cæco-appendicular glands lying in the outer angle of the meso-appendix, ileo-appendicular at its inner angle, and meso-appendicular glands lying between these; all these groups are inconstant in presence and number. They advance a step in pointing out that there is more than one lymphatic current from the appendix.

By far the most complete and satisfactory description is that given by Polya and von Navratil⁸ from the study of 13 injected specimens. This paper seems to have escaped general notice, as it is never quoted, and it did not come within our knowledge until our own work was well advanced. In the main our observations agree with theirs, but they are able to quote only one case in which lymphatic vessels from the appendix pass to the higher glands of the ileo-colic chain. Kelly and Hurdon⁹ gave an elaborate account of the lymphatic plexuses, vessels, and glands of the appendix. In the main their description agrees with that of Poirier and Cunéo, but they describe four types of lymphatic circulation from the appendix. We have purposely avoided any classification into types because there is such variety in the arrangement of the vessels and distal glands that it would be possible to multiply the types to any extent and their enumeration would merely obscure the main and important points. The subdivision of the glands into small groups with the consequent increase in the number of names leads to great confusion, of which we find numerous examples in the literature. The gland described by Olado, lying in the outer angle of the meso-appendix, is commonly placed by other authors in the inner angle. In all these descriptions too much importance is attached, perhaps unwittingly, to the glands in the meso-appendix. The specimens from which our description is made show that the glands in the meso-appendix are merely prolapsed members of the posterior ileo-colic gland group and of the lower group of the main ileo-colic chain. The gland which we have termed "appendicular," lying in or near the free border of the meso-appendix, is met with at various levels, sometimes only projecting between the layers at their attachment, sometimes just below the attachment, and sometimes a considerable distance below. When the specimens are compared it becomes very evident that the gland is merely one of the lower group glands. Similarly, the gland or glands which are sometimes found in the upper outer angle of the meso-appendix close to the cæcum are really members of the posterior ileo-colic group; consequently this gland, or glands, on which so much stress is laid by Olado and others, is always present, but does not always lie in the meso-appendix. The group certainly does not require a special name. But the presence or absence of glands in the meso-appendix is a matter of the slightest importance, in view of the fact that these glands even when present do not intercept more than a few of the appendicular lymphatics. It is of importance, and it is the point to which we wish to draw attention, that

lymphatic vessels from any part of the appendix, root, body, or tip, run past the glands in the vicinity of the organ to glands of the main ileo-colic chain, reaching even those members of the upper group which lie on the duodenum. On this point we were entirely uninformed by previous descriptions and it is of great importance to recognise the fact that practically any gland of the ileo-colic chain, from its upper to its lower end, may be a primary gland for the appendicular vessels.

FIG. 6.

Lymphatics of the cæcum and appendix. Two appendicular arteries are present with lymphatic vessels accompanying each.

The account of the lymphatic system of the appendix given by Lockwood differs materially from that of other authors. He says: "I have so frequently found a chain (of glands) along the inner side of the right colon behind the ascending meso-colon, that I have come to the conclusion that this is the course which the appendicular lymphatics mainly pursue. Others without doubt open into the mesenteric glands."¹⁰ There is also a statement to the effect that the lymphatics of the appendix form connexions with the chain of glands lying close to the common and external iliac arteries. In a footnote Lockwood maintains his position against the criticisms of Poirier and Cunéo and of Kelly and Hurdon. We have found in all our specimens the numerous glands which lie along the inner side of the ascending colon and we conclude that these are the glands referred to. But these glands, the right colic glands, drain the colon and have nothing to do with the cæcum and appendix. Some of our specimens (Nos. 55 and 83) show that the main ileo-colic chain may lie close to the ascending colon and it is quite possible that in cases of appendicitis, from which Mr. Lockwood's observations were made, when the glands are perhaps considerably enlarged and when the ascending colon is distended, they may appear to lie in the position described by him. It seems probable that the chain of glands which he has observed is really the ileo-colic chain and is not formed by the right colic glands; we find in his description strong confirmation of our contention that in diseases of the appendix this chain in its entirety may be affected. We have not met with any communication between the lymphatics of the cæcum and appendix and the glands lying along the common and external iliac arteries. A great deal of attention has been directed to the statement of Olado that there is a communication between the lymphatics of the appendix and those of the ovary and uterus, in the so-called appendiculo-ovarian fold. Olado states that he found this communication in two injected specimens. Tixier and Viannay in one case

found a gland in this fold. Lockwood supports these statements from clinical observations. Poirier and Caneco formally deny the presence of such a communication and Polya and von Naxrath have not been able to find it. We have never seen a trace of this communication in any of our specimens, and we do not believe that it exists. Kelly and Hurdon suggest that there is such a communication between the lymphatics of the appendix and those of the ovary by means of the subperitoneal lymphatic plexus which exists everywhere in that tissue, but they have been unable to find lymphatic vessels running from the appendix in the appendiculo-ovarian fold. Comparatively little attention has been given to the vessels of the cæcum in the past. This may be due to the fact that this organ is far more difficult to inject than any other part of the intestine. Most writers simply state that the vessels from the cæcum run to the neighbouring glands. We would emphasise what has been already stated, that while the majority of the vessels from the body and base of the cæcum are intercepted by the anterior and posterior ileo-colic glands, some of these, together with those of the apex of the organ, frequently pass beyond these glands to high glands of the ileo-colic chain, that vessels of the cæcum may ascend in the meso-appendix, and that they freely communicate with the vessels of the appendix.

We have now to consider the practical importance of the information we have derived on the lymphatic system of the cæcum and appendix. We find here a large agglomeration of lymphatic glandular tissue devoted to a comparatively small portion of the alimentary canal. It is evident that this mass of glands is of great importance and that its defensive powers will frequently be called upon. The changes which may take place in the glands of the ileo-colic chain as a result of disease are of the greatest practical importance. Acute inflammation may occur as a result of infection from the appendix in cases of appendicitis, or from the cæcum in rare cases of typhlitic ulceration; tuberculosis is met with not infrequently, and the glands may be invaded by secondary deposits in cases of malignant growth of the cæcum and appendix. Acute inflammation of the glands of the ileo-colic chain in cases of appendicitis is possibly more common than is generally recognised, although it is rare for suppuration to occur. Quenu¹¹ states that it is common in cases of fulminating appendicitis to find the glands of the chain enlarged and inflamed and he believes that the presence of a tender area reaching from the right iliac fossa upwards and inwards towards the middle line is an indication of glandular inflammation and affords some guidance as to the severity of the infection. If it were possible during operations for acute appendicitis to ascertain the condition of the glands of the ileo-colic chain it is likely that they would frequently be found in the condition described by Quenu. Few cases have been recorded in which suppuration of these glands has occurred. Ricard¹² reports a case in which an operation was performed for acute appendicitis. The patient left the hospital apparently well but returned with acute symptoms necessitating a re-opening of the abdomen. Ricard found a chain of infected glands, some of which were full of pus. They were extirpated with a good result. Bloodgood¹³ describes a rare case of appendicitis abscess situated between the layers of the mesentery. The patient was a child; "one could palpate in the middle zone of the abdomen, a mass about the size of two fists slightly movable from right to left but not from above down (on opening the abdomen) beginning at the cæcum and extending at least to the third lumbar vertebra between the folds of the mesentery there was a mass on separating the exudate at the junction of the ileum and cæcum pus was encountered and a large abscess cavity was found extending towards the vertebral column between the folds of the mesentery." On careful consideration of this case it is difficult to avoid the conclusion that the abscess was due to suppuration of the glands of the ileo-colic chain.

In view of the frequency of appendicitis the comparative rarity of glandular suppuration is somewhat surprising. Corner¹⁴ suggests that it is due to the fact that the glands become tolerant and inured to the products of bacterial action, so that they are very rarely excited to the pitch of suppuration. It is possible that glandular abscesses are frequently overlooked; for example, an abscess originating

in the posterior ileo-colic glands may easily be opened during the course of the operation without any suspicion of its nature being aroused. It must be remembered in this connexion that, as we have already shown, lymph vessels run directly from the appendix to any gland, even the highest, of the ileo-colic chain, and that there is therefore no reason why the highest gland should not become infected and suppurate just as readily as the lowest. It is conceivable, therefore, that a glandular abscess, due to infection from the appendix, might form in front of the third part of the duodenum.

The ileo-colic chain of glands is frequently affected by tuberculosis. It is common enough in children suffering from abdominal tuberculosis to feel a mass of enlarged glands in this situation, and on examination of these glands in a series of necropsies they frequently show signs of previous disease. Corner¹⁵ describes the case of a boy who had a well-defined mass in the region of the cæcum of about the size of a cricket ball. On opening the abdomen the omentum was found adherent to the mass. "After gradually stripping this off a large rounded mass was found lying in the mesentery, adherent to the cæcum, the ascending colon, and partly to the transverse colon. During manipulation a weak spot in the wall of the swelling gave way, tuberculous caseous pus escaping the cavity extended upwards and inwards towards the root of the mesentery." The cavity was cleaned and obliterated by suture, recovery ensuing. Gerard Marchant¹⁶ reports two cases in which he had treated diseased glands in this region by operation. In one case during the removal of the appendix it was found that there was a mass formed by two caseous glands, apparently in the ileo-colic fold. They were enucleated with ease. In a second case during an operation for appendicitis a mass of enlarged glands was found on the anterior surface of the cæcum; these were curetted and cauterised. In the majority of cases the affection of these glands will be merely an incident in a general tuberculosis of the mesenteric glands. Should operative treatment become necessary the intimate relation of this glandular chain to the ileo-colic artery and vein must be borne in mind; if these vessels are damaged by a too vigorous attempt to remove the diseased glands the vitality of a considerable portion of the intestine will be endangered.

It is in connexion with malignant disease of the cæcum and appendix that the exact anatomy of these lymphatic vessels and glands becomes of the greatest importance. Indeed, it is extraordinary how little attention has been directed to this question in the past. It may be partially explained by the fact that the attention of surgeons has been so much bestowed on the perfection of the mechanical means of restoring the continuity of the intestinal canal after a malignant growth has been removed that the possibility of removing the lymphatics at the same time has received little attention. Another factor which has militated against any serious attempt to remove the lymphatic apparatus in connexion with the cæcum is the fear always present in the mind of the surgeon who is removing a portion of intestine of interfering with the blood-supply of the intestine at the suture line. Furthermore, it is an accepted doctrine that glandular infection does not occur in the early stages of malignant disease of the intestine; whether this doctrine is worthy of the belief which has been accorded it in the past is open to question. To illustrate the methods usually adopted at the present time in dealing with the glands in cases of carcinoma of the cæcum a quotation may be given from one of the most recent and complete works on abdominal surgery. Moynihan¹⁷ in his description of the operation of excision of the cæcum, after giving the preliminary steps, says: "The ascending colon must then be freed from the posterior abdominal wall to which it is often adherent. For this purpose the parietal peritoneum to the outer side of the colon is incised and raised up towards the colon. The stripping must be continued towards the middle line, behind the termination of the enteric mesentery, so that any enlarged glands—and of these there may be many—are made free also as a general rule the tumour mass will by this means be rendered sufficiently mobile to permit of its easy withdrawal from the abdomen in some few instances, however, owing to the density of the adhesions, or the shortness of the enteric mesentery, or to the enlargement of glands this may

not be possible. In such circumstances the mesentery is tied off in sections and divided on the proximal side of the enlarged glands." It will be seen that although any palpably enlarged glands are removed by this method no attempt is made to deal with a possibly infected lymphatic area.

A method of removing a growth of the cæcum or ascending colon has recently been published by F. S. Bird.¹³ His description of the operation is as follows:—

The tumour is located and its removal being decided on the transverse colon is pulled down, two forceps are applied to it close together, a heavy one on the proximal side, and the gut is divided with large scissors in one cut. Swabs are used to avoid soiling the cavity, and the heavy forceps attached to the gut is allowed to hang out of the wound, a proceeding which puts the mesocolon on the stretch. The branches of the middle colic artery are easily found, for they stand out by reason of the tension and the fact that they are the thickened arteries of an elderly person. Two or three branches have to be secured. The right colic artery now invites attention and can readily be tied far back by a single ligature; this devascularises a large portion of meso-colon, which can be speedily severed by large scissors. The amount of gut at present hanging out of the wound is considerable, as the cæcum "is in the air" without support. The resulting traction shows the ileo-colic trunk in strong salience. Forceps are then placed on the ileum, about four inches from the junction of the great and small intestine, and the gut is divided; the distal end now depends from the wound, so that the whole portion to be resected is hanging by the ileo-colic artery and some peritoneum. This blood-vessel is ligatured far back, the isthmus of tissue left is divided close to it, and the resected gut, two forceps, and the ileo-colic glands fall out of the wound altogether. There is no need to investigate the important ileo-colic lymphatic area, for it has gone.

By this operation Bird appears to secure some of the lower glands, the anterior and posterior ileo-colic groups, but it is evident from the fact that he secures the right colic and the ileo-colic arteries separately, that the important glands of the main ileo-colic chain are not removed.

Considerable permanent success has, however, attended the removal of malignant growths of the intestine, on these lines. In the case of carcinoma of the sigmoid colon, this may be easily understood; these growths are usually of the constricting variety; they produce obstruction of the intestine, in the majority of cases, long before any tumour is palpable and at a comparatively early stage of the disease. Surgical interference becomes necessary for the relief of the obstruction; the condition is recognised and, in favourable cases, the growth may be removed while still in an early stage and probably before glandular infection has taken place. In the case of malignant growths of the cæcum and ascending colon it is a different matter; such growths are almost always recognised as palpable tumours before they have produced symptoms of intestinal obstruction of such severity that operative treatment is imperative. That is to say, they have reached a later stage and are much more likely to have given rise to glandular infection at the time the condition is recognised. It is impossible for us to bring forward any figures demonstrating the frequency of glandular metastasis in cases of malignant disease of the cæcum and ascending colon, or of the extent of the glandular affection. Such cases as we are referring to are comparatively rare; a record of the history after operation of a number of cases would be very difficult to obtain, and even if we were possessed of such a record it would be impossible to say what proportion of the recurrences was due to persistence of the disease in the lymphatic glands and what proportion was due to liver metastasis already present at the time of removal of the primary growth and what to local recurrence.

Text-books have little to say on the subject of lymphatic infection in cases of cancer of the intestine. It is well known that it does occur but of its frequency and extent we know little. It must be remembered that, as we have shown, lymphatic vessels having their origin in the cæcum and colon pass directly not only to the subsidiary gland groups of the ileo-colic chain but even to the lower and upper groups of that chain. This is particularly well seen in Specimen 83, where a vessel arising on the anterior surface of the cæcum is seen running in the ileo-colic fold, past the glands there situated, past the lower group of the main chain, to end in a gland of the upper group. This condition is not so frequent in the case of the caecal lymphatics as in those of the appendix, but it does occur and account must be taken of its occurrence. It is obvious, therefore, that if infection of the glands takes place by a process of embolism, the lower glands of the main chain, and even the upper glands are just as likely to become infected, and that as early in the course of the disease as are the glands in close relation to the cæcum.

In operating for malignant disease, if any attempt is

made to remove glands which are possibly infected, the upper glands of the ileo-colic chain must receive attention. It seems advisable, therefore, in these cases to apply those principles which have been found so successful in the treatment of malignant disease of other organs—viz., to remove not only the organ containing the primary growth but the lymphatic glands receiving vessels from it, the vessels themselves, and the tissues in which these vessels lie. This can be done without a doubt; indeed, there is in the whole body no organ which is so happily placed as the cæcum in this respect; it is possible to remove all the glands receiving vessels from the cæcum and all the vessels, without leaving any subsidiary channels untouched, as must be done in the case of other organs, such as the breast. And this without any very serious extension of the operation usually practised—indeed, with considerable gain, the more radical operation giving a far better control over the blood supply and enabling the surgeon to recognise and avoid important structures which may be wounded and have frequently been wounded in the past. In cases suitable for radical treatment the operation which is suggested by the arrangement of the lymphatics is as follows. After opening the abdomen and exposing the field of operation the lower border of the third part of the duodenum is defined. The peritoneum over this is divided for a short distance and careful search is made for the ileo-colic vessels. The fatty tissue surrounding the vessels, which will contain the uppermost gland of the ileo-colic chain, is pushed downwards and the vessels cleaned by gauze stripping. At this stage the greatest possible care must be taken not to wound the duodenum. The artery and vein are then ligatured in two places and divided, the point of division of the artery being about half an inch from the superior mesenteric trunk. This step will devascularise the whole of the ascending colon, and it is well at this stage to select the point on the colon, at the hepatic flexure or, if an excessive amount of contraction of the colon has been caused by the growth, on the transverse colon, where the gut shall be divided. The peritoneum is then divided from the duodenum to the selected point on the colon, but the section of the gut is deferred until towards the end of the operation. In doing this it will be necessary to secure some branches of the middle colic artery, and if the right colic artery has a separate origin from the superior mesenteric it will also need attention. The peritoneum of the anterior layer of the mesentery is then divided in a line reaching obliquely downwards to the ileum. The ileo-colic and right colic vessels, with the accompanying chain of glands, the fatty tissue, and the overlying peritoneum, are then stripped downwards to the ileum and cæcum and outwards to the colon. In doing this the ureter will be encountered and must be carefully avoided. The cæcum is then lifted up and the peritoneal reflection from it and from the outer side of the colon on to the posterior abdominal wall is divided; a portion of the posterior layer of the mesentery of the small intestine will also require section.

The cæcum and appendix, the whole of the ascending colon, and the terminal portion of the ileum, with the ileo-colic and right colic vessels and the accompanying lymphatic chain, can then be withdrawn from the abdomen, only remaining attached by the continuity of the intestine. At the previously selected point the colon is divided. Some care is needed in determining the point at which the ileum is to be cut through. The terminal portion is supplied by an arcade formed by the ileal branch of the ileo-colic artery and the terminal portion of the superior mesenteric artery. In order to obtain a sufficient blood supply to the ileum at the point of section it is necessary to divide it at some distance (about six inches) from the ileo-caecal valve at about the point where the last part of the superior mesenteric artery runs downwards in the mesentery. If it is divided too close to its termination the blood supply of the cut end will be endangered owing to the removal of the ileo-colic artery.

It is not within the scope of this paper to discuss the various methods of restoring the continuity of the intestinal canal after a portion has been removed. A satisfactory canal after a portion has been removed. A satisfactory method of completing the operation will be to close the ends of both ileum and colon, to draw the termination of the ileum up to the transverse colon, and to effect a lateral anastomosis between the two. In this way the mesentery will be drawn over the raw area on the posterior wall of the abdomen and may be held in position by a few points of suture through the peritoneum. The question naturally

arises. Is it necessary to perform this formidable operation in cases of malignant disease of the appendix? If an undoubted malignant growth of the appendix is found, particularly if it extends on to the caecum, then it certainly would be advisable to do so. A study of recorded cases demonstrates the fact that frequently the condition has not been suspected until a microscopical examination of the appendix, which has usually been removed for recurrent attacks of appendicitis, has been made. In such cases the extensive operation is probably unnecessary.

A SERIES OF CASES OF GOITRES REMOVED UNDER COCAINE ANÆSTHESIA.¹

By J. LYNN THOMAS, O.B., F.R.O.S. ENG.,

HONORARY SURGEON TO THE CARDIFF INFIRMARY AND THE HARADRYAD HOSPITAL, ETC.

ORDINARY goitres are fairly common throughout Wales and Monmouthshire, and in some counties they occur with great frequency, whilst in three counties—viz., Pembroke, Carnarvon, and Anglesea—they are rarely met with. Two years ago Dr. William Williams, medical officer of health of the county of Glamorgan, and I sent a circular letter with questions relating to the prevalence of goitre to every medical practitioner within the above areas and we received replies from 231. We have not yet completed our investigations, but I am allowed to make use of some of the facts that we gleaned from this inquiry. There are many districts where goitres are very prevalent and few in which they are absent. With regard to the causation of ordinary goitres, the opinion of medical practitioners who have observed the rapid transformation of the sparsely populated rural districts of Glamorgan and Monmouth to the present densely populated condition is of great importance and value. For example, Dr. T. Hall Redwood of Rhymney states that 30 years ago ordinary goitres were common in his practice, but since the construction of the new waterworks they have practically disappeared. Similar views have been received from others practising in the county of Glamorgan. The following extract from a letter I received from Mr. —, upon whom I operated for goitre in July, 1903, is of interest in connexion with what seems to me to be the effect of change of water-supply upon the development of goitre. He says: "I am one of six children; the first four were born near Aberystwyth and the other two were born after my parents removed to Glamorganshire, where they obtained drinking water from a deep well in the garden. 1. My eldest sister was ten years old when we came to Glamorgan and a few years after she had a goitre and was an invalid on that account for seven years, before the late Mr. Greig Smith operated upon her in October, 1895, and was under treatment for some months afterwards. 2. My eldest brother was eight years of age when he came to Glamorgan, and before he was 12 years of age developed a goitre, and was operated upon by Sir Frederick Treves in November, 1893, at the London Hospital. He lost his voice for three months and eventually recovered it completely. 3. I came to Glamorgan when six years old and a goitre appeared when about 10 to 12. It grew steadily until it was removed by yourself when I spent the first week of my summer holidays of 1903 at your private hospital, and have been well ever since. 4. Next brother, free from goitre, and went to Leatherhead to school when 10 years of age. 5. Sister, had goitre, noticed when 19 years of age. 6. Sister, had no goitre, and went to school at Bristol."

The eldest three of the above family developed goitres within a few years after going to their new home, and the two boys showed symptoms between 10 and 12 years of age. The younger members of the family spent more time away from their home and the absence of goitre is ascribed to this fact by my correspondent. I have known a lady from a non-goitrous district go to reside in Derbyshire for two years and to return with a well-marked goitre; she was treated by injection of perchloride of iron at great risk to her life and with permanently ugly scarring of the neck. All the above facts support the view that goitres can be acquired

fairly quickly by living in a goitre-producing district and as far as I can judge from analysis of the evidence collected, the distribution of goitres in Wales and Monmouthshire supports the view that the causation of this disease is to be found in drinking water. For example, I would instance parts of the counties of Cardigan, Carmarthen, and Pembrokeshire, which form a smooth undulating plateau with rounded hillocks and gently hollowed valleys. There is total absence of prominent rugged escarpments or precipitous hillsides or narrow valleys running in east and west or north and south or any other preponderating direction. I know of goitres developing in this district in people who have spent their whole life on the top of the hills, as well as in those who have always resided in the lowest part of the valley.

Diagnosis.—In the majority of cases there is no difficulty in recognising the character of a goitre in the neck, but in a case of symmetrical lipoma of the neck in a woman, aged 62 years, I did not suspect its character until operation for its removal was done. The lipoma had none of the ordinary attachments to the skin and moved up and down with deglutition. In intrathoracic goitres and in those which are partly within and partly without the thorax—"the diver" type—Professor Kocher has demonstrated the value of examination by the fluorescent screen in determining whether operation is practicable by observing the mobility of the lower border of the intrathoracic shadow of the goitre.

[Mr. Lynn Thomas here exhibited photographs of the different types of goitres. 1. Symmetrical enlargements of the lateral lobes of the thyroid gland (it weighed three and a half pounds after removal). 2. Enlargement of one lobe. 3. "The diver" type of goitre (Kocher). The isthmus and the left lobe were enlarged. Cyanosis, dyspnoea, and dysphagia existed and when the head was bent forward the goitre was well within the thorax. It was a difficult case and trying to the patient when the intrathoracic portion was delivered. The late Alderman Dr. Naunton Davies was present and said that the operation reminded him of the pre-anæsthetic days. 4. Malignant goitre with enlarged glands on the right side. 5. Goitre of isthmus photographed six days after operation.]

Treatment.—The number of operations that I have performed are as follows:—

No mor-	55, under local anæsthesia (cocaine, 1 per cent.), including 4
tality.	Graves's disease.
	1 without any anæsthesia.
	17 under general anæsthesia, including 5 Graves's disease.
	1 death from respiratory complications } Graves's.
	1 " " hyperthyroidism }
	1 " " sepsis (one of my early cases).

Another case of Graves's disease died suddenly and without any warning in the operation theatre before anything was done. I had had the patient under observation at the Cardiff Infirmary for some weeks; during that time I fully explained to her that the nature of the operation was only ligature of an artery, and apparently I enjoyed her full confidence. After she was carried into the operation-room she chatted with me quite pleasantly and I left her for a few minutes to get ready for the operation when she expired quite suddenly, without any warning, before I returned. Had I injected cocaine subcutaneously, or even manipulated her neck, I could find a plausible explanation for the cause of death.

The case in which I used no local anæsthesia was due to my hypodermic syringe breaking after Kocher's screen had been fixed round the patient's neck and the preliminary marking of the skin incision had been completed. As this accident meant abandoning the operation I decided to proceed at once by telling the patient that the chief pain she would suffer would be from insertion of the needle. She stood the operation very well and next day when I was removing the drainage-tube and skin sutures she told me that the worst pain she felt was during the injection of the cocaine, which in the circumstances meant incision of the skin.

I always use Kocher's "collar incision" whenever possible as it gives ample room and exposes the blood-vessels at right angles to their course and leaves a scar which is scarcely perceptible. When Professor Kocher was the guest of the Cardiff Medical Society last year I took the opportunity of expressing my appreciation of his method and of pointing out that the description of the scar left by the "collar incision" had been described in Wales over 1000 years ago—in legend. We are told that St. Winifred had her head severed from her body, and that St. Beuno performed the operation

¹ A paper read before the Medical Society of London on April 2nd 1907.

of restoring it to its former position in such a skilful manner "that not even a scar was left, but only a thin white thread-line encircled her beautiful neck as evidence of the miracle of the seventh century."

During the last two years I have adopted Dr. Albert Kocher's¹ suggestion of placing the patient in the position shown in the illustration (Fig. 1). This position makes a

FIG. 1.

Kocher's position.

great difference in the amount of oozing and of engorgement of the veins and renders the operation much easier. In large goitres requiring long incisions I mark the skin at right angles to the "collar incision" in two or three places according to requirements, and these serve as landmarks for accurately re-uniting the divided platysma myoides subcutaneously. (Fig. 2.) About one hour before operation the

FIG. 2.

The collar incision. x shows the guide marks.

patient's neck is shaved in order to remove the downy hair and surface organisms and is then thoroughly cleansed with ether-soap and spirit, and a protective covering soaked in a 5 per cent. carbolic lotion is put on until the operation is commenced. The hair bordering on the neck is well brushed with carbolic lotion and the head is covered with a sterile rubber cap. The patient's knees are strapped to the table and the hands are placed at the side in suitable bags which are tied together under the back. Then Kocher's screen for neck operations is fixed so that the risk of contamination of the wound from accidental vomiting, &c., is obviated and the patient cannot see anything or anyone concerned with the operation. The patient is then covered with suitable sterile sheets and the surgeon and his assistant wear dry sterile thread gloves; then the neck is marked by

drawing the edge of the scalpel very lightly round it in the position which later forms the collar incision; by this manoeuvre no pain is inflicted but sufficient blood exudes to form a thin red line under which from one to two drachms of a 1 per cent solution of cocaine are injected by means of Kocher's syringe from end to end so as to form a continuous subcutaneous ridge. As soon as the injection of cocaine is completed the collar incision is made at once and the upper flap is first dissected upwards and consists of skin, subcutaneous tissue, platysma myoides, and the fascia covering the anterior surface of the neck muscles. Every blood-vessel exposed is first clamped by two Kocher forceps and divided between them so that the amount of blood lost is a mere trifle. The lower flap is then formed.

In certain cases it is necessary to divide the sterno-hyoid and sterno-thyroid muscles in order to facilitate the delivery of the goitre; in order to prevent atrophy of these muscles they must be divided near their upper or lower ends according to the exigencies arising, and by so doing the nerve supply to the muscles will not be interfered with. In order that the condition of the neck should be restored as nearly as possible to its normal appearance, and also that the resulting scar should approximate in its cosmetic effect that reputed to have been the case in that of St. Winifred, one must endeavour in the first place to restore to their normal conditions every divided muscle by carefully re-uniting the ends, and in the next place to sew the skin together by means of a very fine needle to avoid puncture scars, and lastly the drainage tube must be removed at the expiration of from 18 to 24 hours, together with the skin sutures. Special attention must also be given to accurate apposition of the edges of the aperture left by the removal of the drainage-tube, otherwise slight puckering will take place. When cases require a large number of ligatures, from 30 to 100, I use a little finger reel (carrying silk No. 00) which I devised for the purpose. Fig. 3 shows

FIG. 3.

The reel.

the method of attaching it on the little finger of the left hand when in use. It is made by Messrs Weiss and Son. Patients are allowed up on the third day after operation under cocaine and are allowed to go home on the sixth day. When I went to Cardiff in 1888 I looked upon removal of a goitre as an anxious, difficult, and dangerous operation, although my present colleagues and friend, Dr. O. T. Vachell, had done pioneer work in this direction at the Cardiff Infirmary and had been subjected to adverse criticism for his daring by those who advocated subcutaneous injection treatment. It was not until I had the privilege and opportunity of seeing Professor Kocher repeatedly perform such operations that my views and opinion were completely changed.

SEVEN CASES OF GENERAL PERITONITIS
TREATED BY OPERATION, WITH
FIVE RECOVERIES.By B. MATTHEW BONE, M.B., C.M. EDIN.,
F.R.C.S. EDIN.

IN view of the extreme importance of arriving at some definite conclusions as to the best means to be adopted in the treatment of general peritonitis, I venture to publish my notes of seven cases within I have had the opportunity of treating since May, 1934. I notice that they to a certain extent support the views put forward by Mr. A. W. Mayo Robson in his *Practical Obstetrics* and published in THE LANCET of Dec. 23rd, 1935, that by the limited operative treatment a fair percentage of recoveries may be looked for. In my own series of cases the case rate is 23.5 per cent. and the recovery-rate 71.5 per cent.

CASE 1. Appendicitis, general peritonitis; operation; recovery.—At 10 P.M. on May 6th, 1934, I was called in consultation with Dr. A. S. Buchanan of Redcar to see a married woman, aged 52 years, who had been ill for four days. She looked extremely ill and was slightly propped. The abdomen was much distended and a dull could be felt across the lower part. Her illness commenced with pain in the right iliac fossa, which became general all over the abdomen. During the last 24 hours her condition had become steadily worse and the abdominal pain was easier. No induration or tumour could be felt. She also suffered great pain when vomiting. I opened the abdomen along the outer border of the right rectus muscle. Foul pus was at once evacuated from the peritoneal cavity. I found the appendix partially gangrenous and perforated, adhering to the bladder. There had been an abscess in the retro-peritoneal pouch which had burst and discharged its contents into the peritoneum. The pus, which was most offensive, was removed by means of aseptic gauze swabs, the various peritoneal pouches being dealt with one after the other. A large drainage-tube with gauze wick was inserted into the pelvis and gauze drains into the abdominal cavity and right loin. The patient made a good slow recovery and was out in a cain chair at the end of a month. The appendix contained a coagulation and had perforated.

CASE 2. Appendicitis, general peritonitis; operation; recovery.—The patient, a man, aged 43 years, was seen by me upon the third day of his illness. He looked extremely ill, with an anxious expression and sunken eyes. His abdomen was very distended. There was general tenderness to touch all over the abdomen; his pulse was 130 per minute. The patient's chance of recovery appeared to be small. I opened the abdomen and found the appendix balled in foul-smelling pus, there were no limiting adhesions or plastic lymph. The appendix was gangrenous at its distal end and perforated, but no coagulation was found at the operation. The foul pus was removed by aseptic gauze swabs, a large drainage-tube was inserted with a gauze wick, and a gauze drain was put in the right loin. Recovery was slow but steady. The wound healed, all but a very narrow fistula, which after six weeks two small appendiceal concretions were discharged, when it healed within a week.

CASE 3. Appendicitis, general peritonitis; operation; recovery.—The patient, a man, aged 58 years, was seen by me upon the third day of his illness. He complained of rigidity and pain all over the abdomen. The pain could be described, mainly in the right iliac region and had been very severe for some hours; he had not morphine given to relieve the pain. He had vomited green bile twice that day. He looked very ill, with an anxious expression and a pinched countenance. No induration or tumour could be felt. I opened the abdomen and at once found a quantity of foul-smelling pus in the peritoneal cavity. There were no limiting adhesions or plastic lymph. The appendix was free and unswollen, with a black-looking perforation near the base, there only just being room to amputate it close to the caecum. Having removed the appendix the pus was cleared away with dry aseptic gauze swabs and a large drain was inserted with a gauze wick and a gauze drain in the right loin. The patient made an excellent recovery and was up at the end of a month. Concretions of the pus-thrombus in the lumen.

CASE 4. Appendicitis, general peritonitis; operation; recovery.—

CASE 4.—I was called to see the patient, a man, aged 43 years, in consultation with Dr. Douglas Bone of Carlisle, upon the fourth day of his illness. He was extremely ill, with a pulse of 140 and an abdomen tensely distended. Vomiting had occurred at intervals and he had a dry, hard tongue. Operation was advised as holding out the only chance of recovery. His illness commenced with abdominal pain which was at no time particularly apparent in any one place. There was a hard thrill over the lower part of the abdomen. I performed abdominal section and at once evacuated a pint or so of offensive pus from the peritoneal cavity. There were no adhesions or plastic lymph. The appendix was found and was gangrenous, with a coagulation protruding through the tip. Fully another pint of pus was removed from the pelvis and the peritoneum was cleaned as far as possible with gauze swabs. A large drainage-tube was inserted into the pelvis with gauze wicks and other gauze drains were placed in the abdomen and loin. The patient was now so collapsed that I feared he would die upon the table. He was therefore replaced in bed without an enterotomy which I had intended to relieve the intestinal distension and paresis. He never rallied in spite of all that was tried and died on the following morning.

CASE 5. Ruptured pyosalpinx; general peritonitis; operation; recovery.—The patient, a married woman, aged 35 years, who had had two children and several miscarriages, complained of abdominal pain which commenced over the right iliac region. Vomiting occurred every few hours. The patient looked very ill. The abdomen was very distended and a hard thrill could be felt across the lower part. I opened the abdomen and found free pus which was not offensive in odour. The right tube contained a quantity of pus and had ruptured. There were no adhesions or lymph and the tube was not adherent. The tube and ovary on the right side were removed; the left tube was healthy, as was also the appendix. The pus was removed with dry gauze swabs and a large appagapic drainage-tube inserted with a gauze wick. Several other gauze drains were introduced in various directions. The patient made a rapid recovery and left her bed at the end of three weeks.

CASE 6. Appendicitis, general peritonitis; optic haematomas around the right kidney; operation; death.—The patient, aged three days, was seen in consultation with Dr. W. Scott on the third day. The following history was given. The infant had screamed the day previous to my visit in what the mother called an "unnatural" way. It had also been "screaming" just previously to my visit. On examination the abdomen was moderately distended and rigid, with the legs drawn up and spasm of rectum. Peristalsis a tumour could be felt high up on the right side. I opened the abdomen and at once evacuated a quantity of turbid fluid. There were no adhesions or plastic lymph. I discovered the inflamed appendix adherent by one-half of its length to the caecum. The appendix was removed and a "cigarette" gauze drain was inserted, with a gauze drain in the right loin. The infant died the following day.

CASE 7. Appendicitis, premature labour, general peritonitis; recovery.—The patient, a primipara, aged 24 years, was taken suddenly ill with pain confined to the right side of the abdomen; she was then seven months pregnant. Hot fomentations were applied without relief and the next day labour set in and at midnight she was delivered of a child. When I saw her on the third day of her illness, having been confined the night previous, she was desperate ill. Her pulse was 150 and her temperature was 105.5° F. She was delirious, with a loss of extreme anxiety or even fear upon her countenance. There was distension of the abdomen and the uterus could not be felt. She was also sweating freely from the forehead. A hard thrill was most to be felt. I opened the abdomen in the middle line and found free foul-smelling pus in the peritoneal cavity. This was removed by means of dry aseptic swabs and then the appendix was found free and perforated near its base and extensively distended. The appendix was removed and the pus was carefully taken up on gauze swabs. A large appagapic drainage tube was inserted with gauze wick and gauze drains were placed in various directions amongst the coils of intestine. The patient made a slow but good recovery.

The chief points in the treatment and after treatment of the series of cases were these: (1) removal of the cause; (2) removal of the pus as far as possible by means of dry aseptic gauze swabs; (3) free drainage with tube and gauze wicks and plain streams of gauze; (4) care to be as gentle as

of restoring it to its former position in such a skilful manner "that not even a scar was left, but only a thin white thread-line encircled her beautiful neck as evidence of the miracle of the seventh century."

During the last two years I have adopted Dr. Albert Kocher's¹ suggestion of placing the patient in the position shown in the illustration (Fig. 1). This position makes a

REGISTRATION COMMITTEE OF THE WORSHIPFUL COMPANY OF PLUMBERS.—Dr. Reginald Dudfield, medical officer of health of Paddington, has been appointed to represent the Incorporated Society of Medical Officers of Health on the Registration Committee for the National Registration of Plumbers.

¹ Dr. Albert Kocher is Professor Kocher's son.

be heard at a distance of one inch only; at the present time it can be heard at five inches. This is a most useful ear; it is her only available one, and fortunately it is now safer than if the ear had never been diseased, for the mastoid antrum (the danger zone) has been removed; also all discharge has ceased and the perforation in Shrapnell's membrane has healed.

CASE 2. "Attic" disease.—The patient was first seen in July, 1906, with a history of discharge from the left ear lasting two months, following one week of pain. There were giddiness and slight headache. The watch was not heard on contact. Air could not be blown through the perforation by Valsalva's method, though the Eustachian tube was free. There was a polypus about half an inch long in the meatus and after its removal it was possible to see that the perforation was in Shrapnell's membrane. Spirit drops were ordered to be instilled several times a day.

On a subsequent visit a small recurrent polypus was removed and it was found that the otorrhea had increased. In these circumstances operation was recommended and the conservative one was performed on Oct. 25th. Cheesy pus and a few granulations were found in the antrum and pus in some mastoid cells communicating with the antrum. On opening the cartilaginous meatus as usual towards the conclusion of the operation the membrane was fully exposed and then were removed some granulations from within the attic; a probe was passed through the perforation and the attic into the aditus, air was then blown through. On looking into the posterior attic granulations could be seen.

The experiences gained by the operation on Case 1 did not encourage the attempt to force the tympanic obstruction. Four days after the operation this patient also could blow air through the perforation, which indicated that the tympanic barrier had disappeared. Before the operation the watch could not be heard when in contact with the ear; at the present time it is heard 11 inches away. His recovery was uneventful; the perforation healed and all discharge ceased.

CASE 3. "Attic" disease.—The patient was admitted to the hospital on Nov. 2nd, 1906, with a history of four months' discharge from the left ear, tinnitus, and pain over the mastoid. The watch was heard only when in contact with the ear. There was a greyish granulation of about the size of a pea apparently growing through the roof of the meatus but in reality through the upper part of Shrapnell's membrane. Air could not be blown through the perforation from the nose, although the Eustachian tube was clear.

The conservative operation was performed on Nov. 16th. The aditus contained thick pus, and on probing from behind through the attic to the perforation after removal of granulations some white material was thrust out through the perforation, which on examination proved to be a flake of glistening epithelium of about the size of the section of a lead pencil. The probing was continued and two or three similar flakes were removed in the same way. Then air was blown through and all desquamated epithelium was cleared away. This patient progressed satisfactorily and in a few days could blow air through the perforation by Valsalva's method, but developing an infectious disease she was removed. This was a most interesting case and her departure was disappointing.

CASE 4. Facial paralysis.—The patient was admitted to the hospital on Nov. 12th, 1906, with a history of nine days' facial paralysis and a discharge from the right ear of 27 years' duration. The paralysis was as marked as in any case in my experience, and the patient's appearance distressed her greatly. The large exposure of the eye demanded the use of pad and bandage to keep the lid down and thus protect the cornea.

The conservative operation was performed on Nov. 15th. The mastoid antrum contained granulations and pus. Air and lotion were passed through the tympanum from the aditus and forced out through the perforation. There were no apparent granulations, even after 27 years' suppuration. This patient went home on Dec. 2nd. The facial paralysis had disappeared, the discharge had ceased, and she could shut the eye of the affected side as strongly as the other. Before the operation she heard the watch at two and a half inches; she now hears it at six inches, and with her best ear she can hear it at ten inches.

CASE 5. An old ossiculotomy case.—The patient was admitted to the hospital on Nov. 5th for operation on the left ear, after two years' treatment as an out-patient. There had been otorrhea for 14 years but never any pain. There was a cicatricial band on the inner wall of the tympanum and below it a carious patch. The whole tympanum was wet with fetid pus. She could hear the watch at a distance of two inches in that ear and in the other at 14 inches. An operation had been performed at another hospital, probably ossiculotomy and curetting.

The conservative operation was performed on this patient also. The antrum was large and full of granulations wet with pus. The aditus

contained granulations. The removal of the pyogenic membrane lining the antrum and aditus and therefore the cessation of supply of pus to the tympanum permitted the latter, although it was in no way treated, to make a satisfactory and rapid recovery. Of course, not a perfect recovery, as the drum membrane and ossicles had been taken away by the operation of ossiculotomy 12 years before. The caries rapidly healed and all discharge ceased. The patient was in the hospital three weeks and on leaving could hear the watch at four and a half inches, twice as far as before the operation.

The foregoing notes on these five cases provide matters demanding serious consideration. To take the so-called "attic" cases first, it may be observed that all had disease of the mastoid antrum although the aural discharge was not of long duration nor were there any mastoid symptoms. All had such swelling of the tympanic mucous membrane as to prevent the passage of air and discharge from the antrum or perforation to the Eustachian tube or *vice versa*. In all that firm obstruction spontaneously disappeared within a week of the operation—that is, as soon as the irritation of the tympanum, arising from the presence of pus from the antrum, had been eliminated by the operative proceedings—and none had "attic" disease, so understood, unless the accidental ingrowth of epithelium in one of them could be so called. This ingrowth of epithelium in time might have spread and its products have accumulated anywhere within the tympanum, but more especially in the posterior "attic" portion, for the rest of the tympano-attic cavity was obstructed by the barrier of swollen mucous membrane referred to above or by granulations, therefore the accumulation taking place in the direction of least resistance would naturally occur in the "attic."

How these facts concerning "attic" disease contrast with what has so long been taught about it! And this information is the result of close observation of the living and could not possibly have been demonstrated post mortem; each of these persons suffered from disease of the mastoid antrum affecting secondarily both the attic and tympanum, and in one patient the conditions leading to cholesteatoma were present. The locality in which the perforation occurred appeared to depend on the amount of swelling in the tympanum, which by protecting the rest of the membrane insured that perforation should take place in Shrapnell's membrane; it was the only part exposed.

In the two cases which remained under observation the discharge ceased, the perforations healed, and the hearing greatly improved; also the vertigo and pain disappeared, implying a termination of the disease, due, not to treatment of the tympanum but to the elimination of the mastoid antrum and its putrid discharge which had been irritating the tympanum. Although the giddiness was due to tympanic conditions, treatment of the tympanum, except destructive operation, would not have removed it. The main disease was not in the tympanum or attic at all but in the mastoid antrum—it was mastoid disease, and thus it should be named. The patient in Case 1, in whom air was blown through an artificial opening, showed that the obstruction to the passage of air through the tympanum was unyielding and that therefore the apposition of the swollen mucous membrane of the inner tympanic wall to the drum membrane must have been an accurate moulding in order to prevent the passage of air under such a great pressure as was used in the attempt to force a passage.

Cases 1 and 2 both complained of giddiness, which can be accounted for by the external pressure exercised upon the incus, by means of the swelling of the mucous membrane of the tympanic inner wall, which, pushing out the lower part of that bone until further progress was resisted by its anchorage to the stapes, pulled upon the stirrup and by dragging on the ligaments tended to diminish the pressure in the labyrinth. This was enough not only to account for the vertigo but might even account for the pain. Tympanic obstruction of a less degree is a very common condition in chronic suppuration and swelling of this kind combined with the amount of blood-supply form the chief factors in deciding where a perforation of the drum membrane shall take place.

The patient in Case 2, with giddiness, pain, and nerve deafness, might have been suspected of having labyrinthine implication, but the symptoms were probably the result of alteration of labyrinthine tension due to tympanic swelling as explained above. The labyrinth is far more rarely involved in this

Forceps for removing granulations, &c., from the tympanum or attic. The full-sized ends show the three patterns which are in use—the straight forceps above, those bent to the right in the centre, and those bent to the left below.

possible in all manipulations; and (5) counteracting shock by all means possible. Strychnine and brandy were administered before and after the operation. Gastric lavage was employed before and after operation in cases where vomiting was present. Large quantities of saline solution were administered after operation per rectum every four hours, sometimes with brandy added. Nothing was allowed by the mouth for the first 24 hours after operation except a teaspoonful of albumin water every half hour, and not this if any sickness was present. One-sixth of a grain of calomel was administered at once after operation and one-sixth of a grain every fourth hour until one and a half grains had been given. Turpentine enemata were used with the rectal tube passed high up to relieve flatus and distension. And, lastly, but by no means to my mind the least important, the patients were placed in the Fowler position by means of a bolster beneath the knees and a back-rest, the bolster being retained in position by two bandages tied to the bed head on either side.

I think there are other points of great importance in influencing the result of operative treatment. Firstly, rapidity combined with gentleness in manipulation and thoroughness of operation. Secondly, the administration of the anæsthetic. If the patient has a terror of the operation or is excessively nervous the initial administration of ethyl chloride, I believe, is extremely useful, as it renders the patient anæsthetic in about 30 seconds and allows the exhibition of ether or chloroform to follow it at once without difficulty. It also shortens the duration of the operation in that often the surgeon, if he sees that he has everything prepared, may make the incision under the ethyl-chloride anæsthesia and may have time to open the peritoneum before its effects have completely passed off. This allows of the operation being carried through with the minimum of ether or chloroform, it being only needful to push it a little towards the end if sutures are to be introduced or another incision made for drainage. I consider the limitation of the anæsthetic to the minimum necessary as of extreme importance in these cases. It is also of great importance to keep the patient warm during operation, and to this end a hot-water tank on the operating table is very valuable, and also I employ a jacket for the patient's body with sleeves out of which there is no opening, a small slit being provided at the wrist to enable the pulse to be felt. I also have leggings with socks all in one which pull up to the top of the thigh. These are made of thick woollen blanket and, I find, keep the patient warm. As little of the surface of the body should be exposed as possible.

Lancaster.

THE TREATMENT OF CHRONIC SUPPURATION OF THE MIDDLE EAR WITHOUT THE REMOVAL OF THE DRUM MEMBRANE AND OSSICLES.

By CHARLES J. HEATH, F.R.C.S. ENG.,

SURGEON TO THE THROAT HOSPITAL, GOLDEN-SQUARE, LONDON.

THERE should no longer be any doubt of the fact that chronic suppuration of the middle ear, if promptly treated, is usually curable, with restoration of hearing and with healing of the perforated drum membrane. It appears also that practically every man or woman who suffers from chronic suppuration of the middle ear has disease of the mastoid antrum, and although occasionally the discharge may cease with or without treatment on account of a favourable anatomical formation of the antrum and aditus, this fact does not invalidate the contention that while there is chronic suppuration there is disease of the mastoid antrum. These statements are founded on the experiences of over 500 mastoid operations performed during the various stages of this disease, and in all those patients not in one instance was the mastoid antrum in a condition of health.

Since the publication of a previous paper on this subject many surgeons have seen my patients and operations at the Throat Hospital and have adopted the procedure advocated in a large number of cases with great success. The operation affords no great difficulties, nor is it accompanied by much danger, for after years of gradual diminution mortality

has now disappeared among those patients submitted to operation before dangerous symptoms have developed.

The patients referred to in my previous paper were admitted to the Golden-square Hospital because they were serious cases of chronic suppuration in the middle ear; they all had perforation in some part of the tense portion of the drum membrane and the aural disease varied in duration from three months to 18 years. Some had polypus in the meatus, others granulations in the tympanum, one had a discharging sinus behind the ear, all had deafness and fetid discharge, and some in whom the disease had become acute were in great danger from extensive exposure of the dura mater of the middle brain and the lateral sinus in the acute mastoid abscess. Yet such severe cases as these were shown to be capable of complete recovery, with cessation of discharge, healing of the perforation, and perfect restoration of hearing. These ten patients were exhibited at a meeting of the British Laryngological and Otological Association¹ and the result of the discussion was greatly in favour of the new operation. One or two who took part in the discussion expressed their doubts as to the new method being adequate to deal with "attic" disease (so-called). In my reply, the belief was expressed that by operating in time it would be possible to prevent the "attic" from being involved and that recently, when operating fairly early on three patients with "attic" disease, serious disease of the mastoid antrum had been found in all of them, and probably the "attic" disease would be recovered from when the diseased cavity of the antrum was eradicated. These expectations regarding the possible cure of "attic" disease were so far fulfilled that at the next meeting of the association, a month later, two of those three "attic" patients were exhibited completely recovered from the disease, with the discharge ceased, with the perforation in the membrane healed, and with much hearing restored. The third patient had been removed from the hospital before recovery because she developed an infectious disease which demanded her removal to another institution.

Not only are the ordinary forms of chronic suppuration of the middle ear amenable to the new treatment, but it is equally effective in the attic form also. In October and November last some of the rarer and more complicated forms of suppuration came under observation and operation, such as "attic" disease (so-called) with perforation of Shrapnell's membrane and chronic suppuration associated with facial paralysis. Particulars of these cases are recorded below and, in addition, details of a most interesting and instructive case in which the operation of ossiculectomy had been performed 12 years previously for the purpose of attempting to cure chronic suppuration in the ear.

The following five cases were exhibited at the meeting of the British Laryngological and Otological Association on Dec. 7th, 1906:—

CASE 1. *Attic disease (so-called).*—The patient, aged 24 years, was admitted to the Throat Hospital on Sept. 21st, 1906, complaining of pain in the right ear, also of a feeling of giddiness even when lying down. There had been discharge for six months from this ear. In down. There was a perforation of Shrapnell's membrane. She could hear the watch at a distance of one inch. The Eustachian tube was free but not communicating with the perforation, there being some obstruction to the passage of air through the tympanum, and in order to attempt to save the hearing of this, her only useful ear, operation was decided upon and was performed on Oct. 11th. The conservative operation was adopted, as described in THE LANCET of August 11th, 1906, p. 353.

There was pus in the antrum and that cavity was draining through a perforation in Shrapnell's membrane. The probe was passed completely through the posterior part of the "attic" from the perforation in the membrane to the aditus; air was then blown through. Next, having obstructed the perforation with a wet woollen mop, an attempt was made to force air forwards through the tympanic cavity, from the aditus to the anterior part of the tympanum near the Eustachian tube, and to distend the tympanum, but without success, it escaped through the perforation in spite of the occlusion of that opening by through the wet woollen mop firmly held. Next, by incision, an artificial opening was made in the anterior inferior quadrant of the drum membrane, and a cannula, which had been prepared for the purpose, was passed through the opening, and an attempt was made to force air backwards through the tympanum from the neighbourhood of the Eustachian tube to the aditus, but this, too, was unsuccessful; of the obstruction in the tympanic cavity was unyielding. No further attempts at forcing a passage were made.

In this patient a small part of the bridge above the perforation was removed, this has been done in three other cases in order to examine the attic. On the sixth day after the operation the patient could blow air through the perforation by Valsalva's method, indicating that the obstinate tympanic obstruction had been spontaneously removed; also it was observed that the artificial opening which had been made also in the membrane was healed. Before the operation the watch could

Cases which are devoid of apparent granulations are slower in recovering after operation, and by being less protected are more liable to the penetration of disease into the tympanic walls leading to caries, a far more serious condition, as in the facial paralysis case. Many other pathological matters noticed in this investigation are in entire conflict with the teaching hitherto accepted, and if the old pathology were right the gratifying results of this new treatment at the hands of many surgeons would be impossible; it is however founded, and fortunately so, upon a new aspect of pathology of this disease.

Some surgeons have lately informed me that they are operating by this new method on patients whom they have had under observation for years, but dared not operate by the radical operation as it might destroy the hearing of the only useful ear (such conditions prevailed in Case 1). This operation might be called the conservative operation, because it is designed to save what is essential to perfect hearing; but the name is a small matter as the evolution of the operation was a certainty once the true pathology was known. What, however, was most important was the recognition of the fact that the pathology hitherto taught was not to be relied on, and the duty of acquiring a more accurate knowledge of the nature of this serious disease has demanded years of the closest clinical study, for as long as the old pathology dominated the surgery of this disease no advance was possible; as long as the tympanum was considered the root of the disease so long would the disastrous results of the radical operation and ossiculectomy be perpetuated.

Many questions as to the scope of this operation have reached me from surgeons in this country and abroad; it is not a simple opening up of the antrum and a clearing of that cavity and the aditus followed by drainage, as in Schwartz's operation, which caused so many disappointments and led to the institution of the radical operation, which, on the other hand, went much too far. In the new operation not only the posterior superior part of the meatus is removed, as in some other operations, but the antrum and aditus are practically eliminated, as well as all disease associated with those cavities. The whole posterior wall of the bony meatus and even its arched floor must also be removed, and this latter proceeding is followed in no other operation, but it must be done if that full access to the tympanum which is necessary both during and after the operation is to be assured. This is essential not only for the safe and thorough removal of granulations, polypi, &c., at the operation, but especially for the dressings during the after-treatment, for without the removal of the floor it is impossible to see the whole of the membrane; moreover, a pocket would be left between the arched floor and the membrane where discharge might accumulate.

Already over 100 of these operations have been performed in the country for chronic suppuration, and it is also being practised in America. Between 20 and 30 have taken place at my hands; two surgeons of my acquaintance have, together, and in a shorter period, performed a similar number, and one of them, a resident in a northern city, is so satisfied with his results that some months ago he had adopted this method in 12 out of 15 mastoid operations and has exhibited some of his patients at the local branch of the British Medical Association.

It is not claimed that under all diseased conditions of the tympanum this elimination of the antrum and aditus is to be expected to restore the ear to health, for the drum membrane may be extensively destroyed or completely gone; the ossicles, too, may have necrosed and disappeared, as sometimes happens in scarlet fever and other acute diseases, but this does not occur in chronic disease. For such cases the radical operation will still be required, yet they form a small proportion and will rapidly diminish, as the treatment of this disease is more promptly undertaken on the lines recommended herein. The surgeon's aim should be the restoration of a perfect ear. The aim, however, of the radical operation and the hope of ossiculectomy is to get the discharge stopped with a certainty of a defective ear.

It is as much the duty of the aural surgeon to operate in time to save the hearing as it is that of the ophthalmic surgeon to operate in time in chronic glaucoma to save the sight.

RECENT DEVELOPMENTS IN THE THERAPEUTICAL APPLICATIONS OF ARSENIC.

By J. SNOWMAN, M.D. BRUX., M.R.O.P. LOND.

MODERN advances in the progress of pharmaceutical science are not confined to the invention of highly complex and synthetic organic preparations. Research must necessarily be prosecuted along this line because it has already produced remedies of permanent value to our daily pharmacopœia. But though investigation may mainly proceed in this direction, it will be occasionally worth while to devote some attention to our old-fashioned and time-honoured drugs. This attention will often be rewarded by the discovery that neither all their therapeutical nor their pharmaceutical applications have been exhausted. Some of the recent studies in arsenic exemplify this contention in a striking degree and a review of the present position of this drug in the treatment of disease may therefore be both opportune and profitable.

Arsenic must always command the interest of the clinician because its toxicology is so reminiscent of pathological processes. It is often instructive to study the action of drugs from the point of view of their influence either on structure or on function. The pharmacology of opium, strychnine, and digitalis, for instance, mainly concerns function; while potassium iodide, phosphorus, and arsenic may be regarded as drugs the value of which chiefly depends upon the circumstance that they produce structural alterations in the tissues. If the alteration tends to restore a pathological condition of a tissue to its normal state the drug will be credited with a specific curative action. Our control of pharmacological action is, however, too imperfect to enable us to arrange our employment of remedies in such a manner as to guarantee that structures of morbid anatomy will revert into those of health. The group of drugs formerly known as alteratives possess the property of modifying the nutritive processes in the body. It is obvious that this effect involves definite chemical changes in cell constitution, and advanced changes of this character inevitably modify structure. The great value of alteratives in therapeutics is that they often change pathological processes brought about by disease into physiological processes. Their failure frequently arises from the circumstance that they introduce into the body their own toxic pathological processes. This is exceedingly well exemplified by arsenic, which is able to produce a mimicry of several diseases, much to the discomfiture of diagnosticians. In the nervous system we may have peripheral neuritis with rapid muscular atrophy, or definite myelitis. The intestinal canal may present appearances closely resembling cholera, with granular changes proceeding to fatty degeneration in the epithelial lining, the interstitial tissue and Peyer's patches being invaded by large round granulated cells. The liver may be affected in such a manner as to suggest a diagnosis of acute yellow atrophy. The skin may be the site of lesions the number of which is almost legion. Every anatomical manifestation known to dermatology from a slight erythema to a bulla is represented. The most characteristic appearances, however, are pigmentation, herpes zoster, and hyperkeratosis of the palms and soles. Hutchinson maintains that these thickenings may develop into true epitheliomatous growths.

The sphere of action of arsenic is obviously very extensive when it is allowed to act on the general healthy organism. Its danger lies in its tendency to cause fatty infiltration and degeneration, and its therapeutical applications are accordingly very much hampered, though practical medicine still indicates a considerable field for its employment. Happily, recent investigations are indicating how the drug may be used so as to obtain its therapeutical effects with a considerably diminished risk of incurring its toxic consequences. It is probable that the organism itself provides a defence against arsenical poisoning, in a manner similar to the production of an antitoxin in the case of certain bacterial poisons. It is found that subcutaneous injection of arsenious acid into rabbits in large but not fatal doses is followed by a prolonged leucocytæmia. This increase in polymorphonuclear leucocytes, it should be added, is preceded by a temporary decrease in their number. The point, however, is that after the increase has occurred each leucocyte contains arsenic. If a fatal dose is injected no

country than abroad, if statistics are to be considered reliable.

The hearing of these two patients considerably improved after their recovery, but it does not compare favourably with the cases already recorded in *THE LANCET* and with many other cases treated since, and the reason is not far to seek, for the tension in, and therefore the sensibility of, the labyrinth was altered by the long-continued stretching of the stapedial ligaments; also, the ossicular chain of bones, and their intervening joints, and the vibrating tympanic membrane itself had all suffered by the long-continued stretching and pressure to which they were subjected by the outward swelling of the mucous membrane of the tympanic inner wall. Even better results regarding the hearing might therefore have been expected had they been operated upon even earlier, before the tympanic swelling had damaged the labyrinth and the ossicular chain and attachments. (The hearing of these two patients is slowly and steadily improving.) Again, the whole week of pain suffered by Case 2 before the perforation occurred suggests the gradual accumulation of the drainage from the antrum which appears to secrete but little, and contrasts therefore with the abundant discharge observed when the tympanum is much affected.

Case 3 exhibited conditions indicating the commencement of cholesteatoma, and in this patient it appears to have been due to the implanting of the squamous epithelium of the outer surface of the drum membrane upon the granulation which happened to be in close contact with it. The squamous epithelium was probably first implanted upon the protruding granulation, which being large and coming like a button through a buttonhole might have been tightly nipped round its neck by the edge of the perforation and possibly excoriated there, and once the epithelium from the outer edge of the drum membrane became implanted it might grow and travel over the surface of the granulation, along its stem, and thus inwards through the perforation, until it reached the general mucous membrane of the tympanic attic of which the granulation was a part, and there the effete epithelium becoming thrown off would naturally accumulate and lead to cholesteatoma; also the squamous epithelium might continue to extend over the mucous surface of the cavity. The grey-white appearance of the granulation itself might indeed have indicated a covering of squamous epithelium, but it was unfortunately not microscopically examined.

Observations such as these may assist in settling the disputed origin of cholesteatoma and should it ultimately be generally concluded that this is the way in which it usually originates valuable hints are obtained as to what surgical or other treatment is desirable in order to prevent such a calamity.

From experiences of these cases there appears much difficulty in recognising any disease as peculiar to the attic as well as any peculiar to the tympanum. That such a division seems arbitrary, as the tympanum, and its upper part the attic, together form one tiny cavity; it is an attempt at a distinction without a difference, for granulations or caries may be present in either locality or in both, as in the cases recorded above, the disease merely being modified by the anatomy of the part. Further, that whether the pathological changes are apparently more in the tympanum or more in the attic, the conditions are secondary to disease of the mastoid antrum. Again, the discharge from the antrum which causes the attic or tympanic disease has to pass through the attic in every case to reach the perforation wherever it may happen to be, whether in the tympanic or attic portion of the drum membrane, and to call this disease by the name "tympanic" or "attic" because of the situation of the perforation, high or low, seems devoid of all reason. Moreover, practically all these cases are curable by the same operation if dealt with at the proper time. The following conclusion was therefore ultimately reached—namely, that however diverse the conditions in the ears of different persons may appear to be in the late stages of suppuration, they all appear to fall into one category in the early stages—that is, disease in the mastoid antrum—for it can now be demonstrated that the same principle governs them all, and therefore the same treatment may be expected to be effective in all if carried out at the proper time.

The above cases emphasise the importance of an early operation when the disease settles down into a condition of chronic suppuration. The majority of cases of acute

suppuration, however, recover completely; they do not become chronic.

The use of the Politzer bag is especially indicated after operations upon these attic cases, for the ossicles and joints have been pressed upon by swelling, and their loosening and shaking up and the breaking of their adhesions are as necessary here as in any other part of the body after somewhat similar conditions of strain and subsequently an enforced rest.

In Case 4 (with a history of suppuration for 27 years and of facial paralysis for nine days at the date of admission) there can be no reasonable doubt that the cause of the paralysis was the onset of caries, as anything short of that would probably not have affected the bony aqueduct and the nerve after such a long period of disease. This case demonstrated that such a serious disease as caries of the tympanum can be recovered from even without the removal of the drum membrane, as is done in the radical operation, if the cavity is freed from the irritating effects of putrid discharge from the mastoid antrum by a less destructive method, and as there was no apparent protective swelling of the tympanic mucous membrane in this patient there was greater liability to caries of the walls of the cavity as the result of the irritation from the discharge from the antrum.

In Case 5 an operation was performed 12 years ago on the patient through the meatus, probably ossiculectomy, with the hope of curing chronic suppurative catarrh. This case illustrates the fact that ossiculectomy was not to be relied upon to stop otorrhoea, but was in fact futile, for it did not reach the dangerous disease in the mastoid antrum, and thus make the life of the patient safe, in spite of the sacrifice of all possibility of restoring the hearing, and even if ossiculectomy would cure the mastoid disease the fact of its destroying the hearing should prevent its adoption. This case shows also that even without the presence of the drum membrane caries can be produced on the inner wall of the tympanum and perpetuated there by discharges draining down from the mastoid antrum, and that it can be recovered from when that discharge is arrested. There can be no doubt as to the presence of caries in this case, for bare bone could be felt by the probe and its situation proved by observation prior to the operation, but more fully demonstrated when the meatus had been enlarged, as is the rule in this method of operation.

To take the facial paralysis and ossiculectomy cases together. In each there was caries in the tympanum; in the first it appeared after 27 years of suppuration and in the second it was observed after disease of 14 years' duration. In both it disappeared when the discharge was arrested by operation on the mastoid antrum, the fountain-head of the suppuration which caused the caries, and not by operating on the seat of the caries in the tympanum. These facts, it will be observed, are in direct opposition to the teaching hitherto in vogue.

Caries is rare; so are the results of that disease such as facial paralysis and labyrinthine suppuration, yet suppuration is extremely common, and if caries was the cause of it, it should always be present. It does not need the presence of caries to cause perpetuation of suppuration, while the mastoid antrum is the factory of fetid pus, for which the tympanum has to act as the drain and is thereby constantly irritated and perpetually discharging. Caries is not, as has been hitherto taught, the cause of the persistence of suppuration, but according to the investigations noted above it is the effect of that persistence.

Further, and a most important point common to these five cases, serious diseases of the mastoid antrum were found in all of them, even in those of but short duration—a matter that could only be demonstrated by an early operation such as was done in some of them; and this fact again emphasises the contention that practically all cases which do not recover after acute catarrh and relapse into a chronic suppuration have disease in the mastoid antrum. As remarked before, for practical purposes there is no exception to this rule, and the fact that some cases do recover on account of exceptionally favourable conditions of the aditus and antrum (not to be relied upon nor to be diagnosed) does not invalidate the contention that while there is chronic suppuration going on there is disease in the mastoid antrum. The results of these and other operations appear to show that those ears are the healthiest and most vigorous in which the tympanic swelling and granulations are most abundant.

alopecia, which showed no improvement, dermatitis herpetiformis, xanthoma, psoriasis, and lichen. The average duration for the cure of 20 cases of psoriasis was 29 days and for ten cases of lichen 25 days.⁶ Both these series were treated with external applications in addition. But cases of lichen treated exclusively with atoxyl all gave excellent results. The worst case required 42 injections. It was found that after a few injections the itching of the skin subsided, the papules became flatter and paler, the scalliness diminished, and finally nothing remained but a little faint pigmentation. In regard to psoriasis, the reports indicate that atoxyl must be supplemented by local remedies. After about six injections the infiltration becomes less and the scales decrease, but apparently a thorough cure cannot be relied upon. Guszman of Budapest,⁷ however, has achieved such remarkable success by the energetic use of atoxyl in psoriasis without any other treatment that he looks upon it as a specific. He points out the great advantage of this method of treatment when the use of baths and inunctions would be difficult. He agrees, however, that the employment of local measures distinctly expedites the cure. Atoxyl tends to increase the circulation in the cutaneous capillaries, and assists, therefore, in the absorption of pathological pigmentations such as chloasma. A case of xanthoma treated in Lassar's clinic⁸ exhibited flattening of the plaques after the fourth injection. The colour became less intense, and after 22 injections a perfect recovery ensued. Again, a young girl whose face was covered with yellow warts received nine injections of atoxyl on alternate days, and this sufficed to cause their absolute disappearance. A series of 18 injections resulted in the absorption of numerous subcutaneous endotheliomatous tumours in the case of a man aged 68 years.⁹ Naturally atoxyl has been applied to other general morbid conditions wherein arsenic finds a field for employment. The improvement in nutrition which follows the use of the cacodylates in pulmonary tuberculosis obtains also in the case of atoxyl. Cases of anæmia and chlorosis which appeared to resist iron treatment¹⁰ did well and finally became quite cured under a course of atoxyl. It should be noted that in these cases the first indications of improvement concerned the nervous symptoms of the disease, such as the headache, giddiness, and palpitation. Mendel has used the drug in neurasthenia, hysteria, facial paralysis, sciatica, and spasmodic asthma, and he regards it as a perfect substitute for arsenic. It is eminently applicable in chorea and is one of the most successful remedies for Graves's diseases. In three cases of this condition the symptoms practically subsided in from six to eight weeks. Atoxyl also finds an excellent application in the neurotic disturbances associated with the climacteric.

The very latest investigations into the action of this drug are concerned with the therapeutics of trypanosomiasis. It has been demonstrated by Laveran and Mesnil that arsenic kills the trypanosomes circulating in the blood. It can, however, only be relied upon to cure the disease in an animal which otherwise possesses great resisting power, because this lethal action of arsenic on the parasites ceases with the excretion of the drug or on its combination with the fixed tissue elements. It follows, therefore, that the trypanosomes which have not been destroyed continue to exist and multiply and circulate in the blood stream, as the examination of a film will prove. Atoxyl possesses the same action as arsenic, but can be pushed to a much greater extent than the latter. The following scheme indicates the specific action of atoxyl on the parasites when administered to an animal suffering from trypanosomiasis.¹¹

First 4 hours ...	No change.
4 to 5 hours ...	Trypanosomes swell; movements diminish.
7 hours ...	Movements slow; protoplasm in irregularly disposed granules, with ground-glass appearance and vacuolated. Shape of parasites deformed, but their number not greatly decreased.
3 hours ...	Sudden diminution in number, from 40 in a field to 3.
15 hours ...	Absolute disappearance; centrifugalised blood shows no parasites. A great increase of leucocytes.

There is a disease in horses, known as dourine, confined to

Algiers and North America, due to the trypanosoma equiperdum, as discovered by Rouget in 1894. The symptoms consist of inflammation of the genitals, oedema of the abdomen, eruptions, and inflamed glands. Wasting, anæmia, and paralysis follow. It has been clearly proved by experiments that the introduction of atoxyl into the blood absolutely prevents the development of the disease in susceptible animals as a result of inoculation.¹²

The reports of Robert Koch and others on the treatment of sleeping sickness by atoxyl are distinctly encouraging. In a recent report he records a trial of this drug in 986 cases of the mild and severe varieties. In the former class he included those patients who complained of impaired movement of the legs with pains therein and had swollen glands which contained the trypanosome. In the latter variety were included those who exhibited tremors, unsteady gait, going on to complete helplessness. After atoxyl injections the weakness gave way to increased power and very many of the patients were again able to walk about. Some desperate cases even lost their drowsiness, consciousness returned, and they improved so much as to walk about without assistance. So far authorities do not allow themselves to put their trust in atoxyl to effect a cure, but its therapeutical activity in that direction is undoubted.

There seems to be every prospect that this drug will acquire a permanent and very valuable position in the pharmacopœia. It should therefore be pointed out that idiosyncrasy to this drug may exist. A case is recorded of an adult who suffered from amaurosis, oedema of skin, and hyperkeratosis after the continued injection of atoxyl,¹³ but it is not clear whether the aniline may not have been concerned with the production of this untoward effect. Those who have had most experience of the use of atoxyl state that the only unpleasant results they have noted were dragging pains in the extremities, which, however, were quite evanescent.

Brondesbury, N.W.

THE BALNEOLOGICAL TREATMENT OF URINARY DISEASES.

BY DR. OSCAR KRAUS.

THE last few years have seen a notable change in the ideas dominating the field of balneology as well as in the domain of medicine in general. This is due to the fact that our views of physiological processes have been changing, that we are no longer prone to consider the human body as a chemical laboratory, pure and simple, that, on the contrary, we are now taking proper account of other non-chemical biological processes. As a result our views on the mechanism of the healing process and the indications for bath treatment and particularly on the "specificity" of the curative agents have become correspondingly clearer and more rational.

Purely external conditions assign to balneotherapy a field of action peculiarly its own. The patients whom a physician sees in the city are, as a rule, either bedridden or well enough to attend to their business. The physician at a mineral spring, however, has to do with a third class of patients—viz., with such as are not bedridden but nevertheless do not need to attend to professional duties and can and will therefore devote the whole work of the day to the treatment of the maladies. It is at once apparent from this that results may be attained on general hygienic principles—entirely apart from any therapeutic power of the various waters themselves—results, however, which are fundamentally a part of the particular province of balneotherapy in the broader sense.

There are, generally speaking, few affections, especially chronic ones, which will not be benefited by a rational dietetic and climatic general treatment of longer or shorter duration. But of particular value, at any rate for certain diseases, must be the profound influence upon certain phases of the metabolic process, such as the digestion and urinary functions, which may be brought about by so powerful a medication as, e.g., the Carlsbad mineral water.

In giving the following report out of my 18 years' experience in treating urinary cases in Carlsbad I do so primarily because the matter is of paramount professional interest to

leucocytosis takes place, neither do the white cells contain any arsenic. The inference, therefore, is that the increase in leucocytes and the presence of arsenic therein are associated with the establishment of immunity or tolerance. The importance of this observation lies in the fact that arsenic has been found of great value in various blood diseases, notably leucocythæmia, pernicious anæmia, and chlorosis. As a result of experimental work it is quite certain that the nutrition of growing bone is improved by the administration of small doses of arsenic. According to Stockman and Charteris¹ the action on bone marrow is also very definite. The leucoblastic cells are formed in increased number and a resulting leucocytosis ensues. There is, however, no indication of any increased production of red corpuscles. On the other hand, excessive doses lead to a hyaline degeneration of the bone marrow cells, with a decrease in both red and white corpuscles. It must be noted, too, that although arsenic is the most approved drug for the treatment of pernicious anæmia it does itself cause increased blood destruction when given in poisonous doses. The pigmentation which is a feature of the toxæmia of arsenic is probably due to the deposit in the skin of hæmoglobin derivatives.² The profound influence which arsenic is able to exert on the organism has, as already mentioned, secured it a position in the group somewhat vaguely called alteratives. Its chemical position is, however, more defined as a member of the nitrogen group, which includes also such powerful elements as phosphorus and antimony. Nitrogen is the cardinal constituent of the protoid molecule, but apparently other members of the nitrogen group are able to take its place in the molecule. Obviously the substitution of arsenic for nitrogen must alter the whole chemical physiology of the body. The change manifests itself as a fatty degeneration of protoid tissue, in which the liver, kidneys, heart, and muscle share. There is a larger excretion of nitrogen, mainly in the form of ammonia. The formation of glycogen in the tissues is diminished, but an increase of lactic acid takes place in the blood and therefore its alkalinity is lessened.

The art of employing arsenic in medicine consists of gaining control of its pharmacological action and making it subservient to therapeutic aims. As is well known, the Styrian peasants have long succeeded in applying this drug to the purpose of increasing the vigour of the male population and enhancing the physical charms of the female. Perhaps one of the best-established facts in the therapeutics of arsenic is that it modifies the nutrition of the skin. The adipose tissue is certainly increased, and the Styrian ladies take advantage of this circumstance to improve their complexion. There must, however, be some specific action on the epithelium; fatty degeneration of the lower layers has been suggested. There is also some modification in the orderly process of the shedding of the cutaneous epithelium. The fact, however, remains that its influence in skin disease is a matter of considerable therapeutical value.

The other departments of disease which are favourably affected by arsenic are represented by such diverse conditions as chorea, malaria, and the anæmias. The rationale of its action is indefinite. In chorea, for instance, the abatement of symptoms may be due to improvement in general nutrition or to specific action, either on nerve centres or definite toxins. In malaria the plasmodium is probably destroyed by arsenic, on the analogy of certain observations made in trypanosomiasis, which are referred to later. The clinical value of arsenic in the anæmias, including leucæmia, pernicious anæmia, and also lymphadenoma, is undoubted; but it must be confessed that in view of conflicting statements regarding its hæmatinic action the *modus operandi* remains obscure. It may, however, be laid down as a golden rule in the treatment of chlorosis that arsenic should be combined with iron when the red cell count falls below 3,000,000 per cubic millimetre. In a severe degree of chlorosis the iron may be relied on to increase the hæmoglobin, while the action of the arsenic will assist in the production of new red corpuscles.³ The pharmacopœial preparation of iron arsenate must be given in such minute doses that the amount of iron contained therein is necessarily a negligible quantity. An exceedingly useful and effective combination of these two drugs is to be found in arseno-ferrate, where the iron is presented as an organic protoid compound and is of undoubted therapeutic activity in chlorosis and cases of

secondary anæmia.⁴ The arsenic exists in this preparation in the form of arseno-albumin. In regard to other combinations of arsenic reference should be made to bromide of arsenic, which may be given in minim doses of a 2 per cent. solution. This has been found serviceable in diabetic cases with nerve complications. Arsenate of strychnine is a preparation which has been found useful in severe cardiac asthenia of an influenza type for patients who will not tolerate the usual mixture of iron, quinine, and strychnine.

The impetus to the chemical modification of arsenic was mainly given by the desire to obtain a preparation whose therapeutical value should not be prejudiced by its toxicity. Accordingly, in 1897 Danlos introduced cacodylic acid which is chemically di-methyl arsenic acid. Its sodium salt—sodium cacodylate—is occasionally disguised under the names of arsinyl or arrhenal. The arsenic exists in this compound in very close combination and its liberation in the body is a very slow and gradual process. This consideration is regarded as the explanation of its low toxicity. The cacodylates certainly gained wide popularity as safe and efficient substitutes for arsenic. Their reputation in chronic pulmonary tuberculosis was remarkable and they sustained the credit of arsenic for improving nutrition when metabolism was deranged in wasting diseases. They were applied to every therapeutical purpose to which arsenic is put, but with conflicting results. Fraser, for instance, used the cacodylates in many diseases which are benefited by arsenic, but he could not satisfy himself of their value. Hypodermic injection was the favourite method of administration and $\frac{1}{4}$ th of a grain is an average dose. As much as $\frac{1}{4}$ to 1 grain may be given by the month. Hefter⁵ states that not more than $\frac{1}{10}$ th of the cacodylate of soda is decomposed in the body. At any rate, the odour of cacodyl As (OH)₂ is evident in the exhalations of the patient.

It should be said that some of the older dermatologists of the nineteenth century had already resorted to the hypodermic administration of arsenic in order to prevent the irritative action of the drug on the intestinal mucous membrane and in order to secure its specific virtues with more reliability. When lichen ruber planus was treated largely by pills containing arsenic (Asiatic pills) something like the number of 1000 constituted an average course; but subsequently it was found that 30 hypodermic injections sufficed to attain the same end. In 1897 Herxheimer advanced upon this and injected up to $\frac{1}{10}$ th of a gramme of arsenious acid into the veins for psoriasis. He cured his cases in an average of 48 days. The Levico arsenical water has been used for hypodermics with good results. The records of the first attempts at the hypodermic administration of arsenic supply a goodly number of unpleasant accidents, and these to a great extent were responsible for the introduction of the cacodylates.

At the present moment, however, interest in the potential developments of arsenic is concentrated in the combination known as atoxyl. Chemically this substance is meta-arsenic anilid ($\text{O}_2\text{H}_3\text{AsO}_2$). It was first used in 1900 in Lassar's skin clinic, after its properties had been determined by experiments on rabbits. It contains metallic arsenic in the proportion of 37.69 per cent., or, in other words, half the amount of arsenic present in arsenious acid. It possesses one-fortieth part of the toxicity of arsenic or one-twentieth of that of arsenious acid. It is an odourless white powder with slightly saline taste and its solubility in warm water is 1 in 5. Its solution is stable and does not give the characteristic tests for arsenic. Atoxyl has now had a somewhat prolonged trial and the clinical results justify the conclusions that (1) it affords the means of increasing the amount of arsenic given without the risk of poisoning; (2) it possesses in full measure all the therapeutical properties of arsenic; and (3) that its value is proportionate to the increase of arsenic which its administration permits. The favourite method of the exhibition of this drug is by hypodermic injection. Originally $\frac{1}{10}$ th of a gramme was given, but experience now shows that the dose should start with $\frac{1}{10}$ th of a gramme and go up to $\frac{1}{4}$ th of a gramme. When it has been determined to give a course of arsenic over any prolonged period the most convenient plan is to inject $\frac{1}{4}$ th of a gramme of atoxyl twice a week. Intravenous and also intramuscular injections are employed, but subcutaneous injections are unirritating and quite efficient. The earliest cases treated by atoxyl were dermatological. They included

It is usually accompanied by disturbances of circulation the deeper pelvic organs. Moreover, the increased bowel activity and the flushing out of the urinary apparatus act as a depletive. Reference cannot too often be made to the very intimate reciprocal relations between intestine and urinary tract; it is a result of their contiguity, of their common blood- and lymph-supply, and in part common nerve-supply and musculature. We will neglect the controversial question as to the penetration of the bladder wall the colon bacillus; he it only said that we never see strikingly the defervescent action of a laxative in an acute attack of fever as after operations on the urinary passages or in affections of this apparatus.

Turning again to nephritis, or rather to the different sections grouped under the name Bright's disease, we have to admit that we are as little able to cure them completely by balneotherapy as we are by any other measures. I hope none will expect such results of us. On the other hand, balneotherapeutic treatment is particularly well fitted to combat certain symptoms with success. In those cases where the quantity of urine is low we see a rapid rise. We all return to this point again. As to the behaviour of the albumin and formed elements in the urine I am not able to make a detailed report before completing certain experiments now in hand, which I shall reserve for a future communication. I may say, however, that my experiences at this point have been encouraging.

We should lay particular weight on the behaviour of that group of symptoms which Bouchard has called symptoms of *toxic uræmia*. These are the remoter or general symptoms which we have mentioned earlier as the result of toxic influences. Such are gastric and intestinal disturbances, anorexia, profuse diarrhoea or chronic constipation, hemiparesis, hiccup, as well as certain forms of paroxysmal frequency of micturition, or "pollakiuria," a term introduced in medicine by Dieulafoy, phenomena which from their whole nature are to be regarded as toxic. These are favourably affected by every stimulation of renal or intestinal secretory activity. This fact will be especially emphasised if we remember that Biedl and Kraus were able to demonstrate the elimination of various bacteria through the kidney, such as the bacillus coli, staphylococcus, &c., and that they could facilitate this elimination by stimulating the flow of urine. (This is also naturally of importance with regard to certain infective varieties of nephritis. Indeed, we observed in such acute cases rapidly successful results with no other medication than large quantities of mineral water to induce diuresis.) These patients improve notably at Carlsbad, recover appetite and regularity of the bowels, gain in weight, and lose the distressing headaches; their complexion improves—that characteristic toxic complexion—and good humour returns. The physician forgets too often that patients who cannot be cured need and will demand treatment. They are the ones who are most thankful for relief from distressing symptoms, and so much the more thankful if, like most nephritics, they are unaware of the seriousness of their condition and regard the remoter symptoms as the most important or as the whole disease itself.

And so I have more or less defined the goal which balneological treatment has in view for nephritis. My experience has been that compensated heart lesion, even oedema if of a slight degree, are not contra-indications for Carlsbad treatment provided that it is carried out carefully and in the right way. On the other hand, patients with ascites—and, strangely enough, they keep coming to Carlsbad as a last resort—are quite miserable there, as might be expected, and their medical men have to get them home again for their pains. I remember two such cases where I was compelled to tap the abdomen soon after arrival.

Nephritis with serious circulatory derangements (hypertrophy and dilatation of the ventricles) with considerable oedema had better not be sent to Carlsbad, not even *solatis causâ*, because the heart-pump is too sorely taxed by the increased amount of fluid taken, as well as by the walks, especially the climbing, which patients at a resort will indulge in, in spite of the doctor's advice. I should like to add another consideration. Nephritics catch cold easily, therefore they should be sent to a place which is subject to so sudden temperature changes as Carlsbad only at the most favourable season of the year. I have had some rather unpleasant experiences in this connexion.

As to renal tumours, there is nothing to be said except that we occasionally see them in Carlsbad after hæmorrhages,

when they have been taken for stone in the kidney. They are, of course, sent at once to the surgeon as soon as the diagnosis is made.

Without wishing to go further into the question of pyelonephritis, pyonephrosis, and other such forms of infection, we must speak of *pyelitis*. This is sometimes due to calculus formation, the *pyelitis calculosa*, or may be of the ascending variety, the *cysto-pyelitis*. The treatment of the first depends on that of the *nephrolithiasis*. The treatment of the second must not only consist in flushing out the infected urinary apparatus by the "drinking cure" and helping in the elimination of the toxins, but must be directed as well against the various local conditions in bladder, ureters, and prostate. Every case of *pyelitis* is sooner or later sent to Carlsbad and one may say, without being too sanguine, that a beneficial effect of the water cure is evident not only in those forms of *pyelitis* where the removal of the causal factor is possible (*pyelitis calculosa*, certain forms of *cysto-pyelitis*) but even in the incurable forms as well. Whether the infection is purely of colon type, or whether it is mixed with proteus, staphylococcus or streptococcus, the increased diuresis and the elimination of the toxins through intestine and kidney seem to play a definite part in bringing about recovery. For many years alkaline waters have been used "to dissolve the concretion and to mitigate the inflammation." We shall presently discuss whether it is possible or not to dissolve the concretion, but the healing effect of the alkalies upon the inflamed pelvic mucous membrane is, at any rate, most apparent in Carlsbad.

We come now to the discussion of *nephrolithiasis*. Among the laity the opinion still prevails that Carlsbad water is able actually to dissolve kidney- or bladder-stones. Strange to say, this opinion has also crept into professional literature without meeting criticism. It is recorded in a Carlsbad publication by Dr. Springsfeld of the year 1756, "*Commentatio de prerogativa Thermarum Carolinensium in dissolvendo calculo renicæ præ aqua calisviæ*," that a kidney-stone of almost two and a half ounces (i.e., about 87 grammes) in weight was dissolved in six days "entirely to a pap, like fine, soft chalk," in sprudelwater.² Springsfeld's other data are all as inexact as that mentioned and give no indication as to the chemical constitution of the stone thus softened. However, we once took the trouble to make a similar test with a urate stone of about the size of a hazel-nut, obtained through the kindness of the late Professor von Dittel. It was a calculus removed, with several others, by a *scietio alta*. We put it into a vessel and for 24 hours let Carlsbad water flow in and out, the whole being maintained at body temperature on a water-bath. The concretion remained unchanged, a loss of weight of only a few milligrammes being appreciable, such as was to be explained by the mechanical breaking and floating off of superficial particles. This experiment proves that uratic stones are not even dissolved *in vitro*; any attempt at a solution of them by the injection of Carlsbad water into the bladder, as has been proposed by some, must therefore *a priori* be condemned as hopeless.

That a solution of calculi in the bladder cannot be brought about by *drinking* the water need only be pointed out to the laity, among whom this superstition still prevails. On the other hand, experience teaches us that concretions both of the kidney or its pelvis and of the bladder may be driven out by the drinking-cure here. The increased diuresis resulting from the latter is beyond question and to this chiefly is to be ascribed the discharge of the stones.

The question, when can Carlsbad treatment promise a success and when ought surgery to assert its rights will be considered in the sequel.

(To be continued.)

WEST LONDON POST-GRADUATE COLLEGE.—The inaugural lecture of the summer session will be delivered by Major Leonard Rogers, I.M.S., on Monday, May 13th, at 5 p.m. The title of the lecture is "The Clinical Diagnosis of Fevers in the Tropics," illustrated by lantern slides. Anyone interested who would like to attend will have a card of admission sent on application to Mr. L. A. Bidwell at the West London Hospital.

me and because I believe that in this chapter of therapeutics there remain many questions yet to be answered, many errors yet to be set right. The first of these questions is fundamental: whether, in reality, for patients with a diseased urinary apparatus there is a need for a balneological course of treatment or not? The answer is found in the practice of every day: such patients are, as a matter of fact, sent to the baths, therefore, there must be a felt need of that kind of treatment. The question only remains, whether we may expect such treatment to benefit our patients and, if so, to what degree? I do not wish to be misunderstood; the mere fact the patients visit the baths is in itself certainly no proof of the necessity of bath treatment; the triteness of the phrase "fashionable watering-place" is sufficient testimony to that. But when genuine invalids, such as patients with urinary diseases really are, are sent to a watering-place the conscientious physician must not only feel the need but also be convinced of the expediency of this treatment. If asked what are the indications in such cases for balneological treatment we may give a fairly general answer. Those patients should as a rule be sent whose progress at home is not as satisfactory as might be desired, whether the aim be a complete recovery through influence on the metabolism in general or by local treatment of the urinary organs in particular, or whether in the case of incurable processes one expects an ameliorating effect both on general condition and on particular disease symptoms through the specific healing properties of the mineral-water in question and the general benefit of the *régime*—or whether finally the processes to be combated are in reality those of a generally disordered metabolism and only happen to make themselves evident through the urinary system, as in the case of renal calculus, diabetes mellitus, diabetes insipidus, &c.

It is hardly necessary here to go into the specific properties of the Carlsbad thermal waters; others have discussed them for centuries before us. The properties of Carlsbad waters are beyond controversy which justify their use more especially in diseases of the urinary apparatus. These mineral waters have a favourable influence on the functions of all mucous membranes, especially of those of the bladder and bowel, and they stimulate intestinal and renal activity to a marked degree. We will bear these points in mind, they furnish a starting-point for our inquiries.

It is far from my present purpose to go into the pathology of urinary diseases, I wish only to speak of a certain few factors which have impressed their importance upon me in my practice. As is well known, the diseases of the urinary apparatus may be broadly divided into two groups, the one where local and the other where general symptoms play the chief rôle. The majority of the local affections have an infective origin, while a toxic character prevails in the other group. As I am to confine myself to purely clinical observations I may be allowed to make use of this purely clinical classification.

Of first importance is the question: How do the diseases of the kidney fare at Carlsbad, what is our experience with them there? We will speak, to begin with, of acute and subacute diffuse nephritis. Of late years we have been seeing them more frequently at Carlsbad, and, I must add, have been glad to see them. I at least have had a favourable experience with them. Without further remarks I will give the following case as an example.

An English lawyer, aged 42 years, consulted me in the summer of 1902. Within the year he had been having hæmorrhage from the kidneys, which had lasted with remissions until he came to Carlsbad. Rather in consideration of pain in the left kidney region, of the fact that his father had once undergone an operation for stone, of the sedentary life of the patient, and of the scanty uric acid excretion said to be present, than of any typical course of the disease, a probable diagnosis of nephrolithiasis had been made. To be sure, the possibility had been left open by his conscientious adviser of a hæmorrhage "from another cause." I have mentioned here the nationality of the patient with a reason. It is well-known that England was the starting-point of the movement which defends most emphatically a diagnostico-therapeutic incision of the renal capsule. At the annual meeting of the British Medical Association at Cheltenham surgeons expressed themselves in favour of such an incision in just such cases as the one here cited. If a stone is found it is removed; if not, the after-effects of the operation, due, as is said, to a

"relief of kidney tension," are beneficial, and the pain and the hæmorrhage are said always to disappear. This effect would be comparable to that of an operation for glaucoma. However, the more recent views as to the harmlessness and the favourable after-effects of the operation are by no means so unmixed, and Barth's word of warning with regard to diagnostic nephrotomy at the Berlin Chirurgical Congress in 1900 seems to have found response both in England and on the continent. The two well-known surgeons whom this patient had consulted had spoken of operation as a last resort but were quite agreed in sending him to Carlsbad to begin with. When I saw him first he had a continual dull pain in the left kidney region. The left kidney was tender to pressure. There had been no attacks of colicky pain. In the urine was a layer of blood sediment of a finger's breadth but no clot. The treatment ordered consisted of drinking the waters and heat applications (mud packs) to the kidney region. In a few days the sediment (i.e., the hæmorrhage) had become so scanty that one could recognise, besides the erythrocytes, characteristic blood casts and kidney epithelium. The quantity of albumin was greater than that to be explained by the blood present. Further, in the course of treatment the pain and hæmorrhage disappeared completely. There was never any trace of uric acid and never any trace of pus in the urine. Other points which were in favour of the diagnosis of nephritis need not be here enumerated (as a matter of fact the case was: probably one of the post-scarlatinal form), but I wish merely to throw some light on those aspects of the case which were of weight as regards treatment. How are we to explain the cessation of the pain and the hæmorrhage? It is generally accepted that the pain in diffuse nephritis is due to an over-stretching of the capsule from enlargement of the kidney. The diuretic action of Carlsbad water has been so freely discussed by Sandberg, Ewald, Jaworsky, London, &c., that I may properly assume that it is generally familiar. Now Leube recommends the administration of large quantities of alkaline carbonated waters in the early stage of nephritis; and when we remember that Anfrecht regards an occlusion of the tubules of Henle as the cause of the anuria, the mode of action of a diuretic mineral water becomes obvious. As Fürbringer first suggested for infective nephritis the micro-organisms themselves do not seem to be the cause of the kidney injury; this injury seems rather to be attributable to a product of the metabolism of the pathogenic bacteria, to a poison which is excreted through the kidneys. It may be assumed that a diuretic mineral water favours the excretion of the toxins, dilutes them, and so diminishes their harmful action, explaining in this way the favourable results which follow the use of such waters.

The increased diuresis certainly favoured the cessation of the renal hæmorrhage in this case, as in many similar ones that I have seen. The first necessity for hæmostasis is always the elimination, the "flushing-out" of coagula—a process without which the contractile elements in the pelvis or the calices cannot act properly. For example, in checking a hæmorrhage from the bladder the bladder must first be washed clean from clots, these being removed by whatever expedient is necessary, even to aspiration with an evacuator. It is plain that the diuretics works in a similar way upon the kidney.

We learned in school that in case of hæmorrhage, whether of the kidney or elsewhere, the bleeding organ is to be kept at rest and the vaso-constrictors are to be stimulated by cold applications. It will be remembered that I had ordered hot applications, thus departing seriously from traditions. Moreover, the patient in question had by no means kept his bed; he had taken no violent exercise to be sure, but he had taken walks and thus failed to "keep the kidney quiet." Nevertheless, the hitherto refractory hæmorrhage ceased in this as in very many similar cases immediately the treatment was begun. It is not to be assumed that this was a mere coincidence but that the warm compresses first soothed pain, then dilated the urinary passages, opening an unimpeded outlet for the increased diuresis, and that in this manner, as explained above, the elimination of the coagula took place.

I can also record similar results in prostatic cases. Of course, the mechanism is here rather different. We know that the bleeding in prostatic hypertrophy usually comes on at the height of one of the recurrent attacks of congestion

1 I wish to emphasise that the causal connexion between the commencement of treatment and the cessation of the hæmorrhage had continued in spite of the usual measures the hæmorrhage had continued unabated for weeks before the Carlsbad treatment was begun.

allow of the poison being worked off in small non-lethal doses. It seems to me that if the circulation be brought to a standstill at the seat of injection it might be possible, if this be done early enough, to prevent any venom at all entering. The venom would be imprisoned, as it were, and could be dealt with by permanganate of potash and incisions. I suggest, therefore, that in cases seen early enough the part be frozen with ethyl chloride spray during the making of the incisions and the rubbing in of permanganate of potash. Where the subcutaneous cellular tissue is loose the part containing the imprisoned poison might be shut off from the general circulation by ligature should needles and thread be handy. All the operations would be painless. A tube of ethyl chloride would not be a large addition to a snake-bite outfit.

Kayana, Cape Colony.

A CASE OF POISONING BY COAL-GAS.

By JOHN REID, M.D. ABERD.

THE patient in the present case was a female child, born on Feb. 20th. When I saw her and her mother on that day I called attention to a slight escape of gas from a bracket in the centre of the room. This bracket was not in use but was tied to the ceiling. On the 21st neither the mother nor the child seemed to suffer from the escaping gas. The room was large and a good fire was burning. On March 8th the child could not suck and had the usual signs of capillary bronchitis. She was in the kitchen, which was somewhat draughty. On the 9th she was removed to the room in which she was born but which had been out of use for a day or two. The change took place after my midday visit, at which I found that marked improvement had occurred in her lung symptoms and that she was able to suck. On the 10th I found very few rales on auscultation, but her lips were chocolate coloured and she was rolling her tongue in the mouth as if gasping for breath. She offered no resistance to examining her throat or to depressing the tongue; on the contrary, there was marked apathy. The eyelids were puffed and a thick mucus exuded from the edges of the swollen lids. The conjunctiva was red on the 8th and was so on this date, but the cornea had the dull lustre found in interstitial keratitis. The pupil was small; the general aspect of the face was ashy; the mouth was dry; and on the tongue there was thick mucus, but no saliva. The mucus seemed to be pushed out of the mouth by the rolling movements of the tongue and to reaccumulate. There was cyanosis of the soft palate, which was of the same colour as the lips. The abdomen was tympanitic and when it was pressed the child showed some signs of uneasiness. She was constipated but the bowels had been well opened on the 9th. She was placed suitably for fresh air and was fed by milk given with a spoon. On the 11th the skin of the body had a dusky or ashy hue. The bowels had been moved by a piece of soap in the rectum and the tympanic appearance had subsided. The eyelids were now open and there was no mucus on the lids—probably a boric acid lotion had removed it—but the cornea and conjunctiva were injected and the dull look suggesting keratitis was still present. The lips were chocolate coloured and the soft palate was cyanosed. There was a slight improvement in the movements of the tongue, but there still was thick mucus in the mouth. The child took milk readily from a spoon. On the 12th there was a bright roseolar rash over the whole body, including the head. A few sudamina were present, but there were large rosy red patches over great parts of the surface. A magnifying glass showed that the condition was a dermatitis or bleeding under the skin rather than a proper eruption. The colour was bright red. The tongue was now bright red, intolerant of touch, and covered with aphthae. It was difficult to feed the child but she took milk which was given to her. The chocolate colour of the lips and the cyanosis of the soft palate were now less marked. The condition of the cornea was unchanged. The lungs gave no signs of disease, but only of dryness of the tubes. The motions were black (melæna).

The child's state on March 13th was about the same as on the 12th but the soft palate and lips were now red and showed no chocolate colour. On the 14th her state in the morning was much the same as on the 13th, but towards the

evening the rash and aphthae had pretty well disappeared. She took milk which was given her. The injection of the cornea had passed off but the dull lustreless appearance remained. There were frequent fits of difficult breathing with cyanosis during the day. On the 15th the child looked almost moribund in the morning, but improved with the inhalation described subsequently. There were frequent fits with chocolate colouring of the lips and palate. From the 12th to the 14th there was occasional yawning. It should be mentioned that these fits were not like those met with in fevers and lung affections. There was a semi-comatose state with a chocolate colouring of the lips, which passed off after a time, especially on rousing. In the evening the cornea became more natural and the child's general appearance improved. After the rash had disappeared, in the morning a few bright red patches made their appearance on the fingers; these alone were seen. Her general appearance was more natural, her bowels acted, and the motions were now natural. She was spoon-fed with mother's milk. On the 16th in the morning she had a convulsive seizure, a general convulsion of an epileptic nature, with foaming at the mouth but with little cyanosis. She had been fed during the night and the milk had been returned curdled. Jelly and trypsinised milk were now substituted and retained. At 6 P.M. the child looked natural; she had had no fits but her heart's action was weak. She died from syncope at 7.50 P.M. Marked hypostatic lividity was observed 16 hours after death and a roseolar raised eruption, of a dull character, was at the same time present over the body but not on the head; it was, however, much less copious than during life.

The mother's milk, which ceased on the 10th, was brought back on the 12th by pilocarpine, and on the 16th she had lost all the cyanotic signs from her lips. Evidently the first symptoms of carbon monoxide poisoning were paralysis of the salivary, lacteal, and lacrymal glands, with headache in the case of the mother, and stimulation of mucous glands, or glands of organic life. The fit which the child had on the morning of the 16th was, I think, owing to enfeebled circulation and was not of the carbon monoxide type. The milk had been returned from the stomach curdled.

The treatment up to March 14th consisted of fresh air, appropriate diet, and calomel to move the bowels, and boric acid lotion to bathe the eyes and tongue, with medicines likely to improve secretion. On the 14th, inhalation of chlorine was commenced, the process employed being to mix 10 grains of potassium chlorate with 30 minims of dilute hydrochloric acid in a teacup which was placed near the child's nose until evident signs of irritation occurred. This was frequently repeated during the day. Two minims of this were also added to a two-ounce mixture, of which one-sixteenth part was taken every three hours. It will be observed that the remedy was used late in the case of a very young child, and that no steps were taken to minimise the effects of the release of considerable quantities of carbon dioxide by the chlorine, which formed carbon oxychloride. Probably a more leisurely action employed at an earlier stage would be a safer remedy unless oxygen were available for inhalation, as it was not in this case. I should state that I first used dilute phosphoric acid and potassium chlorate in the mixture, but I think that little or no chlorine resulted from this. The mother recovered rapidly under the treatment. It is rather strange that a dusky or earthy colour at first covered the body. This, I think, was hæmorrhage or pigment of a punctate character. The bright red colour (rash) did not appear till the third day.

Although the antidote was used in the case of a very young subject, debilitated by broncho-pneumonia and tonsillitis (influenza), I feel confident that early and judicious treatment by the chlorine antidote would have led to recovery. As it was death resulted from syncope. It is noteworthy that the mother and child managed to live during the puerperium in the room with a leakage of gas which was repaired on March 11th. The gas became ignited and continued to burn when a lighted match was placed at the point of leakage. The accumulation of gas through the disuse of the room during two days was sufficient to produce very evident signs of poisoning. The child slept in a perambulator, with a hood, both in the kitchen and bedroom. The nursing was good. An inquest was held and the jury returned a verdict in accordance with my evidence.

Walbrook, E.C.

TWO CASES OF SNAKE-BITE, WITH A SUGGESTION FOR TREATMENT.

By WALTER H. HAW, B.A., M.R.C.S. ENG., L.S.A.

ON Nov. 23rd, 1906, I was sent for to see a native girl, aged about 16 years, alleged to have been bitten on the outer surface of the foot at 5 P.M. on the previous evening by a small snake a few inches long. It was described as having a comparatively large head and is well known to the residents here as a "dik-kop adder" (thick-head adder) or "spring-adder," on account of its jumping propensities, I suppose, when irritated. Apparently the snake is the "horned viper," or hornman, but none of the several who had seen it mentioned the presence of horns above the eyes. The animal had been killed, cut open, and the raw surface applied to the wounds after these had been scarified and a ligature applied above the ankle. The girl, after having been bitten, ran at once back to the house and was naturally terribly scared. As far as I could make out no symptoms occurred until about 8 P.M., when vomiting and dimness of vision came on, as well as drowsiness, which increased and necessitated her being kept awake all night. I saw her first at about 12 o'clock mid-day on the following day. She was lying on a pallet in a dark hut, surrounded as usual in serious illness by all her friends and relatives. She was on her right side and the eyes were closed. I am sorry that I am not able to give a more detailed account of the condition of the nervous system, but, of course, my chief attention was directed to what proved to be hopeless attempts to save life. What I have to say was rapidly noted in the course of the treatment.

On the outer side of the left foot, below and in front of the outer malleolus, were the marks of scarifications which had bled. As these had been made through the punctures made by the fangs the latter were not visible, but the farmer who had taken the chief part in the "first aid" informed me that there had been three punctures, suggesting that she had been bitten twice. These were in a single row and had bled. The whole foot was swollen, but I saw no discolouration of skin, ecchymosis, or necrosis of tissue in the region of the bite. A ligature was tightly bound round the leg above the ankle. The leg above this ligature was also swollen and there was a second ligature round the leg below the knee. Above this ligature nothing abnormal was noted externally. The patient lay apparently asleep but could be roused on being shouted at by name and would answer shortly. On being asked if she had pain anywhere, the answer was, "No; only in the leg." If asked to turn over the attempt would be made but without success. The arms and legs could be moved and apparently tactile sensation was not gone from the face, for spasmodic and abortive attempts were made to brush away the flies which had settled on the face and lips. Being asked to put out the tongue the mouth was opened but the tongue did not protrude. There was no objection to the prick of the hypodermic needle in the injured foot, some pain was evidently felt on inserting the needle below the right scapula, and decided struggling occurred on inserting it below the right breast. The breathing was shallow, with marked expiratory phase (not counted), and the pulse was full and strong (also not counted). The respirations were, I should judge, from 20 to 24, and the pulse would be about 90. There was no marked salivation. The eyes were closed and were not opened in response to a request to do so. The upper eyelids were swollen and presented a pinkish-blue discolouration. The colour of the face was not much changed beyond some pallor, which deepened just before death. There had been no hemorrhages. On lifting the eyelids the eyeballs were fixed and staring with dilated pupils, which did not react to the little light in the chamber. No attempt was made to test the ocular muscles or the optic nerve, but the impression which the position and look of the eyeballs gave me was that both paralysis and blindness were present. On one occasion the father of the girl lifted her into a sitting position, when it was noticed that the muscles supporting the head were paralysed, the latter falling about like a flail and having to be supported. I thought, also, that the breathing became more embarrassed while the patient was in the sitting position. When a teaspoonful of a mixture containing strychnine was placed in the mouth it was discovered that the power of

swallowing was lost, so that the face had to be turned downwards to allow the fluid to run out, for it threatened the larynx. These abortive attempts to swallow appeared to throw the breathing into greater difficulties and shortly afterwards I noticed that the breathing was going to stop, so I tried artificial respiration for some time but in spite of this it steadily and rapidly grew shallower until it ceased altogether. At the moment that the breathing proper finally ceased (what followed were only the final gasps of death) I felt the pulse to be then beating strongly but it slowly grew weaker in spite of the attempts to keep it going by artificial respiration and ceased from five to ten minutes (exact time not taken) after the last respiratory effort, which actually drew air into the lungs. Just before the breathing ceased flatus was passed by the anus. The symptoms observed conformed to those described as resulting from the injection into animals of colubrine venom.

A more fortunate issue attended the treatment of another case of snake-bite which occurred in my practice two years previously and of which I give a *résumé*.

On Dec. 14th, 1904, two natives walked into my surgery, one of them stating that his mate had been bitten on the foot a few hours previously by a night adder. The wounds had been cut into, so that no punctures were visible. Being workers on the railway being built here they were some distance from the village when the accident occurred, but they did not lose much time in coming for help. The man bitten complained of nothing but some dimness of vision and he did not appear to be much concerned about the matter. There was no swelling or discolouration round the alleged seat of wound beyond the general swelling of the foot due to a ligature above the ankle and he seemed, with the exception of the slight dimness of sight, to be in full possession of his faculties, both mental and physical, so much so that I was rather sceptical about his having been bitten, although I am aware that natives are no "slouches" in the matter of snake-bite and seldom or never accuse themselves falsely of having been bitten. The snake had been killed but of having been brought in to me. I injected a solution of permanganate of potash round the alleged seat of the bite, left the ligature, which had been tightly applied above the ankle, in position, and gave him a mixture containing liquor strychninae, ten minims for a dose. They would not stay in the village, but went home to their huts on the railway line. Two days after, on Dec. 16th, 1904, the same two natives walked into my surgery, and on this occasion the one was leading the other, who had his eyes closed, and held his head high in efforts to see under the upper lids. On being asked to open his eyes he made an attempt to do so, but ended by lifting the lids with his fingers. He was therefore suffering from ptosis of both upper lids. On examining the eyeballs themselves I found both pupils widely dilated and the globes fixed and staring, with no action either to light or to accommodation. There was no blindness, for he could count fingers at the distance of a few paces, and no apparent loss of sensation. On testing the musculature of the eyeballs I found that on looking to the right the right eye moved well towards the outer canthus, while the left remained looking straight forward. Similarly on looking towards the left the left eye moved well towards the outer canthus, while the right remained looking straight forward. No movement either upwards or downwards could be obtained. On testing all the other cranial nerves in order, as well as the spinal nerves, nothing abnormal was elicited. Apparently all sensation was normal. There was therefore a complete paralysis of both third nerves on the third day after the bite of a night adder. I repeated his strychnine mixture and did not see him again, but was informed that he and recovered later. He was not taking belladonna and I got no history that he had taken any native herb which might cause such paralysis. His intellect was quite calm and clear.

With regard to the treatment of snake-bite, I am unaware whether the suggestion I am about to offer has been previously made, but as it seems to me to be in accordance with the dictates of common sense I give it for what it may be worth. I have had no opportunity of trying it, but I shall do so on the first occasion. The great difficulty in the treatment of snake-bite is to keep the venom out of the circulation. If this could be effectually done until such time as the venom is destroyed it may be possible to save more lives than is now being done. The usual method of preventing the venom entering the circulation is by means of the ligature and one is advised to slacken it occasionally to

The operation was prolonged. The patient's radial pulse became very irregular but was fairly forcible. The circulation in the foot of the affected limb seemed to be fairly good though the pulse in the dorsalis pedis artery could not be felt. After the operation the limb was massaged in an upward direction for a short time every hour so as to aid the venous circulation. On Oct. 20th the wound was dressed and the drainage-tube removed. The limb was a good colour and quite warm. Slight fulness was noted on the inner side of the ankle and there was some numbness present on the inner side of the leg. On the 23rd the condition of the limb was very satisfactory and the rubbing was discontinued. The wound healed readily except for necrosis of a small area of skin. The temperature reached its highest point (100.4° F.) on the 26th and fell next day to normal. The man was discharged on Nov. 9th.

The aneurysm after removal measured three and a half inches in its vertical diameter and three inches in its greatest transverse diameter. It involved the common, superficial, and deep femoral vessels. The external iliac artery above the point of origin of the deep epigastric branch was entirely occluded, as was the superficial femoral artery at the point of ligation. The deep epigastric and profunda arteries were dilated, and coming off the back of the aneurysm were three vessels, probably the external and internal circumflex and the first perforating arteries. The interior of the aneurysm was partly filled by laminated clot.

Remarks by Mr. BILTON POLLARD.—Excision is, in my opinion, the best treatment for all aneurysms situated in accessible positions and no aneurysms are more suited to that method of treatment than femoral aneurysm. With cautious dissection it is not difficult to isolate and ligature all the vessels supplying the aneurysm before they are divided. In the case now reported the aneurysm, which filled Scarpa's triangle, involved the common and superficial femoral arteries, and to some extent the deep femoral artery also. The external iliac artery had been tied some years before the patient came under my care, but pulsation returned soon after the operation; and immediately before I took charge of the case compression of the external iliac artery had been tried without success. The failure of both these methods was clearly due to the free supply of blood to the aneurysm from other vessels than the external iliac. The profunda femoris, the external and internal circumflex and the first perforating arteries all appeared to arise separately from the sac of the aneurysm and, although the external iliac artery was occluded, blood was still entering the aneurysm from the deep epigastric artery. The anterior crural nerve and its branches and the femoral vein were the only important structures endangered by the operation. The anterior crural nerve was defined just below Poupart's ligament and there was not much difficulty in separating it and its branches from the aneurysm. It was quite otherwise with the femoral vein, for it was so incorporated with the wall of the aneurysm as to be quite unrecognisable for about three inches of its course. The vein was isolated above and below, but the line of the intervening portion had to be guessed at. Whilst this part of the vein was being dissected from the sac a slit about an inch in length was made into it. The bleeding was completely controlled by a fine continuous silk suture and no further trouble resulted from the accident. The patient made a rapid recovery and when last seen six months after the operation the cure was perfect. The size of the patient's thigh was decreasing and he was no longer troubled by either weakness or swelling of the leg.

TORBAY HOSPITAL, TORQUAY.

- (1) A CASE OF STRANGULATED FEMORAL HERNIA; HERNIOTOMY FOLLOWED BY RESECTION OF BOWEL AND CIRCULAR ENTERORRHAPHY; AND (2) A CASE OF FRACTURE OF THE PELVIS FROM SLIGHT VIOLENCE, WITH NIPPING OF SMALL INTESTINE BETWEEN THE FRAGMENTS CAUSING ACUTE INTESTINAL OBSTRUCTION AND GENERAL PERITONITIS.

(Under the care of Mr. GILBERT J. ARNOLD.)

CASE 1.—On Dec. 31st a woman, aged 33 years, was sent into hospital by Dr. F. T. Thistle for operation. On admission the patient stated that for some years she had noticed a small lump in the right groin which had hitherto been painless. She was quite well on the previous day until 7 P.M., when

she began to experience great pain in the groin and this was followed by severe vomiting and a sleepless night. On examination there was found a small tense hernia of the size of a Tangerine orange, occupying the right femoral canal. Mr. Arnold saw her when she entered the hospital and did not employ taxis but had her prepared for operation, which was commenced one hour after admission and 19 hours from the onset of ileus. Local infiltration anaesthesia was employed, a $\frac{1}{2}$ per cent. isotonic novocaine solution containing suprarenin being used. The sac was dusky in colour and contained a loop of small intestine and a small piece of adherent omentum. The bowel was dark and congested, with loss of polish, but by no means gangrenous. The narrow tightly constricting neck of the sac was cautiously nicked with a blunt bistoury sufficiently to relieve strangulation and to enable the bowel at the seat of constriction to be drawn down and examined. Immediately this was done a slight leakage of the liquid intestinal contents was seen at the point where the bowel was compressed against the sharp edge of Gimbernat's ligament. The parts were cleansed with hot saline solution and the small necrotic opening in the softened friable bowel was invaginated and closed with a few Lembert's sutures. However, the appearance and behaviour under stimulation with hot saline solution of the involved three-inch loop of small intestine contrasted badly with the healthy bowel beyond and Mr. Arnold had no hesitation in deciding that it was unsafe to return it. The strangulated knuckle was divided through its centre and two small-sized Paul's glass tubes were tied into the open ends, the parts being carefully isolated with sterile gauze and the operation concluded by one or two sutures which served to secure the intestine and glass tubes in the wound. The patient vomited a considerable quantity of faecal fluid during operation, but there was no shock during or after its progress. Three hours later, as the amount of intestinal drainage that had taken place through the glass tubes was small, Mr. Arnold passed into the intestine by means of a catheter and funnel some warm normal saline solution, and this was quickly followed by a free discharge from the tube in the afferent piece of bowel which was received into an attached waterproof bag.

A second operation was performed on Jan. 2nd (two days after the herniotomy), the patient having greatly improved and taken a fair amount of nourishment. Mr. Arnold removed the Paul's tubes and inserted some gauze within the open ends of the bowel, and again operating under the same local analgesia the femoral wound was enlarged into the inguinal canal by division of Poupart's ligament. The affected loop of small intestine, together with healthy bowel beyond, was then readily brought outside the abdomen and surrounded with sterile gauze. Healthy bowel was then occluded by double ligatures of rubber drainage-tube four inches on each side beyond the open ends. Its mesentery was ligated with sterile catgut and approximately eight inches of small intestine were removed. An end-to-end anastomosis was then effected by an inner row of interrupted sutures of No. 0 catgut, not including the serous coat, the sutures being tied with the knots within the lumen of the bowel and particular care being taken of the mesenteric border. An outer row of fine Lembert's sutures, using fine silk and cambric needles, completed the union, which was accomplished without narrowing. The ligatured mesentery was folded on itself and secured thus with a few stitches in order that no hole should be left at the site of the anastomosis and possibly give rise to future trouble. The bowel was returned. The divided Poupart's ligament and the femoral canal were then methodically sutured and the wound was closed round a small gauze drain. Recovery was quick, complete, and uneventful.

CASE 2.—A woman, aged 76 years, was seen on Jan. 8th, in consultation with Dr. J. U. Huxley, and immediately sent into hospital as a private patient. She had recently been through a dangerous illness under Dr. Huxley's care suffering from bronchitis and a weak heart. She had formerly worn a truss for a right femoral hernia. Two days prior to admission she was discovered by her daughter on the floor in her bedroom. The patient, who had been confined to her bedroom when the accident occurred, stated that she had tripped over the leg of a chair. There were no bruising and no evidence of injury to the femur or hip-joint. Severe abdominal pain with frequent vomiting rapidly set in. On admission the condition of the patient was extremely bad. Her thin abdomen was greatly distended and did not move with respiration. There

had been treated for two months.

On admission to University College Hospital on Sept. 22nd, 1906, he was found to be a heavily built, well-nourished man. In the left groin was a swelling which filled Scarpa's triangle and on the surface of this just below Poupart's ligament was a prominence the size of a walnut. The latter was ill-defined above but sharply outlined elsewhere. The skin over it was normal. There was slight but definite expansile pulsation in the superficial prominence but no pulsation could be detected in the main mass of the swelling. The pulse in the artery below was weaker than on the right side and was slightly delayed. Pressure on the external iliac artery led to diminution in the pulsation of the aneurysm but it was impossible completely to control it. Immediately above Poupart's ligament was the oblique scar of the previous operation. The cedema of the leg had subsided as the result of rest in bed, but the whole of the left thigh was much bigger than its fellow. No other aneurysms could be found. The heart's impulse was very weak and a double murmur was present at the apex. The second sound was considerably accentuated. A moderate degree of arterio-sclerosis was present. On Oct. 4th continuous digital compression of the external iliac artery was carried out for eight and a half hours. No effect on the aneurysm was perceptible. On the 19th a vertical incision was made downwards from the old scar for about nine inches. The surface of the aneurysm was exposed and cleared and it was then found that the above noted prominence was a secondary dilatation of the large mass which lay more deeply. The mass was first cleared on the outer side, the anterior crural nerve being exposed and held aside. The parts surrounding the aneurysm were greatly matted together and after a prolonged dissection the deep circumflex iliac artery was found and ligatured and the external iliac artery was recognised. In the process of clearing it the deep epigastric artery was wounded. It was ligatured, the external iliac artery being secured above its point of origin. The superficial femoral artery was then exposed and ligatured below the aneurysm. Even after this stage the aneurysm still pulsated. It was then found that the femoral vein was closely incorporated with the sac of the aneurysm on the inner side. Part of the sac was therefore cut away and left attached to the vein, and the aneurysm was rapidly turned downwards and removed. Several large vessels were involved at the back of the sac but they were readily controlled by forceps. It was then found that a longitudinal wound about three-quarters of an inch in length had been made in the femoral vein. The rent was closed by a continuous suture of fine silk. Immediately below this wound a large vein, probably the profunda, entered the main vein. All divided vessels were then ligatured and the skin wound was partly closed, a drainage-tube being introduced.

With regard to the occurrence of pigmentation, if the suprarenals were removed in animals pigmentation did not occur, but if they were damaged or infected pigmentation of the skin developed. In rapid destruction of the suprarenals, as, for example, by carcinoma, pigmentation of the skin did not take place. He referred to a case in which the solar plexus was alone involved and the pigmentation was on the trunk rather than on the peripheral portion of the limbs. The more rapid the disease the less the pigmentation.

MEDICAL SOCIETY OF LONDON.

Surgical Affections which Simulate Appendicitis.—Cases of Goitre removed under Cocaine Anæsthesia.

A MEETING of this society was held on April 22nd, Mr. C. A. BALLANCE, the President, being in the chair.

Mr. H. J. WARING read a paper on Some Surgical Affections of the Right Iliac Fossa which Simulate Appendicitis. He would, he said, restrict his remarks to the actual conditions which had come within his own personal experience. The main symptoms of all these conditions were pain in the right iliac fossa of sudden onset with nausea or vomiting. A series of cases were then narrated illustrating the following conditions which had been mistaken for acute or subacute appendicitis: (1) acute infective osteomyelitis of the ilium (acute necrosis); (2) secondary infection of tuberculous lymphatic glands in the right iliac fossa; (3) septic infection of the right broad ligament or Fallopian tube with direct extension to the right iliac fossa; (4) adeno-papilloma of the mucous membrane of the cæcum surrounding the opening of the vermiform appendix into the cæcum; (5) acute torsion of a displaced right ovary; (6) hæmatoma of the right ovary (cases of this condition had been recorded by Mr. H. W. Wilson in THE LANCET of May 26th, 1906, p. 1462); (7) hæmatoma of the right iliac fossa; and (8) intussusception of the vermiform appendix. In the diagnosis of appendicitis it was important (a) to ascertain the exact mode of onset; (b) the previous history of the patient; (c) to make a complete examination of the abdomen and pelvis; and (d) to examine the blood.—The PRESIDENT had met with instances of the first class of cases, and he instanced the case of a boy, eight years of age. He had also seen appendicitis simulated by suppuration and calcification of the lymphatic glands in the mesentery and by extra-uterine gestation. Whenever the end of the appendix was located in the pelvis considerable difficulty in diagnosis was liable to occur.—Mr. ALBERT CARLESS remarked on the difficulties which might arise when appendicitis was mistaken for other morbid conditions. He narrated a case of twisting of the pedicle of an ovarian dermoid which had been mistaken for appendicitis, and referred to perityphlitis, typhlitis (without involvement of the appendix), and suppuration of the kidney as conditions in which a similar mistake might be made. The situation of the pain and tenderness was not, in his experience, of very much aid in the diagnosis.—Dr. F. DE HAVILLAND HALL referred to the case of a girl, aged 12 years, in whom a twisted ovarian pedicle was mistaken for appendicitis.—Mr. A. E. J. BARKER had met with illustrations of all but one of Mr. Waring's groups of cases. He had also met with cases of torsion of omentum, hæmatoma of the broad ligament, perforated gastric ulcer, stone in the kidney, and retrocæcal hernia simulating appendicitis.—Mr. WARING replied.

Mr. J. LYNN THOMAS communicated a paper entitled "A Series of Cases of Goitre removed under Cocaine Anæsthesia" which will be found in *extenso* at p. 1143 of the present issue of THE LANCET.—Mr. BARKER had operated upon a considerable number of these cases and all of them had been done under cocaine anæsthesia. Cocaine was almost a thing of the past. He preferred β eucaine with a slight addition of adrenalin. It was better to strap down the patient's limbs, especially in nervous patients. Professor Kocher did not apparently produce anæsthesia of the deeper parts but this could be accomplished by proper procedure and waiting a sufficiently long time after the injection before the operation. The formula used consisted of eucaine 0.02 per cent. with adrenalin 1 in 200,000, of which an average of three and a half ounces was injected. It was better to inject more till all the œdema had subsided.

LIVERPOOL MEDICAL INSTITUTION.

Suppurative Otitis.—Extroversion of Intestinal Mucous Membrane.—Fracture of the Humerus.—Empyema.—Abnormal Conditions within the Chest Wall.

A MEETING of this society was held on April 18th, Mr. FRANK T. PAUL, the President, being in the chair.

Mr. E. M. STOCKDALE read a note on Chronic Suppurative Otitis Media, with special reference to surgical treatment, the clinical material being a series of cases which included 60 radical mastoid operations. He drew attention to the importance of skin grafting in certain circumstances and mentioned the case of a "bleeder" in which frog skin had been used with an excellent result. A case was related in which an infant, eight months old, had suffered from a discharge from the left ear for seven months. Exploration revealed the fact that almost the whole of the mastoid and petrous portions of the temporal bone were necrosed. Removal of the diseased bone brought into view an extensive surface of dura mater covered by unhealthy granulations both in the middle and posterior fossæ. A considerable portion of the lateral sinus was exposed and the internal carotid artery could be seen as it ascended to enter the skull. His experience showed that the hearing was often improved by the radical operation. His cases demonstrated that the danger of allowing the disease to run its course was much greater in every respect than the risk of even the radical operation.—Dr. W. MILLIGAN said that the great difficulty in practice was to determine the extent of the disease in the accessory cavities of the ear. An exploratory operation, followed if need be by a complete radical operation, was frequently indicated in chronic cases. He found, as Mr. Stockdale had said, that after many radical operations the hearing power was distinctly better than it had been prior to operation.

Mr. G. P. NEWBOLT showed a case of Extroversion of Intestinal Mucous Membrane after operation. The case in its original condition had been shown before the society on Oct 23rd, 1906. The abdominal wall was now completely restored with the exception of a small sinus from which a little mucus sometimes escaped.

Mr. RUSHTON PARKER read a note on Compound Fracture of the Humerus and showed a patient whose upper arm had been severely lacerated and the humerus broken transversely. Mr. Parker explained by means of lantern slides the way in which the ends of the bone had been kept in position by means of a sheet-iron twisted back-splint and two smaller lateral ones without having recourse to wiring. An excellent result had been secured. Radiographs were shown exhibiting the stages of callus formation.

Dr. W. B. WARRINGTON read notes of three cases of Empyema of an Unusual Nature. In the first patient, who was a boy aged 17 years, the empyema was latent for over a year. There were very few symptoms and spontaneous recovery followed rupture of the empyema through the lung. In the second case the empyema followed pneumonia and was limited to the upper part of the thorax. The patient had six years previously had an empyema which had been opened in the usual infra-scapular site. The third patient was a boy, aged eight years. The physical signs were unusual; they comprised extended hyper-resonance, with amphoric breathing, coin sound metallic tinkling, depression and rotation of the liver. There was an area of movable dullness in the lateral and basal regions of the right thorax. Dr. Warrington considered that the symptoms were such as could be caused by air and fluid in the pleural cavity, though evidence as to the cause of a pneumothorax was wanting.

Dr. JOHN HAY read notes of three Cases illustrating Some Points in the Diagnosis of Abnormal Conditions within the Chest Wall. The first case was one of actinomycosis of the lung simulating pulmonary tuberculosis and terminating fatally. The patient, who was a girl, aged 16 years, suffered from great dyspnoea, cough, and anæmia, and had been losing weight for six months. Her pulse-rate was 160 and there were signs of consolidation at the apex of the right lung. Three weeks later numerous abscesses had formed. Actinomycosis of the lung was diagnosed with a secondary actinomycotic pyæmia and this diagnosis was verified by subsequent examination of the pus. The second case was one of centrally placed empyema not discovered by frequent exploratory aspirations. The patient, who was a woman,

was a slight fullness over the right femoral canal. Vomiting of very offensive material was frequent. The pulse-rate was 120, weak, thready, and intermittent. There had occurred some slight loose actions of the bowels during the previous sleepless night. Acute intestinal obstruction was manifest and Mr. Arnold was rather of the opinion that the cause might be found in a Richter's hernia in the right crural canal. It was obvious, too, that operation under general anaesthesia entailed a great risk of death on the table. The patient, however, expressed herself as willing to face the risk of operation rather than endure further misery and acute suffering.

By means of the same local anaesthesia as was used in the previous case the old femoral hernia was rapidly explored but only a narrow empty sac communicating with the general peritoneal cavity was discovered. The abdomen was then quickly and painlessly opened in the linea alba above the pubes. Much brown turbid serum escaped and there were flakes of lymph on the deeply congested and greatly distended coils of small intestine. Next, some pale collapsed small intestine was discovered and the seat of obstruction was traced to the right side of the pelvis below the brim where the bowel was immovably fixed. An unsuccessful attempt was then made to discover and remove the cause, but no amount of gentle manipulation with the gloved fingers sufficed to liberate the bowel, the distended coils of which were weakly agglutinated at this situation. Concluding that the case was a strangulated obturator hernia irreducible from the abdomen Mr. Arnold returned to the femoral wound and after infiltrating the deep structures superficial to the upper and outer portion of the thyroid foramen by blunt dissection through the pectineus muscle there was exposed a small dark nodule of tissue recognised as a bit of intestine lying against the horizontal ramus of the os pubis. Examination with a finger in the abdomen at the spot where the bowel was fixed revealed a rough irregularity of the bony pelvis due to fracture of the horizontal ramus near the body of the os pubis. Some force was required to separate the bony fragments and to liberate the lacerated intestine which was held as in a vice. The crushed and nearly severed piece of bowel was brought outside; its division was completed and Paul's glass tubes were tied in the ends. The pelvis was flushed out with hot saline solution and the abdominal incision was closed sufficiently to secure the bowel *in situ*. The femoral wound was closed round a gauze drain. Very offensive faecal vomiting occurred repeatedly during this trying operation, unusually difficult owing to this unexpected traumatic fixation of the gut. Unfortunately, the patient survived barely an hour after the completion of the operation.

Remarks by Mr. ARNOLD.—These two cases were in hospital at the same time and both, I venture to think, present features of considerable interest.

Case 1 is a good example of the rapidity with which grave changes occur in the contents of a strangulated femoral hernia owing to their severe constriction at the neck of the sac. It will be noted that within 19 hours of the onset there was a virtual perforation of the bowel at the neck of the sac and the vitality of the knuckle was so impaired as to render its return unjustifiable. Even gentle taxis at this stage might have resulted disastrously. With regard to the local infiltration anaesthesia, the patient bore her second operation extremely well and felt but little inconvenience throughout the whole procedure, which was conducted without haste, extra time being of no moment. Her pulse was good and only 88 at the conclusion of the operation. At the first operation, when she was acutely ill and therefore intolerant of any manipulation, she complained of being hurt but not until after the sac had been exposed and opened.

As regards Case 2, it is remarkable that a fracture of the brim of the pelvis should have resulted from what seems a comparatively slight degree of violence in a woman who had not previously shown signs of fragilitas ossium. There was no one with her at the time of her fall. It is probable that the small intestine was caught, crushed, and fixed between the pubic fragments during their momentary separation at the time of the accident. On the other hand, the possibility of this disastrous incident having occurred shortly after the accident owing to movement taking place between the fragments cannot with certainty be excluded. Such an accident is probably of extreme rarity.

Medical Societies.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

The Diagnosis of Addison's Disease.

A MEETING of this society was held on April 23rd, Mr. J. WARRINGTON HAWARD, the President, being in the chair.

Dr. OTTO F. F. GRÜNBAUM read a paper on the Diagnosis of Addison's Disease. He said that the chief signs and symptoms of Addison's disease were asthenia and pigmentation, but either or both of these might be present in many other diseases and frequently the early stages were difficult of diagnosis. Some eight years ago he found that oral administration of suprarenal extract to normal individuals did not cause a rise of blood pressure. Since then evidence had accumulated to show that when a rise of pressure followed the exhibition of the drug by the mouth it indicated suprarenal inadequacy. In doubtful cases the blood pressure was determined accurately and then three-grain doses of suprarenal extract were administered thrice daily for three days. The blood pressure was again estimated and a distinct increase was very suggestive of Addison's disease provided there was no valvular lesion of the heart. Often it was possible to decide that the lesion of the adrenals was tuberculous by suitable examination of the opsonic index of the blood after inoculation with tuberculin.

Dr. H. D. ROLLESTON said that there was very great difficulty in the diagnosis of the early stages of Addison's disease and the method suggested by Dr. Grünbaum was most valuable. He knew that the administration of suprarenal extract raised the blood pressure in cases of Addison's disease, but he had not used it as a diagnostic method. The question of Addison's disease was often raised on the presence of pigmentation only and the condition of the blood pressure was a valuable aid in diagnosis. A condition of suprarenal inadequacy had been described and it would be of interest to find out whether in such cases the blood pressure was raised by the administration of suprarenal extract. In a patient who was given suprarenal extract both during and after pneumonia no rise of blood pressure occurred. He referred to the disappearance of the radial pulse in cases of Addison's disease and said that in one case he had noticed this 36 hours, and in another 48 hours, before death. Pigmentation of the mucous membrane of the mouth occurred only when there was a source of irritation as by bad teeth. The absence of pigmentation in this situation was not of importance in the diagnosis of the disease. He referred to a case in which the diagnosis of Addison's disease had been made on the presence of pigmentation alone more than 30 years ago. The man has exhibited no other symptoms and is still a strong athletic individual.

Dr. F. PARKES WEBER referred to a case in which very prolonged asthenia followed an attack of influenza. From this complete recovery took place and the patient went to India, where he contracted malaria. He then suffered from exhaustion and weakness and pigmentation of the skin was noticed. He had frequent syncopal attacks, in one of which he died. At the necropsy both suprarenals were found to be caseous and matted together across the aorta. He thought that in cases in which prolonged asthenia was present the possibility of Addison's disease should be borne in mind.

Dr. HOWARD H. TOOTH suggested that bromide sometimes gave rise to pigmentation of the skin and he asked Dr. Grünbaum whether he had met with such a case.

Dr. W. EWART said that there was great variation in the symptoms in cases of Addison's disease; in one variety asthenia was the prominent symptom, whereas in another pigmentation was the most marked character. He suggested that the variation in symptoms might depend upon the different portion of the suprarenal affected. He thought that the cases exhibiting much pigmentation were less severe than those with asthenia. He related a case in which pigmentation had existed for many years.

Dr. GRÜNBAUM said that he had never seen a case in which he could prove that pigmentation was due to bromide.

Axial Rotation of Ovarian Cysts during Pregnancy. The patient, aged 27 years, was suddenly seized with severe abdominal pain and vomiting when she was three and a half months pregnant. A tense cystic tumour occupied the right side of the abdomen and a smaller cystic mass was felt on the left side, the uterus occupying a central position. Abdominal section was performed. Both ovaries were converted into dermoid cysts, each of which had undergone acute torsion. The tumour on the left side had ruptured and the peritoneal cavity contained blood. Both tumours were removed and 15 days later miscarriage occurred spontaneously. The foetus had evidently been dead for some days. Bilateral ovariectomy, said Dr. Lea, had now been performed during pregnancy in at least 60 cases, and it was remarkable that in the great majority the pregnancies had continued to the full term.—Dr. T. B. Grimsdale (Liverpool) communicated the case of a patient, aged 29 years, who had never menstruated, but had complained of pain in the back, which had lasted for two days each month. Her general health was good. There was no cough and no abnormal signs could be detected in the lungs. There were old healed scars in the right groin, suggesting old suppurating glands, and a depressed healed scar on the inner side of the lower part of the right thigh, suggesting old necrosis of the femur; there were also some healed scars over the right tibia. The patient could not give any account of these scars. She was well developed and apparently was a strong healthy woman. There was no abdominal tumour. The vaginal examination was made under an anæsthetic. The uterus was found to be somewhat enlarged and moveable. There was a definite elongated swelling to the left of the uterus. An endeavour to pass the sound failed; it would only pass for three-quarters of an inch. The diagnosis of malformation of the uterus with possibly some retention of blood was made. The abdomen was opened and the uterus and Fallopian tubes were removed; the vermiform appendix was adherent to the right tube, and also to the upper part of the rectum into which it had opened. Both Fallopian tubes were distended with thick pus. The uterus contained caseous pus in its cavity, which was also disseminated through its walls. The case was one of tuberculous disease of the uterus and appendages causing primary amenorrhœa.

CHELSEA CLINICAL SOCIETY.—A meeting of this society was held on April 16th, Dr. J. D. E. Mortimer, the President, being in the chair.—Dr. J. H. Dauber read a paper on *Some of the Factors which Contribute to Success in Abdominal Operations*. He said that in malignant cases the mortality was necessarily great; otherwise old people bore operations well. The mental condition was most important. Pessimistic remarks should always be carefully avoided and all the surroundings should be encouraging. If kept long in hospital the courage of patients was liable to evaporate and they refused to be operated on. Obviously any inflammatory condition should be allowed to subside if possible. An even temperature before, during, and after operation was most essential, and for the sake of others the patient should not be returned to the ward till the effects of the anæsthetic had passed off. The disinfection of inhalers and warmth after operation were very essential precautions. Wrapping in cotton-wool was an excellent practice. No patient should have the stomach empty for more than three and a half hours before operation. Asepsis must, of course, be absolute and preferably by the agency of heat, and all concerned must be constantly on their guard against septic loopholes. There was no object so delicate, so susceptible to septic infection, as one that had just been sterilised. Patients trusted their lives to them and it was treachery to neglect the elimination of any possible risk. A heavy-handed operator was distinctly unfavourable to a successful operation, and rapidity of operation was as important as ever it was. An operation which lasted more than an hour was always dangerous from mere lapse of time. After this period exhaustion set in and the patient was liable to sudden heart failure. Assistants should be as few as possible. The risk of sepsis increased with numbers. After operation it was essential to relieve thirst either by giving water to drink or by rectal injections. Occasional movements from side to side relieved the intolerable backache. Morphine was occasionally necessary, and purgatives or injections frequently, especially when the bowels were distended with flatus. Much of the success of operations depended on the commissariat. Patients required tempting and coaxing when convalescing or they would

well-known dictum, "A patient convalesces on his belly." Besides mending the injured part they must patiently endeavour to restore the disordered function.—Mr. J. Foster Palmer then read a paper on the *Treatment of Apoplexy*. There were only two methods of treatment, he said, the active and the passive. Any middle course was dangerous—fatal. As they were not yet supplied with appliances for a sufficiently accurate diagnosis to justify operative proceedings they must steadily adhere to the passive treatment. The indications, therefore, were chiefly negative, warnings against hostile dragons and venerable superstitions. Bleeding was now, perhaps, practically non-existent; but strong aperients, which were not yet extinct, were even more dangerous. Whatever the cause the patient would often go on well until an aperient was given and then he would die almost immediately. The nerves supplying the intestinal canal required rest as well as the nerves of motion, of sensation, and of special sense. It was better to leave the bowels inactive for a fortnight or more than to irritate them in the slightest degree. Blisters, too, were objectionable in a lesser degree as unnecessarily exciting the nerves of sensation. Ice to the head only drove the blood from the surface to the interior and when applied to the back of the neck increased congestion in the brain by dilating the blood-vessels. Position was all-important. Nothing was so fatal as to allow a patient to lie on his back. The powerless muscles allowed the tongue to fall back in the pharynx; the entrance of air into the lungs was hindered, stertor resulted, and apnoea followed in its train. This was generally relieved by placing the patient on his side, preferably the paralysed side, though bed-sores must be carefully watched for. Possibly in some cases the addition of oxygen to the inspired air might be of advantage. Rest was the great desideratum. Rest for the injured brain, rest for the nerves of motion and sensation, rest for the nerves controlling secretion and digestion, and rest for the nerves of special sense would include the objects chiefly aimed at in the treatment of this severe lesion. In regard to prevention the importance of calcification as a factor in arterial degeneration suggested the avoidance so far as possible of lime salts by all above middle age. Mineral waters containing lime were especially dangerous, as they also contained free carbonic acid, which rendered it more soluble. Still more dangerous were medicines containing lime salts.

LEEDS AND WEST RIDING MEDICO-CHIRURGICAL SOCIETY.—A clinical meeting of this society was held on April 12th, Dr. Augustus H. Hampton being in the chair.—Dr. A. G. Barrs and Mr. R. Littlewood showed a case in which a tumour pressing on the spinal cord at the level of the ninth dorsal vertebra, and causing complete paraplegia, was removed by laminectomy. Sensation in the limbs returned as soon as the patient regained consciousness after the operation; in a fortnight there was perfect control over the sphincters and improvement was still proceeding.—Mr. A. L. Whitehead showed a case of extensive Mastoid Disease with extradural abscess and much external pachymeningitis successfully operated upon. There had been an old-standing otorrhœa but the acute condition supervened upon an attack of influenza.—Mr. R. L. Knaggs showed a case of Duodenal Fistula in the right loin in a girl aged 17 years. In August, 1906, she had an acute attack of abdominal pain; from October, 1906, to January, 1907, she had pyrexia and induration in the right psoas region. This was opened and was thought to be a psoas abscess, until two months later food began to come through the fistula shortly after being swallowed. For various reasons the fistula was regarded as being probably of duodenal origin, an opinion concurred with by the meeting.—Mr. J. F. Dobson showed a case of Spinal Caries treated on a Bradford's wire frame for six months with much improvement.—Dr. W. H. Maxwell Telling showed two cases of Anæmia Splenica Infantum in twins; also a third case in which complete recovery had taken place. He also showed a case of Chronic Favus refractory to the ordinary treatment for ten years. It was proposed to treat it by the application of x rays.—Dr. J. Gordon Sharp showed a girl, aged five years, in whom Motor Aphasia with Left Hemiplegia developed subacutely. The patient was right-handed. In two months right hemiplegia was ushered in by a convulsion. The right side was now well but some weakness of the left side persisted.—Mr. T. H. Fox exhibited a Cretin showing marked improvement under thyroid treatment continued for three years. The case was interesting in that a particular brand of tabloids produced improvement for six months and then became inactive. A similar result was obtained with

aged 35 years, was admitted into the Stanley Hospital five weeks after a difficult confinement suffering from pain in the chest, pyrexia, and cough. Ten days before admission she had a rigor and pain in her left side. Exploration of the chest gave a negative result. Later the spleen was found to be enlarged, the temperature remained elevated, and there was leucocytosis. The Widal reaction was negative. Exploration on two more occasions failed to locate pus, but finally it was found below the costal margin and the abscess was drained. The patient died the next day. The necropsy revealed an empyema in front of the root of the right lung adjacent to the pericardium. The pus had travelled down through the diaphragm and formed a subphrenic abscess. The recent delivery, the rigors, the continued high temperature, the normal position of the apex beat, the enlarged spleen, the severe anemia, and the failure to strike pus all added to the difficulties. The third patient was a man, aged 36 years, suffering from marked dyspnoea, cough, recurring hæmoptysis, and cardio-pulmonary murmur audible at the mouth, but with slight physical signs. He had contracted syphilis when aged 27 years. He first began to suffer from lung symptoms five years ago. The x rays showed some fibrosis, especially at the root of the right lung, but the apices were clear; the right side of the diaphragm was limited in its movements. There was no history of night-sweats or of any abnormal temperature and there was no expectoration. Under treatment by mercury and potassium iodide the dyspnoea had greatly diminished, the cough had almost disappeared, and the man's weight had increased, but the cardio-pulmonary murmur remained unaltered.—Dr. T. R. GLYNN referred to a case of actinomycosis apparently commencing in the lung. The patient was an elderly man whom he had seen with Dr. R. Thacker King. The early symptoms were harassing cough with expectoration of blood and sanguineous mucus; a tumour in which the ray fungus was found subsequently formed on one of his legs. The mode of infection was not discovered.—Dr. T. R. BRADSHAW, in discussing Dr. Warrington's cases, drew attention to the difficulty of distinguishing between empyema at the apex and a pulmonary abscess pointing in the same situation. He narrated the case of a man who had pneumonia of the right apex. After a week fever was noticed in the breath for one day. A few days later a prominence was noticed below the right clavicle and on being punctured it yielded foetid pus. Operation showed that the abscess was in the lung and that it contained a large slough which was removed. Recovery was satisfactory.—Dr. N. P. MARSH, Sir J. BARR, Dr. R. J. M. BUCHANAN, Dr. G. A. CRACE-CALVERT, Mr. R. W. MURRAY, Mr. T. O. LITLER JONES, and the PRESIDENT also took part in the discussion.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF MEDICINE.

Exhibition of Cases and Specimens.—Addison's Disease.—Cerebro-spinal Fever.

A MEETING of this section was held on April 5th, Dr. JOSEPH M. REDMOND, the President, being in the chair.

Dr. DEMPSEY exhibited a case showing Unusual Nervous Symptoms which he regarded as the result of multiple spinal sclerosis.

Dr. WILLIAM A. WINTER showed a man suffering from Aneurysm of the Thoracic Aorta. There was loss of voice owing to paralysis of the right vocal cord. There were no other physical signs except a limited area of dullness on percussion and some difficulty in deglutition. On examination with x rays a definite pulsating tumour could be seen to the left of the sternum.

Dr. ALFRED R. PARSONS read a paper on Pseudo-renal Colic. It was an account of a case which had long defied diagnosis but had ultimately been correctly diagnosed as an aortic aneurysm. The specimen was exhibited.

Dr. DEMPSEY read an account of a case of Addison's Disease of unusually short duration.

Dr. GEORGE PEACOCKE read a paper on Cerebro-spinal Fever occurring in a Child the subject of Lymphatism. The patient, who was a girl aged five years, died 11 hours after the onset of the symptoms. The chief symptom consisted in repeated attacks of convulsions. There was only slight retraction of the head. Kernig's sign was absent. There

were several purpuric spots of irregular size present on the legs and arms. The necropsy revealed the presence of lymphatism characterised by enlarged and bulky thymus gland, enlarged mesenteric glands, hypertrophied Peyer's patches and solitary follicles, and prominence of the Malpighian corpuscles on section of the spleen. Cerebro-spinal fluid removed by lumbar puncture after death was turbid, the turbidity being due to leucocytes. Weichselbaum's meningococcus was found.—Dr. T. P. O. KIRKPATRICK asked if a diagnosis of the condition of lymphatism had been made before death and if there was any way by which it could be recognised. He said that the condition had been found in a number of cases in which sudden death had occurred during the administration of anaesthetics for operations and the diagnosis of lymphatism before death was a matter of practical importance.—Professor ARTHUR H. WHITE said that, in his opinion, it was possible that the condition of lymphatism was connected with the question of infection. Most of the patients who died from cerebro-spinal meningitis had had trouble with adenoids and a good deal of lymphoid tissue at the back of the nose, and it was possible that they became infected in that way. The organisms existed in some healthy people. At the back of the nose there were many kinds of diplococci, several of which were difficult to distinguish from the organism found in cerebro-spinal fever. The only case in which he had seen a necropsy made during the present outbreak had the condition which Dr. Peacocke called lymphatism.—Dr. PEACOCKE, in reply, said that the idea of lymphatism did not occur to him during the patient's life. The symptoms before death were practically nil and the only physical sign likely to be detected would be the presence of a very large thymus showing dullness.

NORTH OF ENGLAND OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.—A meeting of this society was held at Manchester on April 19th, Dr. E. O. Croft (Leeds), the President, being in chair.—Dr. D. Lloyd Roberts (Manchester) exhibited a Malignant Ovarian Tumour removed by abdominal section from a multiparous widow, aged 65 years. The menopause had occurred 20 years before and an abdominal swelling had been noticed for eight months. There had been no pain or loss of flesh. The physical signs were those of an ovarian cyst with ascites. On account of the enfeebled condition of the patient a preliminary paracentesis abdominis was performed followed by ovariectomy four weeks later. The opposite ovary was cystic and was therefore also removed. Recovery was uneventful. Microscopically the growth was an adeno-carcinoma.—Dr. W. E. Fothergill (Manchester) showed Compressed Swabs for Use in Abdominal Sections in Private Practice.—Dr. W. Blair Bell (Liverpool) showed a specimen of Sarcoma of the Ovary removed from a woman, aged 55 years, 6 para, and who was nine years past the menopause. Microscopically it was shown to be a large spindle-celled sarcoma, the cells composing the tumour having large oval nuclei. There was a somewhat unusual amount of intercellular substance.—Dr. Arthur J. Wallace (Liverpool) related a case in which a large Fibroid had been Removed with the Uterus from a woman, aged 53 years. The tumour had burrowed between the layers of the left broad ligament and up beneath the peritoneum covering the posterior wall of the abdomen, and during operation the lower part of the descending colon and its sigmoid flexure had to be stripped off the growth. 40 hours after operation the patient began to have a continuous discharge from the rectum of dirty, watery, slimy fluid, very occasionally streaked with blood. All general and local remedies proved ineffective, the discharge persisting until the sixteenth day. Dr. Wallace was inclined to think that the cause of the condition was damage to the nervous supply of the colon during operation, with resulting vaso-motor paralysis and trophic disturbances in the wall of the bowel involved and sepsis within its canal. Six weeks after operation a temperature of 104° F. suddenly developed and for a week it was rarely below 100°. The patient's general condition steadily improved during this time and no cause could be discovered for the high temperature. The operation wounds had healed by first intention and there had been no return of the diarrhoea. Now, in four months after the operation, the patient was in good health but she still had elevations of temperature for which there was no apparent cause.—Dr. Arnold W. W. Lea (Manchester) related a case of Bilateral

Morgagni.—Dr. H. J. Davis exhibited a boy, aged 12 years, who, according to his mother's statement, had never spoken. The boy was unable to protrude the tongue. He was very intelligent and he heard and understood perfectly. He could hum songs in tune but could not speak a word (aphemia). At the age of three years, it was stated, he had right hemiplegia.—Dr. J. Bonelan exhibited a patient with Destruction of the Columella of the Nose occasioned either by syphilis or by lupus. In view of there being some evidence of active disease he decided to observe the case a little longer before doing anything of a surgical nature.—Dr. J. Dandas Grant exhibited a case of Pharyngo-keratosis (mycosis) improving under application of salicylic acid in sulpho-riolate of soda. The patient had been under this treatment for 12 months.—The President said that he had tried salicylic acid for mycosis but that he did not have much faith in the treatment.—Dr. F. de Havilland Hall commented on the way that keratosis, like warts elsewhere, would sometimes clear up in an astonishing way.—Sir Felix Semon inquired why keratosis should be treated at all locally, inasmuch as it always got well of itself. He hoped the profession would recognise that keratosis occurred when the patient was run down, and that it would disappear under a change of air and tonic treatment and that no local treatment was necessary.—Dr. Grant, in reply, expressed himself in agreement with Sir Felix Semon. He had put before the patient the fact that the appearance of the throat was of no significance, and he thought the discomfort that the patient had gone through in using the remedy was out of proportion to the result. He would not recommend the treatment in every case of the kind.—Dr. W. Jobson Horne exhibited a macroscopic specimen of Lympho-sarcoma of the Mediastinum. The growth had caused extensive obstruction, almost obliteration, of the oesophagus without any breach of the mucous membrane. The larynx presented oedema localised to the right arytenoid region; immediately below the oedema, in the fold passing down between the cartilages of Santorini and Wrisberg, was a small ulcer. The points of interest were the unusual extent of the oesophageal obstruction and also whether the localised oedema of the larynx was occasioned by local infection or was secondary to obstruction caused by the mediastinal growth.

NOTTINGHAM MEDICO-CHIRURGICAL SOCIETY.—

A meeting of this society was held on April 17th, Mr. E. Powell, the President, being in the chair.—Reference was made to the death of Dr. W. H. Ransom, one of the founders of the society, and a resolution of sympathy with the members of his family was moved by the President, seconded by the President-elect, Dr. L. W. Marshall, and adopted unanimously.—Dr. M. Parry-Jones (Derby) read a paper on some cases of Pneumothorax. As far as the causes could be classified 90 per cent. were due to pulmonary tuberculosis, 8 per cent. to gangrene and acute inflammatory conditions, and only 2 per cent. to various rare causes, such as severe pleurisy, empyema, enteric fever, hydatid, or aneurysm. Pneumothorax was very rare as the result of chest injuries, even with fractured ribs or stabs. A case of pneumo-hemothorax the result of injury without any fracture was narrated. The onset of pneumothorax was most variable and the degree of pain present, as well as the displacement of viscera, might be greatly dependent on the presence or absence of adhesions. The signs, too, might be greatly modified by the presence of fluid effusion, and in this way the tympanic area might vary in pneumothorax, which was not the case in a large vomica. In the more severe cases death might occur rapidly from shock and exhaustion, in more favourable ones the air might be rapidly absorbed without any further complication, but, on the other hand, the pneumothorax sometimes became chronic or was accompanied by serous effusion, while the pleuritic effusion might quite overshadow the pneumothorax or even rapidly become empyema. A man, aged 28 years, was shown (by Dr. Parry-Jones) illustrating apparently complete recovery from acute pyo-pneumothorax. Pus was found within a few days of the onset and the chest promptly opened. Progress was unsatisfactory, so portions of two more ribs were removed and the wound freely opened up. The drainage seemed good, but at the upper part of the space a large opening in the lung came into view leading into a vomica, from which foul pus was discharging. A drainage-tube was therefore inserted into the lung. From this time his recovery was rapid and the lung had expanded well, while there were no abnormal sounds audible.

He had gained weight, felt well, and was at work.—The paper was discussed by the President, Dr. J. H. Johnston, and Dr. F. H. Jacob.—Mr. J. C. Sale (Skegness) mentioned the case of a girl who had come under his notice where there had been 11 separate attacks of pneumothorax, and Dr. Parry-Jones replied.—Dr. Jacob read a few notes on the Treatment of Ringworm by the X rays. He showed Sabouraud's pastilles, by the aid of which epilation by one exposure was rendered safe. Reference was also made to its treatment by copper ions.

SOCIETY FOR THE STUDY OF DISEASE IN CHILDREN.—A meeting of this society was held on April 19th, Dr. O. W. Chapman being in the chair.—Dr. Chapman read notes on two cases of Glandular Fever in a mother and child.—Dr. T. R. O. Whipham showed a girl, aged eight years, who was the daughter of alcoholic parents and had developed deafness, stuttering, stridor, transient ptosis and anæsthesia, and some atrophy of the tongue. She was hypersensitive and emotional. The diagnosis lay between neurosis and disseminated sclerosis.—Dr. Whipham also showed a girl, aged 11 years, with Adherent Pericardium and Aortic and Mitral Regurgitation, due to acute rheumatism 18 months previously.—Dr. Fletcher Beach showed a boy, aged six years, with fibrous nodules over the right eye and occiput, atrophy of the left side of the face, marked curvature of the dorsal spine, and large pigmented areas on the abdomen and back. The case was considered to be von Recklinghausen's disease.—Dr. J. Porter Parkinson showed a girl, aged two and a half years, with Right Hemiplegia and Motor Aphasia. The power of speech was gradually returning after having been completely lost for a month.—Dr. F. J. Poynton showed a case of Addison's Disease in a girl, aged nine years. She had suffered from vomiting, lassitude, and fainting attacks for a year and from pigmentation of the face for a month; there was some pigmentation of the mucous membranes and the blood pressure was only 60 millimetres of mercury, but there was no anæmia.—Mr. Duncan C. L. Fitzwilliams showed the following cases and specimens: 1. A case of Multiple Abscesses in a child nine months old. There were 27 abscesses on the head, body, and limbs; a few had burst; there was no history of syphilis. 2. A girl, aged 11 years, with Congenital Absence of the Left Arm. The bones and muscles of the shoulder girdle were well developed. There was spinal curvature due to the unbalanced weight of the right arm. 3. A Siren Fœtus with a Normal Pelvis, but a solitary lower extremity, containing a thick femur below which were two partially separated bones; the bones of the paddle-like foot were normal.—Mr. G. Pernet showed a case of Erythema Iris in a child, aged three years, due to intestinal intoxication, and a case of Erythema Papulatum Hemorrhagicum in a girl, aged 15 years, stated to be a vegetarian.—Mr. Francis Jaffrey exhibited an infant, aged six months, with a Cartilaginous Tumour attached to the whole length of the nasal septum, blocking the left side of the nose and bleeding freely.—Dr. J. H. Tallent showed a child, aged two and a half years, with Double Retained Testes. When he was six weeks old a swelling appeared in the right groin but disappeared again in about five minutes, and this swelling had frequently been noted subsequently.

THERAPEUTICAL SOCIETY.—A meeting of this society was held on April 16th, Dr. T. E. Burton Brown, the President, being in the chair.—Dr. George Oliver read a paper upon Some Notes on the Control of Supernormal Arterial Pressure. He gave the leading results of his clinical observations on the management of a persistent rise in the arterial pressure by diet, baths, electricity, and other remedies. He indicated some practical suggestions furnished by physiology in the selection of apressor remedies for less or more continuous use and stated his further favourable experience of the benzene derivatives, at the same time showing that their control over persistent increments of arterial pressure was limited to the case in which the pressure rise was moderate and the vaso-motor play of the peripheral arteries was not seriously impaired.—Sir Lauder Brunton considered Dr. Oliver's paper very valuable. He thought that in cases of very high tension absolute rest in bed with quiet of body and mind was indispensable. With perfect rest, vegetarian diet, and the steady use of nitrates even cases of exceedingly high tension might be successfully treated. A salt-free diet might be useful in cases of very high tension, but it could not be continued for a length of time as it was so

another preparation; on reversion to the first a like result followed. This has happened throughout the case.—Dr. T. Churton showed a case of Anæmia Splenica Infantum in a child the subject of congenital syphilis. The spleen was enormously enlarged and five distinct notches could be felt in it. He also showed a case of Splenic Anæmia in a man of 30 years. The anæmia was of the secondary type; there had been three severe attacks of hæmatemeses during an 18 months' history.—Dr. E. F. Trevelyan showed a series of cases of Tabes, illustrating various typical and atypical features of the disease.—Dr. T. Wardrop Griffith showed a case of Ataxia of sudden onset and rapid progress. The disease commenced on Feb. 27th and rapidly spread to the arms, increasing in the legs. The Babinski phenomenon was present and varying areas of anæsthesia were present in the legs but there was no other abnormal sign. The case was regarded as probably one of disseminated sclerosis.—Mr. H. Collinson showed a case of Removal of Half the Tongue by Whitehead's method, three and a half years ago. The sub-maxillary and deep cervical glands were removed at the same time. So far there had been no recurrence.—Mr. Michael A. Teale showed a series of cases exhibiting Disorders of the Mobility of the Iris.—Mr. H. Secker Walker showed a case of Dermoid Cyst of the Eye and Supernumerary Auricles. He also showed a case of Xerosis of the Conjunctiva.—Dr. Alexander Sharp showed two cases of Tuberculous Laryngitis in the catarrhal stage.

MIDLAND MEDICAL SOCIETY.—A meeting of this society was held on April 17th, Dr. Edward Malins being in the chair.—Dr. Walter R. Jordan showed a father and two children (boy and girl) with a condition of Congenital Keratoderma affecting the Palms of the Hands exclusively. The father's father had been similarly affected. A brother of the father and a third child of the father were entirely free from the condition.—Mr. L. P. Gamgee showed a woman, aged 24 years, who for eight years had suffered from symptoms of Gastric Ulcer. She had had two attacks of hæmatemesis. The symptoms had been relieved by medical treatment but there had been a relapse each time. On July 25th, 1906, an anterior gastro-jejunostomy was done by stitching. Within half an hour of the patient's return to the ward severe hæmatemesis set in, three pints of blood being vomited within the first 24 hours after operation. This ceased and then at the end of ten days it became evident that a vicious circle had been formed, large quantities of bile-stained fluid being frequently vomited. On Oct. 20th a lateral anastomosis was done between the piece of jejunum passing up to, and that passing down from, the junction with the stomach. This resulted in cessation of the vomiting till Feb. 13th, 1907, when vomiting recurred. On March 4th the abdomen was re-opened and it was found that the jejunum, at a point just over the seat of the lateral anastomosis and at another point six inches below this, was bound down by dense adhesions. These were divided and the patient had been perfectly well ever since.—Dr. J. Douglas Stanley showed a girl, aged 12½ years, who first came under observation when ten years old on account of typical Raynaud's Disease and Rheumatoid Arthritis. At that time the joint lesion was slight. The patient was deficient in weight and stature and her mental condition was much under the average. During the two and a half years the Raynaud's disease had improved but the arthritic lesions had advanced, the hands especially showing typical characters of rheumatoid arthritis. The height and weight were now 3 feet 10½ inches and 30½ pounds. There was no evidence of enlargement of the spleen or lymph glands. Dr. Stanley discussed the possible connexion between rheumatoid arthritis, Raynaud's disease, and myxœdema.—Dr. J. G. Emanuel showed a Heart in which there was practically a Single Ventricle (the right ventricle) into which the mitral and tricuspid valves opened and from which arose the aorta anteriorly and the pulmonary artery posteriorly. Close to the opening of the aorta was a foramen which led into a small potential cavity in the wall of the ventricle, and with this cavity the aorta communicated. This therefore represented a rudimentary and functionless left ventricle and the foramen of communication between it and the right ventricle was the patent pars membranacea septi. The interauricular septum was complete. The aorta septi. The interauricular septum was complete. The aorta at its origin lay anterior to the pulmonary artery and externally there was but an imperfect separation of the aorta from the pulmonary artery. This malposition of the great vessels was explained by an irregular descent of the septum which should completely divide the primitive arterial bulb

into aorta and pulmonary artery. All the valves were well formed; the foramen ovale was closed; the ductus arteriosus was obliterated. The specimen was from a male infant, aged 20 months, who died from thrombosis of the right pulmonary artery with multiple infarcts in the corresponding lung. During life there were no cyanosis and no clubbing. The symptoms were sudden syncopal attacks. There was no thrill but a loud systolic murmur was audible all over the præcordium.—Mr. A. W. Nuthall showed a case of Mongolian Idiocy, exhibiting typical characteristic features.

ÆSCULAPIAN SOCIETY.—A meeting of this society was held on April 19th, Dr. J. R. T. Conner, the President, being in the chair.—Dr. Alexander Morison read a paper on the Nature and Management of Hypertrophy of the Heart. He said that when the heart dealing with an obstacle in the normal and easy transmission of blood hypertrophied, in just proportion to the additional work thrown upon it, it was said to be "compensated." But such a condition of "compensation" was one of a more or less uncertain state of equilibrium between obstacle and heart power and this uncertainty was proportionate to the character of the obstacle. There were certain conditions in which the compensatory hypertrophy overstepped the limits of beneficial increase. This was, no doubt, because the degree of embarrassment in the circulation was of more than average severity. It was the cor bovinum—a heart hypertrophied in a degree beyond the average—which exemplified that degree or condition of cardiac hypertrophy which ceased to be beneficial in compensation and became from its bulk an added intrathoracic embarrassment to the circulation of the blood. The effect of excessive effort was, naturally, exhaustion, and in the production of this result several factors—hæmic, neural, and muscular—were operative. That the disabled heart, sufficiently "compensated" by the hypertrophy provoked by its condition, might efficiently do its work for lengthened periods in circumstances of considerable stress and strain was a common experience. It followed, therefore, that no more injudicious course could be taken with the patient than that of rendering him "nervous" about the condition of his "heart" or so hedging him about with restrictions as to suggest that little lay between him and dissolution. Rest of body and mind, regulation of food, and cardiac tonics were indicated, whether hæmic, neural, and muscular, or these combined, and later graduated exercises by baths, gymnastics, or walking. But as time advanced and hypertrophy increased, giving way later to dilatation, and they had a large ineffective organ pulsating in the thorax and crowding neighbouring organs directly and indirectly, the question arose whether anything else could be done to render cardiac action more easy and to relieve the patient for a longer or shorter period. They were all aware of the baneful influence upon the circulation of removeable accumulations within the chest, such as air, serum, pus, or blood, accumulations that is, which by their pressure "crowded" the heart and hampered it in its easy and free movement. They might legitimately, therefore, surmise *a priori*, that when the central organ took the initiative in congesting and encroaching upon the lungs, relief of intrathoracic pressure by costal resection might also in some cases be beneficial. Dr. Morison thought that he would be justified on the first available opportunity in putting these views to the test of experience.—Dr. David Ross showed an improved Chest-piece for Binaural Stethoscopes which he had been using for several months.—The following office-bearers were elected for the session 1907-08:—President: Dr. W. Langdon Brown. Honorary secretary: Dr. David Ross. Honorary treasurer and curator: Dr. B. G. Morison. Council: Dr. J. R. T. Conner, Dr. Leslie Durno, Mr. G. Angus Hunt, Mr. W. Campbell McDonnell, and Dr. J. S. Risien Russell.

LARYNGOLOGICAL SOCIETY OF LONDON.—A meeting of this society was held on April 5th, the President, Dr. J. B. Ball, being in the chair.—Dr. St. Clair Thomson exhibited a man, aged 29 years, who had been shown at the previous meeting on account of a Malignant Shown at the previous meeting on account of a Malignant Endo-laryngeal Growth. Since then an operation had been performed for its removal, and a section of the growth was exhibited. 'As some of the members were unable to satisfy themselves that the growth was of a malignant nature it was decided to refer it to the Morbid Growths Committee for a further opinion. The interest of the case rested in the early age of the patient.—Dr. Thomson also exhibited a woman, aged 50 years, with Prolapse of the Ventricle of

diagnosis, the patient being a lady who had lived in China for 11 years and during the past year had developed a pigmented eruption upon the neck, arms, legs, and abdomen. There was no history of any preceding eruption; there were no subjective symptoms except moderate itching; the mucous membranes were not involved. No swellings or alterations in the nerve trunks could be detected. It was considered impossible to come to any decision as to the character of the eruption in its present condition.—Dr. Colcott Fox showed a case of *Lupus Vulgaris* dating from an attack of measles at the age of two years. The patient was a boy now aged ten years and he had recently developed a follicular eruption, which the exhibitor was inclined to regard as a miliary tuberculide of the nature of *lichen scrofulosorum*.—Dr. H. G. Adamson showed a child with a Reddened Shiny Soft Congenital Tumour of the size of half-a-crown. In some respects this resembled a lymphangioma, but the consensus of opinion favoured the diagnosis of soft mole.

MEDICO-LEGAL SOCIETY.—A meeting of this society was held on April 16th and was devoted to toxicology. Mr. Walter Schröder presided.—Professor H. Harvey Littlejohn described three cases of Fatal Poisoning by Strychnine, including the recent "Cumnock shortbread poisoning case." It appeared that in each of the cases consciousness was present during the convulsions. Professor Littlejohn also described a Fatal Case of Poisoning by Potassium Bichromate. The necropsy was performed six hours after death while the blood was unreduced and contained met-hæmoglobin which gave the skin the characteristic hue.—Dr. W. H. Willcox, Dr. W. Scott Tebb, and Dr. S. B. Atkinson discussed these cases.—Dr. Scott Tebb described a Fatal Case of Poisoning by Oxalic Acid, and gave a short historical account of the use of this poison.—The next meeting will be held on June 18th, when Dr. O. H. Wise will give a paper on *Facts and Opinions in Medical Practice*, and Dr. Willcox will describe a Case of Gunshot Wounds (illustrated by specimens).

MANCHESTER CLINICAL SOCIETY.—A meeting of this society was held on April 16th. Dr. J. F. Le Page, the President, being in the chair.—Dr. G. H. Lancashire read a paper on Tuberculous Skin Affections. The common bacillary types of disease were described, especial attention being paid to lupus vulgaris and its treatment. It was pointed out that there was still considerable scope for caustic methods of treatment in lupus, amongst the best caustics for this purpose being a saturated solution of zinc chloride, of pyrogallol or of potassium permanganate. The last Dr. Lancashire employed in the form of powder, which was packed into holes made in the nodules by means of a wooden skewer, the powder being afterwards moistened. In this way several nodules could be treated at a sitting, a local anæsthetic being preferably used. Diseases of the so called *toxi-tuberculides* type were also described and a case shown which was held to be a *papulo-necrotic toxi-tuberculide*.

Reviews and Notices of Books.

The Prophylaxis and Treatment of Internal Diseases. By F. FORCHHEIMER, M.D., Professor of Theory and Practice of Medicine and Clinical Medicine, Medical College of Ohio, Department of Medicine of the University of Cincinnati; Physician to the Good Samaritan Hospital London: Sidney Appleton. 1906. Pp. 652. Price 21s. net.

THIS work is designed for the use of practitioners and of advanced students of medicine and the author has carried out his task with success, embodying in his remarks the results of 30 years' experience in hospital and private practice. In dealing with the treatment of the various diseases he mentions those methods first which he himself has found most serviceable, subsequently describing other measures recommended by accepted authorities. The directions suggested for prophylaxis are such as can be readily carried out in private practice and the most modern therapeutic systems of all kinds are fully considered. Thus much space is devoted to hydrotherapy, gymnastics, exercises, and diet, always with a view to their adaptation to

private patients. When the requirements are so expensive or elaborate as to necessitate a special establishment certain resorts are suggested where such can be satisfactorily obtained. Surgical methods are referred to mainly from the point of view of the physician and unless there is some special object for so doing no reference is made to the technique of operations. We have perused the work with much pleasure and have found Dr. Forchheimer's recommendations and suggestions fully trustworthy and up to date.

In describing the treatment of typhoid fever hydrotherapeutic measures naturally take first place, for in America the employment of baths is more common than in this country. Brand's method, a combination of baths and massage, has yielded excellent results. The advantages claimed are that the course of the disease is shortened, the nervous symptoms are controlled, the circulation is improved, the condition of the mucous membranes is changed for the better, and lastly, the mortality is diminished. We are not aware that a full trial has been given to this method in England, but it would be interesting to ascertain whether the results of such a course would compare favourably with the means now generally adopted. The remarks on the prophylaxis of tuberculosis are well worthy of attention. Dr. Forchheimer lays stress on the importance of popular teaching in the fight against the disease. This tuition must be given lucidly, for, as he says (and we are entirely in accord with him), much harm may be done to the tuberculous individual if the chances of prevention of the disease are not stated clearly and forcibly. We quote the author's own words: "Fear is best controlled by knowledge, and our knowledge of tuberculosis is positive as to its prevention. The danger in the popular conception is exaggeration, which in this case makes a leper of the patient, destroys his utility, and frequently deprives a whole family of its natural supporter." This argument has been strongly urged against the proposals for compulsory notification, and in our opinion is a weighty one and needs careful consideration before mandatory legal measures are generally adopted.

The author's views on the treatment of pleurisy with effusion differ somewhat from those which are usually held by English physicians. He maintains that when effusion is the result of primary pleurisy paracentesis is always indicated. "It matters not," he says, "whether the level of the fluid reaches the top of the first or the fifth rib; whether the patient is in immediate danger or not." He refers to the fact that the older clinicians laid down the rule that there should be no operation when fever was present. Dr. Forchheimer then remarks: "When there is great dyspnoea or the fluid collects very rapidly so that there is danger of suffocation, the operation should be done at once; otherwise the subsidence of inflammatory symptoms may be waited for; but even here I aspirate early, whether the effusion is large or small, my own experience having taught me that aspiration when a patient has fever is not followed by a re-accumulation of fluid. On the contrary, more frequently aspiration acts in the same way as would the opening of an abscess; the fluid disappears and the fever with it." These remarks are interesting and worthy of full consideration. There is a tendency on the part of some practitioners to postpone operation as long as possible in the hope that the fluid will be reabsorbed. The author deprecates this course of action. He considers that the early removal of fluid prevents the formation of adhesions. The importance of attempting to prevent adhesions is obvious, as they play an important rôle in the production of bronchiectasis, chronic pneumonia, and deformities of the chest. If early withdrawal of the fluid will tend to prevent such sequelæ then certainly it should be adopted. Dr. Forchheimer also very rightly lays stress on the necessity of regulating the

ksome. Salt might be to a considerable extent replaced by sugar in the dietary. The modern treatment of high tension by nitrites and nitrates had been recommended by the great Bacon in the time of Elizabeth, as the only remedies he recommended for prolongation of life were nitre and blood-letting. The nitre he employed probably contained a quantity of nitrates and blood-letting as a remedy which had fallen too much into disuse and in cases of high tension might be employed again with advantage. He showed von Basch's instrument as modified by Potain for estimating blood pressure and also combination of this instrument with Riva Rocci's armlet. —Dr. Herbert S. French reminded the society that cases of very high blood pressure occurred even amongst those who were at the same time vegetarians, non-smokers, and life-long abstainers. —Dr. Oliver, in reply, agreed that rest in bed would diminish the high blood pressure even in the worst cases, but this was owing to a diminished call upon the cardiac end of the circulation. In those who were obliged to work the ventricle factor could not be diminished and such cases seldom reacted to depressor drugs so long as they remained up and about. He thoroughly approved of the revival of venesection for such cases.

GLASGOW MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on April 6th, Dr. J. Walker Lowrie, Vice-President, being in the chair. —Dr. Albert A. Gray showed the Temporal Bones of a patient who suffered from serous catarrh of the middle ear. Both tympana were all of gelatinous pearly-grey material. The membranes were adducted but not perforated. The mucous membrane of the tympanum and antrum was softened and friable. The stapes was moveable. The exudation filled up the middle ear, antrum and mastoid cells, and attic. This case explained the frequent absence on the membrane of any line of demarcation between the lower part of the tympanum which was filled with fluid and the upper air-filled part. —Dr. H. Wright Thomson showed cases illustrating Skin-grafting in Ectropion, Symblepharon, and Rodent Ulcer. The skin flap was mapped out and rapidly removed along with the subcutaneous fat, which was afterwards removed with curved scissors. The cases were greatly benefited by the operation. —Dr. G. T. Beatson reported a case of Translucido Asphyxia. The patient, who was a man, aged 24 years, was crushed by a pit cage, the compression being antero-posterior and the shoulders being crushed downwards and forwards. On admission to hospital two hours after the accident there was intense congestion of the head and neck, almost petechial in character but not affected by pressure. There was also considerable oedema around the eyes and mouth. There was some proptosis indicating hæmorrhage into the orbit. There was no fracture. In three days the congestion and discoloration had faded and by the eighth day were only present in the forehead and now yielded to pressure. There was discoloration around the eyes and nose as in an ecchymosis. This also soon disappeared. —Professor John Glaister referred to the importance of such cases from a medico-legal aspect and referred to some cases which had occurred by crushing in a crowd. —Dr. George H. Edington, Dr. Somerville, and Dr. A. Young referred to other cases. —Dr. Young gave a lantern demonstration illustrating a Modification of the Wolfe-Krause Method of Skin-grafting. The whole skin and fat were rapidly removed and placed in sterile saline solution. The wound was then stitched up. The raw surface was then prepared for the grafts, which were then made ready by removing the fat and cutting them into suitable pieces. A layer of protective gauze was then applied and a moist boric or saline dressing was put on. The moist dressing was changed daily but the gauze was not removed for several days.

BRITISH BALNEOLOGICAL AND CLIMATOLOGICAL SOCIETY.—A meeting of this society was held at 20, Hanover-square, on April 10th, Dr. Frederic Bagshawe (St. Leonards-on-Sea) being in the chair. —The adjourned discussion on "The Present Position of the Treatment of Tuberculosis in Marine Climates," which was introduced by Dr. William Ewart at Hastings on March 16th, was resumed by Dr. Alfred F. Street (Westgate-on-Sea). He said that the weight of evidence was on the side of those who contend that pulmonary catarrh is essentially microbic in origin and that it always owns a factor other than mere cold. The humidity of marine climates was usually a tolerable humidity, for humidity must always be considered in relation with temperature, the really important point being

the amount of moisture which could still be absorbed before saturation was reached. The climate of the north coast of the Isle of Thanet had long been recognised for its favourable influence in cases of tuberculosis, especially those amenable to surgery, but its precise factors were not yet discovered. Cases of locally originated tuberculosis were rare there. Hæmoptysis might be relatively more frequent at the seaside than inland and there was need for abundant open-air shelter. As maintained by the opener of the discussion, the more extensive and more systematic use of our marine climates was strongly indicated. —Dr. E. Solly (Harrogate) alluded to the beneficial influence of variety of scene to all who were obliged to seek health under the necessarily restricted conditions of a sanatorium life, and in this respect a "sea view" offered advantages which no inland station could afford. —Dr. S. D. Clippingdale expressed the view that a case of phthisis in any stage of the disease did better in a bracing climate than in a relaxing one. —Dr. Leonard L. B. Williams said that it was necessary to draw distinctions between various kinds of marine climates. It depended upon the type of tuberculous person which of these climates should be recommended. —Dr. Ewart, in reply, explained that the bacilli could not be directly influenced by such slight oscillations of temperature or such moderate variations of climate as occurred within the temperate zones. But to their host these influences made all the difference. He entirely agreed with Dr. Street and other speakers as to the unequalled value of the bracing climate of Thanet, but it was liable to be too "strong" for the more advanced cases of phthisis, although invaluable in the early stage and in surgical tuberculosis.

INCORPORATED SOCIETY OF MEDICAL OFFICERS OF HEALTH.—A meeting of this society was held on April 12th, Dr. D. S. Davies, the President, being in the chair. —Dr. J. Wright Mason read a paper upon the Inspection of Food at our Ports. He said that there was no universal method for examining imported cargoes of food-stuffs, only two authorities, those of London and Manchester, having special powers of examination vested in them. Under these powers the examination is conducted immediately upon arrival and before the food-stuffs are deposited or exposed for sale. Elsewhere food-stuffs are only examined after being landed and deposited for sale. This anomalous position would be remedied by the Public Health (Regulations as to Food) Bill now before Parliament. Dr. Mason said that, in his opinion, an inspection before being landed or before leaving the docks would not only be beneficial from a public health point of view, but would also be some guarantee to the public generally that they are being more fully protected. The power to inspect a ship's cargo consisting of food-stuffs before or when being landed would enable an inspector to satisfy himself as to whether the cargo had been stowed in a proper manner so as to avoid the cargo being damaged, or whether injury had arisen owing to the proximity of other and objectionable cargo. With regard to tinned foods Dr. Mason was strongly of opinion that they should be required to bear the name and address of the manufacturer and the date when packed. He urged the importance of providing suitable warehouse accommodation for the purpose of examining and sorting cargoes of food-stuffs of a doubtful and perishable character. —In the course of the discussion which followed the President emphasised the importance of uniformity in methods of examination at the various ports of entry, for importers would divert traffic from those ports where stringent measures were enforced. —Dr. E. W. Hope pointed out that stricter examination at the ports would not absolve inland sanitary authorities from the obligations at present placed upon them.

DERMATOLOGICAL SOCIETY OF LONDON.—A meeting of this society was held on April 10th, Dr. T. Colcott Fox being in the chair. —Dr. Wilfrid S. Fox showed a case for diagnosis. The patient was a man, aged 42 years, who had had syphilis 14 years previously. He had lived much in South America, where the disease for which he was shown had appeared about six years ago. He was now extensively covered with a small papulo-pustular eruption which was particularly marked on the back of the thighs. These lesions recalled the papulo-pustules of acne scrofulosa and a section from one such lesion showed a losorum and a section from one such lesion showed a cellular infiltration about the blood-vessels with numerous plasma cells, an appearance which was suggestive of tuberculosis. The general opinion was in favour of a diagnosis of tuberculides. —Dr. E. G. Graham Little showed a case for

etiological agency to these conditions and in this respect the authors rightly assume a conservative attitude. Nevertheless, in the present relations of civilised life, physiological functions are carried out in a highly artificial environment and are liable to react adversely upon a debilitated organism. The authors have wisely interpolated a chapter upon the theory of menstruation and have described briefly the little which is known or conjectured about the effects of the process upon the blood and upon the general system. The facts elicited tend to support the view that suppression of the normal function causes an auto-intoxication which may induce ocular complications under suitable conditions. We have seen a case of thrombosis of the central vein of the retina in a girl whose sole constitutional defect was a temporary suppression of menses and the association of iridocyclitis with disorders of the sexual apparatus in women is well established. It may be hoped that in the future further researches will be carried out upon the condition of the blood during menstruation and other physiological and pathological states of the sexual organs. There is little doubt that profound changes exist, having important bearings not only upon ophthalmology but upon other branches of medicine.

LIBRARY TABLE.

The Royal London Ophthalmic Hospital Reports. Edited by WILLIAM LANG, F.R.C.S. Eng. Vol. XVII. Part 1. London: J. and A. Churchill.—The present number commences a new volume of these old-established reports. It fully sustains the high reputation which they have gained in the past. Mr. E. Nettleship continues his extremely interesting and valuable researches on the influence of heredity in ocular disease. His paper deals with so-called retinitis pigmentosa and allied diseases. He has collected some astonishing pedigrees from his own experience and from the writings of others. His graphic method of representing his results, familiarised to readers of the reports by his previous papers on cataract, shows the salient points of each pedigree at a glance. Mr. Nettleship rivals Sherlock Holmes in his skill and perseverance in tracking down individual suspects. In his case of retinitis pigmentosa seven generations, including 200 persons, have been traced, with the discovery of 38 members affected by the disease. The paper is one of importance not only to ophthalmologists, who are not likely to overlook any work of this distinguished clinician, but also to those interested in the problems of heredity, for the evidence derived from disease may well be found to play a decisive rôle in the controversy of the rival theories. The paper will be concluded in the ensuing number of the reports. Mr. J. B. Lawford, walking in the footsteps of his sometime colleague at St. Thomas's Hospital, records examples of hereditary primary glaucoma. In one pedigree four generations have been traced, three showing members, five in all, affected with the disease. Mr. George Coats writes upon the Pathology of Macular Holes and an Unusual Form of Cyst of the Iris. Both papers are illustrated by excellent microphotographs. The first is an exhaustive discussion of a condition which can only rarely be elucidated by microscopical examination. The wealth of material which the Royal London Ophthalmic Hospital supplies has provided the curator of the museum with four cases for his valuable investigation. Mr. E. E. Henderson and Miss Janet E. Lane-Clayton report a Study of the Ciliary Epithelium after Puncture of the Anterior Chamber. The paper deals with an experimental and histological investigation of certain points in connexion with the secretion of the intra-ocular lymph, a subject which the first author has previously studied with Professor Starling. Mr. W. Albert Hancock has furnished a thoughtful communication on Head Nodding and Nystagmus. His observations on

spasmus nutans are of great interest; his criticisms of prevalent theories of the disease are chiefly destructive. He rightly distinguishes these cases rigidly from those of congenital head-nodding which are also associated with nystagmus but which do not undergo spontaneous resolution. Dr. T. Harrison Butler discourses upon the Clinical Features, Bacteriology, and Treatment of Acute Ophthalmia in the East, giving an analysis of 5700 cases observed whilst occupying the post of assistant surgeon to the British Ophthalmic Hospital at Jerusalem. We welcome this contribution to the literature of ophthalmology from this noble charity. The author's pathological results are somewhat revolutionary from the standpoint of western investigations and we shall await the confirmation of his experience of the incidence of the various organisms of acute ophthalmia with interest.

Lateral Curvature of the Spine and Pelvic Derivations. By RICHARD BARWELL, F.R.C.S. Eng., Consulting Surgeon, Charing Cross Hospital; Surgeon, Cripples' Home. Sixth edition. London: Baillière, Tindall, and Cox. 1905. Pp. 103. Price 3s. net.—We have reviewed with approbation early issues of this work, but this sixth edition deserves especial notice, as for it the book has been entirely rewritten. The chief idea embodied in this edition is that the starting-point of the greater number of cases of lateral curvature of the spine is an obliquity of the pelvis and as a corollary it must necessarily follow that treatment to be effective should be directed, not merely to the secondarily affected spinal column but to the primary pelvic obliquity. In the chapter on Certain Prevalent Methods of Treatment the author discusses the therapeutic means usually employed and he shows that they may fail to achieve what is desired. The greater part of the book is devoted to treatment, and the methods advocated are described sufficiently fully to enable an estimate to be formed of their value. We are in accord with very much of what the author maintains and we think that he has given a very lucid account in this little book of the great importance of pelvic deviations in the production of lateral curvature. The treatise must prove helpful to anyone anxious to understand fully the production and treatment of these deformities.

The World's Classics. Volume LXI. *The Autocrat of the Breakfast Table.* By OLIVER WENDELL HOLMES. Oxford University Press: Henry Frowde. Pp. 271. Price 1s.—In our issue of April 6th, in reviewing certain volumes of "The World's Classics," we said that the sight of "The Professor at the Breakfast Table" and "The Poet at the Breakfast Table" made us hope that a future number of "The World's Classics" would be "The Autocrat of the Breakfast Table." We now learn that this particular volume was issued quite early in the series and Mr. Frowde has kindly sent us a copy. There is no need at this time to praise these delightful essays, to say nothing of such possessions for ever as "The Chambered Nautilus," "The Living Temple," "The Wonderful One-Hoss Shay," and "Contentment," poems which shine like jewels in the setting of the prose.

Photographic Atlas of the Diseases of the Skin. In four volumes. A series of 96 Plates, comprising nearly 200 illustrations with descriptive text and a treatise on Cutaneous Therapeutics. By GEORGE HENRY FOX, A.M., M.D., Professor of Dermatology, College of Physicians and Surgeons, New York; Consulting Dermatologist to the Department of Health, New York City; Physician to the New York Skin and Cancer Hospital, &c. Vol. IV. London and Philadelphia. Pp. 62 and 24 plates. Price 25s. net each volume.—This is the concluding volume of the present issue of Dr. G. H. Fox's atlas. He is one of the most energetic dermatologists in bringing out atlases of diseases of the skin and they have all been excellent. The use of photography in the portrayal of skin diseases has its limitations, but these

after-treatment of cases of pleurisy with effusion as a large proportion of them have been proved to be tuberculous in origin.

The part of the work dealing with the treatment of diseases of the nervous system (especially the section on epilepsy) will also be found instructive, while the whole book teems with information and practical hints most suggestive for actual practice. The form in which the work is written also adds to its value as rendering it suitable for reference and we can therefore recommend it as a desirable addition to the library for constant use.

Rome as a Winter Resort. By A. G. WELSFORD, M.D. Cantab. With Introduction by G. SANDISON BROOK, M.D. Edin. Rome: 1907.

SINCE Sir James Clark, some 90 years ago, wrote a special treatise on the subject "Rome as a Winter Resort" has evoked from physicians of various nationalities a series of vindications on the lines of that well-known book—all of them coming to the same conclusion epigrammatically driven home by Dr. Gsell-Fels a generation ago: "*Als Winteraufenthalt könnte Rom besser verwertet werden, wenn es nicht Rom wäre.*" It is not the climate itself, still less, in these days, the defective sanitation, that makes the Eternal City dangerous to the visitor, but the imprudences of which the said visitor is guilty in his enthusiastic exploration of catacombs, ruins ancient and mediæval, museums, galleries, and other claimants on his time, his attention, and (let us add) on his physical endurance. If in these days of "raw haste" and "condensed hurry" the visitor could be persuaded to do his sight-seeing leisurely the risks he incurs by a sojourn in Rome would be less than in almost any other European capital, but with such temptations addressed to the ecstatic tripper as "Rome in Ten Days" or even "A Month in Rome" it is to be feared that "candidates" for one or another of the ailments to which all flesh is heir will never be wanting even in "this so-called twentieth century." Gregory XVI. in the audiences he gave to the visitor from abroad used to ask how long he had been in Rome, and when told that he had been "all the winter" would smile and say, "*A rivederla.*" or "*Au revoir,*" or "*Auf Wiedersehen.*" But when the answer was "for a few weeks" he would sigh and say, "*Addio,*" or "*Adieu,*" or "*Lebe wohl,*" with a significance which appealed not more to the artist or the historian than to the medical man.

Dr. Welsford makes an effective contribution to the literature of what may be called "Roman apologetics," and in the little volume before us subjects to a thorough and cogent review the claims of the city, in point of climate and of health conditions, to be a permanent place of abode or a temporary resort for the invalid. With the advantage of "coming last" in the long line of similar treatises he is able to strengthen his "apologia" with the latest statistics as well as with the most approved and accepted findings of research—meteorological, sanitary, bacteriological, and clinical—and adduces evidence enough to warrant Dr. Sandison Brook in his hope that it will "dissipate once for all the prejudices and misapprehensions which still deter the traveller from a pilgrimage to the Eternal City." The articles on Temperature, on Relative Humidity, on Barometric Pressure, on Rainfall, and on the Prevailing Winds are compiled from the most authoritative sources, private as well as official, the only section on which we could have wished more detailed handling being that of the water-supply, in supplement to the special report of Professor Cannizzaro and his colleagues dealt with in THE LANCET some 22 years ago.¹ That

supply still remains unrivalled for purity and abundance but since the recent multiplication of dwelling-houses the courtyard fountains from which it "shook its loosened silver in the sun" has been too often replaced by the domestic reservoir or cistern where it is liable to be contaminated with the effluvia or sordes of the overcrowded tenement. Significant in this connexion is the fact, put on record by the Roman physicians of the last generation, that typhoid fever was absolutely unknown in the Rome of those days, and that the clinical student who wished to familiarise himself with its etiology, its pathology, and its response to treatment had to go to other centres of population. *Au reste*, we would draw attention to the article on Malaria as eminently reassuring in its presentation of the risks incurred from that disease. "There are no malarial foci within the walls," concludes Dr. Welsford sentimentally. As to that other "hereditary spaurachio" (scarecrow), the sirocco, which has been well defined as "heat without sun, wind without air, and rain without freshness," Dr. Welsford gives it the *coup de grâce*, adding: "It blows only 15 days in the year." A parting word as to the illustrations. These are taken from the photographs of Mr. Anderson, on whom has worthily fallen the mantle of Robert Macpherson, who, some "sixty years since," was the first to apply the photographer's art to the reproduction and presentation of the many archaeological and artistic treasures of Rome.

Ueber Augenkrankungen sexuellen Ursprunges bei Frauen. (*Diseases of the Eye of Sexual Origin in Women.*) By Dr. EMIL BERGER, Foreign Corresponding Member of the Royal Belgian and Royal Spanish Academies of Medicine; and Dr. ROBERT LOEWY, Chief Assistant of the University Gynaecological Clinic in Paris. German revised edition, translated by Dr. BEATRICE ROSSBACH, Physician for Diseases of Women in Madison, U.S.A. Wiesbaden: J. F. Bergmann. 1906. Pp. 171. Price 4 marks.

SUBJECTS on the border-line of two branches of medicine are liable to receive scant attention, falling, as it were, between two stools. Such monographs as the present therefore serve a useful purpose. It is written by an ophthalmologist and a gynaecologist, a combination which prevents many errors which might result from a one-sided view of the question. In it are collected most of the cases recorded in literature of disease of the eye caused by, or associated with, diseases peculiar to women. As a bibliographical work alone it is of great utility to the ophthalmologist, and in less degree to the gynaecologist, but its usefulness is enhanced by the well-balanced comments and hypotheses of the authors.

After a short historical introduction the book deals in sequence with diseases of the eye reported as occurring during normal menstruation, at puberty, with dysmenorrhœa and suppression of menses, at the climacteric, associated with diseases of the genital organs, during pregnancy, parturition, lying-in, and lactation. Septic affections of the eye secondary to diseases of the sexual organs and abnormalities of vision following uterine hæmorrhage are fully discussed. A chapter is devoted to the deleterious effects of parturition, spontaneous or artificially aided, upon the eyes of the infant and to the infectious purulent inflammations of the conjunctiva in the newly born.

A review of the literature, such as is presented here, brings into prominence the frequency with which both simple and obscure affections of the eye are attributed to physiological and pathological conditions of the female sexual organs, often upon quite insufficient grounds. Menstruation and pregnancy, with its concomitants, parturition and lactation, are physiological processes, whilst dysmenorrhœa and suppression of menses are common complaints, rarely attended with disorders of the ocular apparatus. There is need for the exercise of great care in attributing an

¹ THE LANCET, Dec. 20th, 1884.

between lesion of Broca's area and this affection; and Mr. J. C. Pretorius writes on Colour Vision, propounding the hypothesis that the different colours of the spectrum stimulate sections of individual "cones" lying at different depths in the retina, corresponding with the focal lengths of these colours as they pass through the lens.

ERRATUM.—In our notice of Professor Ainsworth Davis's biography of the late Professor Huxley we inadvertently described the volume as belonging to the series of "English Men of Letters"; it belongs to the series of "English Men of Science" published by Messrs. J. M. Dent and Co.

Reports and Analytical Records

FROM

THE LANCET LABORATORY.

(1) ALAXA; AND (2) QUININE ACETYL-SALICYLATE.

MESSRS. BURROUGHS, WELLCOME, AND CO., SNOW HILL BUILDINGS, LONDON, E.C.)

1. ALAXA is a pleasant liqueur containing cascara sagrada in combination with certain stomachic and carminative principles. It is free from gripping or irritating action and is suggested, in particular, as a useful tonic laxative during pregnancy. Each fluid drachm contains the equivalent of 24 minims of the liquid official extract of cascara sagrada. 2. The advantage of quinine acetyl-salicylate over ordinary quinine salicylate is that in the former case the acetyl-salicylic acid set free in the stomach passes on unchanged, causing no gastric disturbance. In the case of quinine salicylate, salicylic acid, on the other hand, is liberated, which is a gastric irritant. Aceto-salicylic acid dissolves in the alkaline contents of the intestine. Quinine acetyl-salicylate is of value in the treatment of febrile conditions.

SPARKLING CLOS DES CORDELIERS.

(MESSRS. G. DE MEYNOT AND CO., ST. EMILION; AGENTS, EDWARD ARCHER AND CO., MALVERN.)

We can quite accept the statement in regard to this excellent wine that the same careful attention is paid to it as in the production of the more renowned sparkling wine, champagne. It possesses excellent bouquet and flavour and, in short, exhibits many of those attractive qualities which distinguish a good champagne. The wine is grown at St. Emilion, a district which is famous for producing a wine of claret style but which, generally speaking, possesses greater body than claret, thus approaching the character of burgundy in this respect. This fact no doubt contributes to the success of St. Emilion as a sparkling wine, for it exhibits the rich quality of a sound champagne. The following analysis reveals its composition, which shows no appreciable difference from that of champagne itself: alcohol, by weight 10·85 per cent., by volume 13·43 per cent., equal to proof spirit 23·54 per cent.; extractives, 4·17 per cent.; mineral matter, 0·12 per cent.; sugar, 3·00 per cent.; glycerine, 0·348 per cent.; tannin, 0·114 per cent.; volatile acidity reckoned as acetic acid, 0·13 per cent.; and fixed acidity reckoned as tartaric acid, 0·57 per cent. The wine is described as "first growth St. Emilion, carte Noire extra dry vintage, 1895," and the price is 48s. per dozen.

LIQUID SOMATOSE.

(THE BAYN CO., LIMITED, 19, ST. DENNIS'S HILL, LONDON, E.C.)

Previously we have referred to somatose in the form of powder. For those who prefer this powerful food in a fluid form liquid somatose, both sweetened and unweetened, has been introduced. According to our analysis the preparation contains nearly a fourth its weight of solid matter and

approximately 70 per cent. of this consists of the soluble proteose. It is, of course, a powerful nutrient.

MOSTELLE GRAPE JUICE.

(THE GRAPE JUICE COMPANY, LIMITED, 4, FURNIVAL-STREET, LONDON, E.C.)

'We have not examined better specimens of grape juice than those recently submitted to us by the above firm. They possess the luscious flavour of the grape, whilst exhibiting also a pleasant acidulous taste. They are perfectly free from antiseptics, the method of preservation being simply that of pasteurisation. The red colour of the red juice proved to be identical with the colouring matter of the black grape. The composition of the red juice proved to be as follows: extractives, 26·65 per cent.; grape sugar, 24·08 per cent.; mineral matter, 0·25 per cent.; and acidity, reckoned as tartaric acid, 0·68 per cent. The white juice gave the following results: extractives, 26·97 per cent.; grape sugar, 25·64 per cent.; mineral matter, 0·27 per cent.; and acidity, reckoned as tartaric acid, 0·50 per cent. Both specimens, which were made from Spanish grapes, contained the merest trace of alcohol, which, of course, it is hardly possible to avoid; the amount was certainly less than two-fifths per cent. by volume. Grape juice when diluted with aerated water affords a refreshing and wholesome beverage. It may also be used when a grape diet is prescribed and particularly when there is a difficulty in obtaining the fresh fruit.

STERILISED LUBRICANT.

(MESSRS. S. MAW, SON, AND SONS, 7 TO 12, ALDERGATE-STREET, LONDON, E.C.)

The lubricant is semi-transparent and is contained in a collapsible tube provided with a mouth which is concave in shape, a device which is intended to prevent soiling the fingers with the contents and which also secures uniform lubrication. The lubricant is simple in composition and free from irritants. It is designed for use with catheters, instruments, or for lubricating the hands. The tube contains sufficient lubricant for one day's use when the catheter is employed three times during that period.

EFFERVESCENT PIPERAZINE (MIDY).

(L. MIDY, PARIS. AGENTS: THE ANGLO-AMERICAN PHARMACEUTICAL COMPANY, LIMITED, FRITH-BROAD, CROYDON, LONDON, S.E.)

According to Dr. Dujardin Beaumetz, piperazine Midy is a commendable preparation and extremely well tolerated. It certainly affords a pleasant way of exhibiting this remarkable uric acid solvent. The base has also been used in gout and as a remedy for renal colic. Piperazine Midy is a granular and effervescent powder which produces a brisk effervescence when placed in water. The measured dose of the powder contains four grains of pure piperazine. The effervescing liquid is practically tasteless. Since piperazine is deliquescent the fact that this granular powder keeps dry may be attributed to pharmaceutical skill.

(1) IODALBIN; (2) COMPRESSED TABLETS PHENOLPHTHALEIN COMPOUND; AND (3) NUTRITIVE LIQUID PEPTONE.

(MESSRS. PARKE, DAVIS, AND CO., 111, QUEEN VICTORIA STREET, LONDON, E.C.)

1. Iodalbin is suggested as an efficient substitute for the ordinary alkaline iodides, while it is said to avoid the gastric irritation of those salts and yet to secure their therapeutic effects. It occurs in the form of a rust coloured powder which is insoluble in water, acids, or alcohol but readily so in alkaline solutions. It passes through the stomach unaltered to be gradually absorbed in the intestine. The iodine to the extent of 21·5 per cent. is combined with a protein substance. 2. The phenolphthalein compound in the form of a compressed tablet contains one grain of phenolphthalein, 15th grain strychnine sulphate, and 15th grain of extract of belladonna leaves. Phenolphthalein is now well known as a laxative, this effect as a rule being obtained without pain. The value of the addition of

illustrations are practically as good as photographs can be. The treatise on treatment is likely to prove useful; it is moderate in tone. Sometimes the author appears to us to be unnecessarily pessimistic in regard to the efficacy of treatment.

The World Machine: First Phase, the Cosmic Mechanism. By CARL SNYDER. London: Longmans, Green, and Co. Pp. 488. Price 9s. net.—The author of this work might well quail before his subject, which is no less than the epitomising in this volume and two others to follow of the whole plan, physical, cosmical, and social, of the universe. We will first express a hope that the ending of his labours will lead him to a less lugubrious conclusion than is contained in the five lines of undiluted Nietzsche that front this volume, but in spite of this the stupendous issues involved are set forth, so far as they have been revealed by science, in a way that may be understood of the people. A medical journal cannot fully review a survey of astronomical history, but we may say that the work is informed with a thorough knowledge of how from Ptolemaic darkness and through Copernican dawn at length the Newtonian day grew bright, a transition that finds an adequate biological parallel in the sun of Listerian methods that so much later in the world's history dissipated the murky gloom of the surgery of laudable pus. It is an interesting reflection on the rapid transitions of modern science that within so few decades of the apparent shattering of the walls of the doctrine of spontaneous generation by Pasteur's trumpet-blast, such a book as this can more than hint at the possibility of their being again set up.

The Psychic Riddle. By ISAAC K. FUNK, D.D., LL.D. London and New York: Funk and Wagnalls Co. 1907. Pp. 243. Price \$1 net.—Another plea from America for the dispassionate consideration of the claims of spiritualism. Dr. Funk's present solution of his riddle is thus summed up: "That intelligences who are foreign to us, that is, who reside beyond our five senses, can and do communicate through the physical sense organs with some of those who are living in the flesh." However, he denies the complete confession of spiritualism, which, says he, includes this further article: "That these intelligences can and do identify themselves as those who once lived in the flesh." To the acceptance of this doctrine, we are told, there remain some very formidable difficulties. Exactly, and a perusal of the "phenomena" set down in these pages appreciably advances its disproof, as especially witness the tricksy "spirit" of Theodore Parker, which, manifesting itself to the learned doctor through different mediums, always had a different tale to tell! We must credit the author, however, with a recognition of frequent fraud in "spiritualism," although the tone of his work indicates a strong sympathy with many of its conclusions, and we need hardly state that the opinions of Lodge and Lombroso are called in evidence for the thesis. The book ends with a string of aphoristic dark sayings, of which this may serve for type, "Those who do not love death do not know it."

A Treatise on Materia Medica and Therapeutics. By RAKHALDAS GHOSH, L.M.S. Cal. Edited by O. P. LUKIS, M.D. Lond., F.R.O.S. Eng., Lieutenant-Colonel I.M.S. Third edition. Calcutta: Hilton and Co. Pp. 737. Price Rs. 5, or 7s. 6d.—The appearance of a further edition of this excellent manual justifies the good opinion expressed in THE LANCET when it was first issued in complete form in 1904. The late author had an extensive knowledge of his subject and the task of editing the work has been very ably carried out by Lieutenant-Colonel Lukis. We note that our former suggestion as to the value of volatile ethers in alcoholic stimulants has been included in this edition, and in the next we hope to see a repetition of the warning against prescribing alkaloids with bromides and iodides given under the

heading of the latter drugs as well as under the general list of incompatibles, which omission we previously suggested should be corrected. The work as a whole is excellently arranged, and the sections on pharmacology and therapeutics will be useful to practitioner as well as student.

Lessons on Massage. By MARGARET D. PALMER. Third edition. Illustrated. London: Baillière, Tindall, and Cox. Pp. xvi.-272. Price 7s. 6d. net.—We congratulate Miss Palmer on the appearance of a third edition of her work which bids fair to become a standard text-book on massage. Of course no text-book can replace practical work, and he or she who would become an adept in effleurage, tapotement, and the rest must rely on practice above all things, for the best book can only be an adjunct of limited use. It is in the chapters on bones and muscles that the student will find his chief help. The authoress could not have hit upon a happier motto for her work than the Hippocratic aphorism, which she quotes: "Rubbing can bind a joint that is too loose and loosen a joint that is too rigid." In this edition the sections on certain deformities have been revised and are now thoroughly trustworthy.

JOURNALS AND MAGAZINES.

The Edinburgh Medical Journal.—In an article in the April number of this journal Dr. F. W. N. Haultain makes a clinical and anatomical study of 30 cases of cervical fibroids removed by abdominal hysterectomy. The symptoms caused by these growths are more severe than those resulting from corporeal fibroids and the results of operation are less favourable. Dr. R. T. Williamson writes on Progressive Muscular Atrophy and Amyotrophic Lateral Sclerosis, which he considers to be distinct affections, and Dr. Dawson F. D. Turner recommends examination of the respective electrical conductivities of the blood and urine as a test of the functional efficiency of the kidneys. Dr. F. Parkes Weber records a case of polyneuritis in which great gastro-intestinal dilatation occurred, probably due to implication of the pneumogastric nerves.

The Bristol Medico-Chirurgical Journal.—The March number of this magazine opens with an interesting article by Dr. P. H. Pye-Smith on Prognosis, containing many shrewd reflections and aphorisms relating to a variety of diseases. Dr. D. S. Davies and Dr. I. Walker Hall write on Cerebro-spinal Fever (Meningitis), basing their remarks on cases admitted to the Bristol Royal Infirmary since 1901, and Dr. P. Watson Williams writes on the Treatment of Deflections and Deviations of the Nasal Septum. Dr. A. Lewin Sheppard discusses Acquired Angioma of the Liver, with notes of a case; and two cases of Ruptured Intestine ending in recovery and one of Splenomegaly Cirrhosis in a child, aged seven years (a final note), are recorded respectively by Mr. Harold F. Mole and by Dr. Edward Cecil Williams.

The Dublin Journal of Medical Science.—The two numbers of this journal now before us—those for March and April—are above the average in the variety and interest of their original articles. The former contains a series of papers on Gastric Ulcer, which are chiefly of importance as illustrating the views of their writers—Dr. James Little, Sir Charles Ball, Dr. J. A. Lindsay, and Mr. Arthur B. Mitchell—as to the advisability of surgical interference. The first-named writer records that in recent years several patients have consulted him for stomachs which gave great trouble and that among the principal signs he was obliged to mention a "scar five inches long" in the linea alba. The April number opens with a first instalment of an exhaustive account of "Our Debt to Ireland in the Study of the Circulation," with a voluminous bibliography, by Dr. G. A. Gibson. Dr. Frank C. Parser discusses current theories of Aphasia, alluding especially to Marie's doubts as to the reality of the connexion

wide end of a glass tube between four and five inches long (here only represented in part). To use the apparatus water is poured into the boiler at the opening marked "Wasser" from a measure holding 100 cubic centimetres, and the lamp is lighted underneath. For use in the other compartment marked "Medicin" the medicinal substance selected is introduced at the proper opening with a small spoon holding a suitable quantity. The vapour of this, heated by the steam of the boiling water, issues in a fine jet from the vertical nozzle, and the jet of steam directed across it drives clouds of strongly medicated vapour up the glass tube, mixed with hot air and steam. Dr. Saenger recommends that the inhalations should last from 10 to 15 minutes and that they should be repeated from four to six times daily. These inhalations are contra-indicated when there is a tendency to hæmoptysis. A considerable variety of substances may be inhaled in this way, including oil of turpentine, oil of eucalyptus, menthol, thymol, balsam of Peru, camphor, creasote, carbolic acid, and guaiacol. Administered in this way they have been found useful in various forms of bronchial catarrh, whether chronic, acute, or associated with pulmonary tuberculosis; also in cold in the head, sore-throat, and whooping-cough. The apparatus is portable and can be easily made ready for use at any time in a few minutes.

It may be obtained from the principal instrument makers and dealers in druggists' sundries.

THE ELECTRIC MOTOR HAIR-BRUSH.

[WE are assured of the economical and mechanical advantages of this machine, which is illustrated below, but our interest in the invention lies chiefly in its sanitary aspects. In an annotation which was published in THE LANCET of March 16th, 1907, p. 753, it was remarked that while the sterilisation of combs, brushes, razors, and the hands of the operator may avail much, the rotary machine-brush scattering dust, scurf, and so forth from the dry scalp remained an unwholesome instrument. It is difficult to suggest a practical method by which this can be overcome, yet we

think the electric motor hair-brush deserves a word of praise in this connexion, inasmuch as its use is calculated to reduce the process of brushing hair by machinery to a hygienic level. To begin with, the motor is part and parcel of the brush itself, so that the current may be drawn from any point by means of a socket attachment which is identical in principle and method with the ordinary incandescent electric lamp. Thus the shafting and belting of the old method is done away with and the operator is perfectly independent of a similar operation which may be going on at the same time. All that is required are a lamp and "lead." Further, the brushing can be conducted without trouble in a separate compartment. As will be seen, however, from the illustration the brush is provided with a baffle or screen which prevents the scurf from being distributed broadcast as is the case with the ordinary brush. Moreover, the brush can readily be detached from the motor for cleaning purposes, the frame being constructed of aluminium. There are no crevices in which dust can lodge. If the customer desires he can keep his own brush for his own exclusive use. These are sanitary advantages which must be obvious to everybody. The brush is under complete control owing to the ease with which the switch can be turned on or off by moving it with the thumb. The motor can be adapted to any circuit, and is supplied for the usual range of voltage from 100 to 250 volts and either for direct or alternating current. The cost of current for driving the brush in an ordinary shop is stated to be about 2d. per week for an outlay of £12. Altogether this electric rotary brush is a clever device, and one to which we may heartily accord our approval, since it gives the hair-dresser further opportunity of placing his operations on a really sanitary basis. The electric motor hair-brush is the property of the Light Electric Motor Co., Limited, of Seven

LONDON AND COUNTIES MEDICAL PROTECTION SOCIETY.

THE annual general meeting of the London and Counties Medical Protection Society was held at 31, Craven-street, Strand, London, W.C., on April 18th, Dr. G. A. HERON being in the chair.

The annual report of the Council for 1906 formed a volume of over 100 pages and showed the large amount of work carried on by the society. Under the heading of defamation of character a number of instances were given of the way in which assistance was afforded to members of the society; one offender in regard to whom clear evidence was forthcoming was written to and he was finally made to publish in all the local newspapers a withdrawal and an apology as drafted by the society. The treatment of fractures usually affords work for medical defence societies and in the following case given in the report of the council the member interested certainly had no reason to complain of the result. This gentleman had attended a "mother's help" for fracture of both bones of the forearm. Union did not take place satisfactorily and ultimately an operation was performed, the result of which was not all that could be wished. The member complained that reports were getting about to the effect that he had set the bones badly. Accordingly the society wrote letters to the girl's mistress and to another lady accusing them of slandering the medical man. Both ladies at once put the matter in the hands of their solicitors. Ultimately one lady gave a written apology which was accepted and the mistress's explanation that her words had been quite misunderstood was also accepted. The member expressed sincere thanks for the assistance of the society in clearing up an awkward situation which threatened to have a disagreeable effect on his professional position. In another case two partners, members of the society, complained that payment of their account had been refused with threat of an action for malpraxis. The alleged malpraxis was in regard to the treatment of a fractured elbow-joint. The union of the fracture had resulted in some limitation of the movements of the arm. The patient had been sent to the London Hospital and efforts had been made to improve the movements of the arm. The father of the patient was written to and told that he perhaps did not recognise that fractures involving the elbow-joint, no matter how carefully and skilfully treated, quite commonly cause some crippling of the movements of the arm. The medical men had treated the case with skill and care and he ought not to blame them because the result was not all that could be wished for. Hope was expressed that the medical men would not be compelled to take proceedings and the complainant was told that the society would defend its members if any charge of negligence or want of skill were made against them. Shortly afterwards the partners wrote to the society saying that the complainant had paid his account and was satisfied. The usual number of cases of the following nature were satisfactorily dealt with by the society. A member complained of annoyance by letters from a patient whom he had attended for uterine troubles. She appeared to imagine that he had acted improperly and was written to and warned. She called at the society's offices and was told she had no grounds of complaint against the medical man and must not molest him in any way; she agreed to do as she was told.

Dr. HERON, in moving the adoption of the report, which was duly seconded and carried unanimously, stated that he was justified in saying that financially the society was the soundest of its kind in the country.

The meeting terminated after the transaction of the usual formal business, in the course of which the members expressed their cordial appreciation of the work done for the society by the general secretary, Dr. Hugh Woods.

THE SOCIETY OF ARTS.—Sir Edward C. Buck, late Secretary to the Government of India, Revenue and Agricultural Department, will read a paper before the Indian Section of the Society of Arts on Thursday afternoon, May 2nd, on the Applicability to India of Italian Methods of Utilising Silt. The subject has medical, as well as agricultural and geographical interests, as it is claimed that the Italian work has proved a great preventive of malaria. The chair will be taken at 4.30 o'clock.

strychnine and belladonna is obvious. 3. The nutritive liquid peptone contains soluble protein prepared by means of bromelin, the hydrolytic agent of pine-apple juice. The chief advantage of peptone obtained in this way is that it is free from bitter taste. The preparation also shows diastasic power. According to our analysis the preparation contains 18.65 per cent. of solid matters, but the total nitrogen amounted to only 0.31 per cent. By adding to this preparation a few minims of beechwood creasote and of guaiacol it is made suitable for those suffering from gastric disorders, flatulence, &c., while it improves nutrition in sufferers from respiratory diseases and diminishes cough.

TURKISH CIGARETTES (SACKVILLE BRAND).

(ALEXANDER BOGUSLAVSKY, 3, SACKVILLE-STREET, PICCADILLY, LONDON, W.)

These cigarettes have been sent to us on the ground that they are made from carefully selected tobacco leaf and that accordingly they can be smoked without giving rise to irritation. The smoke from them is certainly as free from irritating effects or pungency as we imagine tobacco smoke can be, while the aroma is delicate and pleasing. Moreover, the tobacco is free from dust which we regard as an important point.

CYDER.

(WILLIAM GAYMER AND SON, ATTLEBOROUGH, NORFOLK.)

That Norfolk can produce excellent cyder is plain from a careful consideration of the qualities of the specimens sent to us by the above firm. The samples ranged according to description from "extra dry" to "sweet," intermediate samples being denominated as "old natural," "natural," "medium dry," "very dry," and so on. We give the analyses of a few selected specimens, the results serving to show the chief variations in the composition of differently designated cyders. The "old natural," for example, gave the following results: alcohol by weight, 7.93 per cent.; extractives, 5.00 per cent.; mineral matter, 0.33 per cent.; sugar, 3.22 per cent.; malic acid, 0.28 per cent.; and acetic acid, 0.34 per cent. Sparkling Pometta (resembling a hock in character but less alcoholic) gave the following results: alcohol by weight, 7.27 per cent.; extractives, 4.35 per cent.; mineral matter, 0.25 per cent.; sugar, 2.77 per cent.; malic acid, 0.23 per cent.; and acetic acid, 0.24 per cent. Oldfield perry gave the following results: alcohol by weight, 6.57 per cent.; extractives, 5.70 per cent.; mineral matter, 0.32 per cent.; sugar, 2.43 per cent.; malic acid, 0.21 per cent.; and acetic acid, 0.21 per cent. (as will be seen it contains less sugar than the previous specimens and less alcohol). In no instance did we find the volatile acid, recorded as acetic acid, to exceed 0.34 per cent., which is evidence of the sound condition of the cyders.

New Inventions.

AN EYE PROTECTOR FOR USE AFTER CATARACT EXTRACTION, WOUND OF EYEBALL, &c.

NUMEROUS eye protectors for use after cataract extraction have been suggested by Fuchs, Snellen, and others. For some years I have used a wire protector made for me by Down Bros. Lately I have adopted modified motor goggles and have found them extremely useful. They consist of a detachable calico front piece, to the ends of which a piece of broad tape or elastic is attached. Two round metal rims one and three-quarters inches in diameter and half an inch high are inserted. The sides of these are pierced by numerous holes, for ventilation. The rims are covered with tinted glass. After the cataract operation a thick oblong piece of absorbent cotton wool or Gamgee tissue is placed over each eye (3 inches by 2½ inches) and the protector is tied round the head, the rims resting on the cotton-wool pads. After from two to five days the pad is removed from the eye which has

not been operated on, and in from five to eight days from other eye. The advantages of this protector are: (1) the eye which has been operated on is completely and securely covered and it is impossible to damage the eye by a blow any kind; (2) the cotton-wool pad can be removed much sooner from either eye as the protector excludes bright light and cold air; (3) no strapping or bandage is required; (4) it is very cool and comfortable; (5) it is quite aseptic, as it

rims can easily be detached and all parts readily sterilised (6) when the pads are removed no dark glasses are necessary as long as the patient remains indoors; and (7) it is very cheap. The protector is also very useful in the treatment of any eye diseases, operations, and accidents when the eye has to be covered or protected from bright light.

The protector has been made for me by Allen & Hanbury, Limited, of Wigmore-street, London, W.

ADOLPH BRONNER, M.D.,
Senior Surgeon to the Bradford Eye and Ear Hospital
Laryngologist to the Bradford Royal Infirmary.

Bradford.

A NEW MEDICINAL EVAPORATOR.

THE apparatus, of which a vertical section is shown in the accompanying illustration, has been devised by Dr. A. Saenger of Magdeburg for the treatment of bronchial and pulmonary diseases by the inhalation of medicated vapour. It consists principally of a circular copper boiler about three inches in diameter and two inches high, supported on three

feet of a sufficient length to let a small spirit lamp stand underneath it. On the upper surface there are two inlets, one of which, indicated by an arrow and the German word "Wasser," communicates with the general cavity of the interior, while the other one, also indicated by an arrow, communicates with a separate internal chamber marked "Medicin." Each of these cavities has also an outlet in the form of a fine nozzle. These two nozzles meet at a right angle as shown,

seem to involve the prohibition of the use of many other substances which are largely used in industry and which have caused a much larger number of industrial accidents. Moreover, one effect of such prohibition would be to throw out of employment a large number of workers. It seems to us that in this case the policy of the Home Office of gradual regulation and control rather than sudden and actual prohibition is a wise one from an administrative standpoint, and it may be that the remarkable progress in factory legislation and administration which has marked Dr. WHITELEGGE'S term of office in the Factory Department is due largely to this spirit of compromise, a spirit which has been always associated with steady advance. But whatever may be the outcome of further investigations which are being made relative to the match industry, it is obvious that the workmen themselves cannot be regarded as by any means free from blame. The dangers which they incur must be obvious to them, as also must the facilities which are afforded for obviating such dangers, and to absolve the workman from all responsibility is surely a policy fraught with disastrous consequences to his moral fibre.

The Turkish Lazarets.

WE begin in another column a series of articles upon the Turkish lazarets which we hope will be found interesting to our readers. We are certain that they give information which has never been before available upon the important work for the preservation of the health of Europe undertaken by the Constantinople Board of Health, by the British delegate of which board they are written. The word "lazaret," as applied to some of the institutions dealt with in the articles, is in many ways an unfortunate one. To most uninstructed minds it conjures up visions of the poorest of poor-houses, sheltering ragged beggars with loathsome sores, like these of the Lazarus of the parable, or even lepers in all degrees of deformity. To such it comes as a surprise to learn that a modern "lazaret" is nothing of the kind, but in many instances a vast and costly establishment where healthy people are kept under observation for a short period, in order that any case of cholera or plague developing among them may be at once isolated and dealt with. In 99 instances out of 100 no such disease develops and the pilgrims (for whom most, but not all, of the lazarets are provided) leave the institutions with little more to complain of than the delay. In the meantime they have had the advantage of a rest, of undergoing at least one good douche-bath, and of having their clothes and effects thoroughly disinfected in a modern steam stove.

For many lazarets positions of great natural beauty or attractiveness have been chosen. Those of Camaran and Abu-Saad, for instance, occupy coral islands in the Red Sea—sites which, though they can scarcely lay claim to any beauty, have a very marked and interesting character of their own. The lazaret of Tor is built in an oasis on the strip of desert at the foot of the Siwaic range—a spot of unsurpassed attractiveness. That of Beirut occupies a promontory jutting out into the Mediterranean, near the foot of the

Lebanon, and the views all round are truly splendid. Were all the other qualities of these establishments on the same high level of perfection as the natural sites they occupy all the world would wish to live in lazarets. Unfortunately, however, most of them are very far from perfect. Some sink to very low depths of imperfection and are the subject of constant complaint from those who have to undergo quarantine in them. Others require much to be done to them before they can be said to come up to any ideal standard of perfection. To this last category belong most of the lazarets described in the articles. During the winter 1905-06 the Constantinople Board of Health despatched a commission, consisting of three of its members, to inspect some of the principal lazarets under the board's management. The commission was composed of the British and Greek delegates and one of the Turkish members of the board. While the primary object of the commission's work was to inspect the large lazaret of Camaran, near the southern end of the Red Sea, advantage was also taken of the opportunity to visit and report upon several other of the board's sanitary institutions—notably the lazarets of Abu-Saad, near to Jeddah, and of Beirut, and the new disinfecting stations of Jaffa and Rhodes. The British delegate being a member of the commission, had thus the occasion to examine thoroughly several institutions for the prevention of the spread of epidemic diseases, some of which are of international importance, not only on account of the part they play in protecting Europe from those diseases, but also from the prominence assigned to them in the proceedings of successive international sanitary conferences.

The only information hitherto available in regard to these institutions has been contained in reports to the Constantinople Board of Health from the officials in charge of them. Such reports are but too often of a fragmentary character, and, indeed, a comprehensive and detailed account of the actual state of any of these lazarets or sanitary stations did not, until the return of the inspection commission, exist. Further, of most of them there were either no detailed plans or plans of a very elementary (and, it must be added of some, inexact) character, while in the case of none of them had photography been systematically employed to bring home to those responsible for their management the nature and actual condition of the institutions they had to deal with. The difficulty experienced in the management and upkeep of these large and distant establishments can in the circumstances be easily imagined; and it is undeniable both that errors have been committed in the past from the lack of such information and that the institutions themselves have suffered to some extent in consequence. The reports, now printed, of the inspection commission should go far to fill up these regrettable gaps in the knowledge of those concerned. These reports (in French) have been presented to the board and to the governments interested, and it may be hoped that the detailed recommendations they contain for the thorough repair and completion of the institutions in question will ere long be put into practice. The reports are profusely illustrated with charts, plans, and diagrams, and with a series of photographs taken by the British delegate, many of which will be reproduced in his articles in our pages.

THE LANCET.

LONDON: SATURDAY, APRIL 27, 1907.

The Workman's Share in the Promotion of Industrial Poisoning.

IN all legislative reforms and in all our efforts to reduce the prevalence of preventable diseases the main obstacles which have first to be overcome are the greed of the employer and the ignorance of the workman and, unfortunately, both forces are sometimes found marshalled on the same side. Generally, however, it is the element of avarice which prevents the employer from introducing, except under legal pressure, the necessary reforms, while it is the forces of ignorance, prejudice, and suspicion which preclude the workers from reaping the full harvest of such reforms when at last they have been inscribed on the pages of the Factory Acts. An example of what must be regarded as a most culpable negligence on the part of the workman has recently been brought to light in a joint report¹ made to Mr. HERBERT GLADSTONE by Mr. H. H. S. CUNYNGHAME, Assistant Under-Secretary of State for the Home Department, and Dr. B. A. WHITELEGGE, H.M. Chief Inspector of Factories, upon a fatal case of phosphorus poisoning in a match factory at Gloucester. The fact that the soluble white or yellow phosphorus is still employed in the manufacture of lucifer matches will doubtless come somewhat as a surprise to many who have not followed events in the match industry, and it is probably a common impression that although yellow phosphorus matches are introduced into this country from abroad public opinion has prohibited their manufacture at home. Such, however, is not the case and, if we may read between the lines of the report which we are now noticing, it is more likely that the yellow phosphorus match industry will be rendered practically harmless than that the manufacture of such matches will be actually prohibited; and this notwithstanding the circumstance that in the factory at Gloucester in which the fatal case of poisoning already referred to took place both "safety" and "strike anywhere" matches are made without the use of white phosphorus.

Considerable importance has clearly been attached by the Home Office to this fatal case of phosphorus poisoning at Gloucester, but the facts elicited by the important officials who investigated it would not seem to warrant the conclusion that the factory in question was wholly, if at all, responsible for the disaster. The victim had been formerly employed for about 12 years in a match factory in Ireland and at a time when but few precautions

were taken. Some two years after commencing work at Gloucester a trivial accident resulted in the fracture of the man's thigh and, as it failed to "set," amputation was resorted to. The fact of this fracture suggested to Mr. CUNYNGHAME and Dr. WHITELEGGE that it may have been induced by the peculiar brittleness of bones which is a recognised condition amongst those who have been exposed to the fumes of phosphorus for many years, and this view appears to have received support from the fact that the arrangements in the Gloucester factory were not such as to lead to the belief that the patient was really exposed to phosphorus fumes. Be this as it may, the duties assigned to the workman now in question were, having regard to the fracture and subsequent amputation of his leg, unfortunate, although the employers were probably acting under the belief that they were doing a kindly action. There were but few tasks which a cripple such as this could perform, and he was seated at the revolving table upon which the matches are lowered to receive their dip of phosphorus, his duty being to keep the table properly covered with its sticky paste of warm glue, white phosphorus, and chlorate of potash which he poured thereon by hand out of a ladle. Both the table and the pot containing the mixture were covered with a hood, through a window in which the workman watched the movements and requirements of the dipping table. This hood appeared to be working effectually and smoke generated near it was at once carried away. But, unfortunately, the crippled workman had contracted an inveterate habit of chewing tobacco, and as his infirmity precluded him from leaving his seat periodically to wash his hands it is not improbable that he conveyed phosphorus to his mouth together with the tobacco. He developed "phossy-jaw" and died. This view of the origin of the tragedy receives some support from the circumstance that at one of the dipping machines the hands of those employed were found smeared with phosphorus paste in dangerous amounts, while at both the machines in use the hands of the person removing the frames containing the dipped matches were found in practically a similar state. As will have been seen the process of dipping is not yet wholly automatic, although the firm here in question is doing its best to devise an automatic machine the introduction of which would, it is believed, cost thousands of pounds. For the most part the factory seems to be well conducted, although on one occasion the proper use of the mouth wash was neglected and on another there had been resistance to the wearing of overalls. It was not thought, however, that there was ground for prosecution, as the firm has voluntarily had a monthly dental examination of their workmen in place of the quarterly examination required by the special rules. An undertaking has now been given to introduce sundry reforms, such, for instance, as providing gloves for the workers at the dipping tables, the prohibition of tobacco chewing, and the repeated inspection of the workers' hands during work.

This incident and the report thereon raise several interesting points, such, for example, as the prohibition of the use of white phosphorus and the introduction of completely automatic machinery. The prohibition of white phosphorus would relieve the Home Office of much trouble, but, as the experts point out, such total prohibition would logically

¹ Report to the Secretary of State for the Home Department by H. H. S. Cunynghame, Esq., C.B., Assistant Under-Secretary of State, and B. A. Whitelegge, Esq., C.B., M.D., H.M. Chief Inspector of Factories, on the Match Factory of Messrs. Moreland and Sons, Gloucester, with special reference to a recent fatal case of phosphorus necrosis. Wyman and Sons, Limited, Fetter-lane, E.C. 1907. Price 1d.

consequent upon an open window or door. If the teacher draws down the blind or closes the offending ingress for air the practical application of the hygienic teaching is lost, because the school building is not adapted to the purpose it is supposed to fulfil, or because the class is too large by reason of the school being overcrowded.

Hospitals were never intended, we presume, to be used as educational establishments so far as the patient is concerned, but there is evidence to show that these institutions play no unimportant part in engendering in the suffering poor who are treated in them hygienic habits which are afterwards reflected in the home life. This useful result is due in a great measure to the fact that our hospitals, owing to a lavish out-pouring of charitable funds, are becoming day by day more structurally suited to their purposes. In like manner the school ought to have a powerful effect on the home life of the child, but we fear that this is not so in many cases. Architects have had this subject under their attention for years, and it is not a reproach upon the experts that the school buildings are so often faulty. But it is a reproach upon the nation and one that we trust will gradually be removed. The general provision of elementary schools according to modern scientific requirements would mean the expenditure of a larger sum of money than the nation would be prepared to pay, but the necessity for national education having been admitted it must now be recognised as false economy to attempt to educate the child on a system which does not lead to the best results.

The Prevention of Tuberculosis.

PROPOSALS for the introduction of legislative measures to assist in the prevention of tuberculosis are being constantly brought to the notice of the public sanitary authorities. The most prominent of these are concerned with the question of food-supply and the introduction of compulsory or voluntary notification. We have recently received two communications on the subject which are of considerable interest and importance. One is a report from Dr. WILLIAM COLLINGRIDGE, the medical officer of health of the City of London, relative to the second interim report of the Royal Commission appointed to inquire into the relations of human and animal tuberculosis. The second communication is from the secretary of the Edinburgh Local Government Board and is entitled "Administrative Control of Pulmonary Phthisis." Here we may once more express our regret that the term "pulmonary phthisis" has been employed. The expression "pulmonary tuberculosis" is from a pathological point of view more correct and convenient and we trust the word "phthisis" will be allowed to become obsolete, since it is both wrong and unscientific. Dr. COLLINGRIDGE gives a good summary of the second interim report of the Royal Commission on Tuberculosis and points out that the conclusions arrived at are of vital importance as affecting the food-supply of the country and the line of action which should be adopted by sanitary authorities in dealing therewith. The recommendations emanating from the first Royal Commission in 1896 were somewhat discountenanced by the announcement made by Professor B. Kossel at the Congress

on Tuberculosis held in London in 1901, that while bovine tuberculosis was easily communicable from animal to animal human tuberculosis was not capable of being so conveyed, and that he was unable to accept the possibility of infection of man from animals. Naturally enough, as Dr. COLLINGRIDGE points out, this pronouncement was largely accepted by the trade and from that date it practically became an article of faith with those dealing in cattle that tuberculosis could not be conveyed to man from animals. The two interim reports of the second Royal Commission, dated respectively 1904 and 1907, go far to prove that the effects of the bacillus of bovine and human tuberculosis are one and the same. This contention is supported by the evidence accumulating from all parts of the world as to the identity of human and bovine tuberculosis.

The Commissioners were able to give a positive answer to the question as to whether the human body could be infected by bovine tuberculosis. They were further of opinion that a very considerable amount of disease and loss of life, especially among the young, must be attributed to the consumption of cow's milk containing tubercle bacilli. Dr. COLLINGRIDGE is of opinion, and we are in agreement with him, that the second interim report, to which we have referred, calls for no change in the present position of meat inspection, since the degree of danger incurred by the consumption of the flesh of tuberculous animals is probably not great. The recommendations of the first Royal Commission remain as the standard by which meat in this country is to be judged. The standard may, or may not, be altered in the future but in the meantime the correct course is to accept it absolutely, and the various sanitary authorities should take precautions to ensure that the circulars of the Local Government Board are strictly complied with. With regard to milk-supply, the danger to health and life has been proved to be a real and ever-present one and more stringent measures are necessary to prevent the use of tuberculous milk. The question naturally arises as to the nature of these measures. Dr. COLLINGRIDGE urges in the first place that the making of regulations under the Dairies, Cowsheds, and Milkshops Order should be compulsory throughout the country, and some modifications bringing them up to date should be made, and we maintain that speedy and stringent legislation in this direction is called for. Careful supervision of farms, cattle, and milk utensils would be necessary but until orders in Council are made mandatory but little good can result from such precautions. The Contagious Diseases Act, 1878, gave power to the Privy Council (now transferred to the Local Government Board) to make an order under which local authorities were empowered (*inter alia*) to make regulations for the inspection of cattle in dairies, for securing the cleanliness of milk stores and of milk utensils, and also for regulating the lighting, ventilation, cleansing, drainage, and water-supply of dairies and cowsheds. If these regulations were made compulsory on every sanitary authority much would be done to lessen the danger that arises from tuberculous cows.

The document emanating from the secretary of the Edinburgh Local Government Board is also an interesting one. The term, "pulmonary phthisis," is also adopted here, although the synonym, "tuberculosis of the lungs,"

School Hygiene.

THE Second International Congress on School Hygiene which is to be held in London, under the presidency of Sir LAUDER BRUNTON, during August Bank Holiday week will certainly be attended by a profoundly interested public. And of these we hope that many will recognise that the time has come for us to include in our national scheme of primary education due attention to the mental and physical condition of the children. It is almost inevitable that a great reform like the Education Act of 1870 should bring trouble in its train, for it may be taken as an axiom that the law of progress is a law of sacrifice; but our children, in whom our hopes for the race are vested, should not be the victims. Hitherto the nation has not fully reaped the results expected when we first aided education financially and subsequently made it compulsory. It is true that the general intellectual standard has been raised, and it is probable that many of the statements to the effect that the elevation has been at the expense of physical fitness have been made on insufficient grounds, but no one disputes that school hygiene has still to be developed as a national movement. With the increased knowledge of 35 years the time has, we hope, arrived when our primary education will be carried out under conditions which will result in a larger measure of utility to the nation, and the injustice which pure ignorance has caused some of our children to suffer will be removed. The forthcoming Congress, composed, as it promises to be, of men and women of experience in educational questions in every civilised country in the world, should be the starting point for a new order of things. Quite apart from sentiment, quite apart from the interests of the children, the mental, moral, and physical education of those who will be the fathers and mothers of future generations is of the most vital importance to the existence of a nation. A race, to maintain its position among the peoples of the world, must of necessity be composed of healthy men and women; their physique will assist their mental capacity, but both must be good to be able to cope with the advance of knowledge which has characterised the past century, and which promises to be still more rapid in the years immediately before us.

That we have been slowly awakening to a sense of our responsibilities in the matter of education and its bearings on national physique is shown by reference to recent Royal Commissions, Parliamentary inquiries, and Departmental Committees which have dealt with questions of physical degeneration. Numerous societies have also begun to discuss the hygiene of childhood and allied subjects, a section of educational science has been started at the meetings of the British Association, and the furtherance of the teaching of hygiene and temperance in elementary schools has been officially approved of by the British Medical Association. A conference on "The Teaching of Hygiene and Temperance in the Universities and Schools of the British Empire" was held on Tuesday afternoon last at the examination hall of the Conjoint Board of the Royal College of Physicians of London and the Royal College of Surgeons of England. This conference was convened by a composite committee of the hygiene and temperance committee of the medical profession and of the

health committee of the British Medical Association, and the attendance was strengthened by the inclusion among the speakers of prominent colonial citizens present in this country in connexion with the Imperial Conference. The sessions were presided over by Lord STRATHCONA, the veteran High Commissioner for Canada, and Sir JOHN GORST, recently Minister of Education, whose attention to the conditions by which the health and vigour of the children of the nation can be promoted by the State have recently been incorporated in a popular volume. Interesting papers were read by Mr. J. L. HUGHES, chief inspector of schools in Toronto, and Sir VICTOR HORSLEY, while practical addresses were delivered by the Hon. ALFRED DEAKIN, the Prime Minister of the Commonwealth of Australia, Mr. FRANK GOULD, Sir J. A. COOKBURN, M.D., a late Minister of Education in Australia, Sir PHILIP SYDNEY JONES, M.D., the well known Australian physician, Mr. ALFRED MOSLEY, and others whose personal interest in all questions of education, hygiene, and temperance are well known to our readers. This Conference, held at the time when these very subjects are engaging the attention of Parliament and the public, ought to have an important bearing upon national thought, and will help to insure that the International Congress on School Hygiene will commence its labours in the autumn of this year in possession of a varied audience and with wide sympathies in its work already aroused.

To return to this Congress, its programme, showing the many distinguished authorities who will take part in its discussions, justifies the hope that the hygiene of education will be dealt with thoroughly in all its bearings. There is one matter which has not hitherto received the practical attention from medical men which it rightly demands—namely, the construction of school buildings in the light of the requirements demanded by modern scientific knowledge. In suburban areas, where houses are springing up rapidly and where the population soon outgrows the educational accommodation, the necessary overcrowding of the children in the school may form an evil of the greatest consequence to the population from the health point of view. The influence of the school on the spread of infectious diseases is well known, and, as Sir LAUDER BRUNTON has pointed out, in pleading for the pressing need for medical inspection, that the infection of one child may result in an epidemic of scarlet fever or diphtheria which may spread over a district. This obvious fact must appeal to all as a reason for considering very carefully the sanitary construction of school buildings. Again, it is manifestly difficult to teach children lessons of hygiene which they will respect, while the building where they spend a great part of their time affords an object lesson in opposition to the subject taught. Everyone knows that an object itself creates a lasting impression on the mind of children, while a verbal description may leave them comparatively unmoved, and it is useless to attempt to impress upon a child the importance of fresh air or the beneficial effect of sunlight while the construction of the school may be such as to make both a positive hindrance to teaching. While one child is suggesting that he cannot see the blackboard because the sun is shining directly in his eyes another may be complaining of carache

consequent upon an open window or door. If the teacher draws down the blind or closes the offending ingress for air the practical application of the hygienic teaching is lost, because the school building is not adapted to the purpose it is supposed to fulfil, or because the class is too large by reason of the school being overcrowded.

Hospitals were never intended, we presume, to be used as educational establishments so far as the patient is concerned, but there is evidence to show that these institutions play no unimportant part in engendering in the suffering poor who are treated in them hygienic habits which are afterwards reflected in the home life. This useful result is due in a great measure to the fact that our hospitals, owing to a lavish out-pouring of charitable funds, are becoming day by day more structurally suited to their purposes. In like manner the school ought to have a powerful effect on the home life of the child, but we fear that this is not so in many cases. Architects have had this subject under their attention for years, and it is not a reproach upon the experts that the school buildings are so often faulty. But it is a reproach upon the nation and one that we trust will gradually be removed. The general provision of elementary schools according to modern scientific requirements would mean the expenditure of a larger sum of money than the nation would be prepared to pay, but the necessity for national education having been admitted it must now be recognised as false economy to attempt to educate the child on a system which does not lead to the best results.

The Prevention of Tuberculosis.

PROPOSALS for the introduction of legislative measures to assist in the prevention of tuberculosis are being constantly brought to the notice of the public sanitary authorities. The most prominent of these are concerned with the question of food-supply and the introduction of compulsory or voluntary notification. We have recently received two communications on the subject which are of considerable interest and importance. One is a report from Dr. WILLIAM COLLINGRIDGE, the medical officer of health of the City of London, relative to the second interim report of the Royal Commission appointed to inquire into the relations of human and animal tuberculosis. The second communication is from the secretary of the Edinburgh Local Government Board and is entitled "Administrative Control of Pulmonary Phthisis." Here we may once more express our regret that the term "pulmonary phthisis" has been employed. The expression "pulmonary tuberculosis" is from a pathological point of view more correct and convenient and we trust the word "phthisis" will be allowed to become obsolete, since it is both wrong and unscientific. Dr. COLLINGRIDGE gives a good summary of the second interim report of the Royal Commission on Tuberculosis and points out that the conclusions arrived at are of vital importance as affecting the food-supply of the country and the line of action which should be adopted by sanitary authorities in dealing therewith. The recommendations emanating from somewhat different sources are as follows:

1896 were
made by
a Congress

on Tuberculosis held in London in 1901, that while bovine tuberculosis was easily communicable from animal to animal human tuberculosis was not capable of being so conveyed, and that he was unable to accept the possibility of infection of man from animals. Naturally enough, as Dr. COLLINGRIDGE points out, this pronouncement was largely accepted by the trade and from that date it practically became an article of faith with those dealing in cattle that tuberculosis could not be conveyed to man from animals. The two interim reports of the second Royal Commission, dated respectively 1904 and 1907, go far to prove that the effects of the bacillus of bovine and human tuberculosis are one and the same. This contention is supported by the evidence accumulating from all parts of the world as to the identity of human and bovine tuberculosis.

The Commissioners were able to give a positive answer to the question as to whether the human body could be infected by bovine tuberculosis. They were further of opinion that a very considerable amount of disease and loss of life, especially among the young, must be attributed to the consumption of cow's milk containing tubercle bacilli. Dr. COLLINGRIDGE is of opinion, and we are in agreement with him, that the second interim report, to which we have referred, calls for no change in the present position of meat inspection, since the degree of danger incurred by the consumption of the flesh of tuberculous animals is probably not great. The recommendations of the first Royal Commission remain as the standard by which meat in this country is to be judged. The standard may, or may not, be altered in the future but in the meantime the correct course is to accept it absolutely, and the various sanitary authorities should take precautions to ensure that the circulars of the Local Government Board are strictly complied with. With regard to milk-supply, the danger to health and life has been proved to be a real and ever-present one and more stringent measures are necessary to prevent the use of tuberculous milk. The question naturally arises as to the nature of these measures. Dr. COLLINGRIDGE urges in the first place that the making of regulations under the Dairies, Cowsheds, and Milkshops Order should be compulsory throughout the country, and some modifications bringing them up to date should be made, and we maintain that speedy and stringent legislation in this direction is called for. Careful supervision of farms, cattle, and milk utensils would be necessary but until orders in Council are made mandatory but little good can result from such precautions. The Contagious Diseases Act, 1878, gave power to the Privy Council (now transferred to the Local Government Board) to make an order under which local authorities were empowered (*inter alia*) to make regulations for the inspection of cattle in dairies, for securing the cleanliness of milk stores and of milk utensils, and also for regulating the lighting, ventilation, cleansing, drainage, and water-supply of dairies and cowsheds. If these regulations were made compulsory on every sanitary authority much would be done to lessen the danger that arises from tuberculous cows.

The document emanating from the secretary of the Edinburgh Local Government Board is also an interesting one. The term, "pulmonary phthisis," is also adopted here, although the synonym, "tuberculosis of the lungs,"

is placed within brackets. Some useful remarks are made on disinfection of rooms which have been occupied by tuberculous patients, and on the isolation and treatment of those suffering from the disease. It is urged that local authorities, instead of attempting by themselves to provide the trained medical skill and scientific laboratories necessary for effective management, should either utilise existing sanatoriums or combine with other authorities for a properly equipped sanatorium. With this suggestion we are entirely in accord, for as we remarked in a leading article in THE LANCET of April 6th of this year, we have already suffered great disappointment from idle prophecies and ill-considered theories. We would further remind our readers that the ultimate results of open-air treatment have yet to be manifested. Especially in regard to the benefits to be derived by the working classes from "sanatorium treatment" sufficient time has not yet elapsed to enable a definite pronouncement to be made as to the percentage of cases in which absolutely permanent arrest ensues. We are afraid that the hopes freely expressed by the advocates of sanatoriums for the working classes may not be fully justified, and local authorities may well hesitate before expending public funds upon the erection of new buildings. In this report some interesting remarks will be found on "Dispensaries for Pulmonary Phthisis," and we cordially endorse the suggestions that are made. The work of such a dispensary should include (a) the medical examination of patients, either at the dispensary or in their own homes; (b) inquiry by a medical man or a competent nurse into the history of the illness, the home conditions, the economic condition of the family, the occupation, and so on; (c) arrangements for providing medical treatment and nursing of patients who can be treated at home without risk of infection; and (d) dispensing of medicines and disinfectants. These and many other provisions, especially personal and printed instructions to the patients and their friends as to the modes of preventing the spread of the disease, would do more, we believe, to lessen the incidence of the disease than any other measures. The mortality from pulmonary tuberculosis has fortunately greatly decreased of recent years, and we strongly deprecate undue haste in the adoption of stringent regulations which are of doubtful utility and may endanger the social life of the community.

Annotations.

"No quid nimis."

THE MEDICAL PROFESSION AND THE RECENT BUDGET.

No alteration under the recent Budget is to be made in indirect taxation, and direct taxation is responsible for the only two changes which are to be made—viz., a reduction of 3d. in the pound in income-tax on the "earned" portion of incomes which do not exceed £2000 from all sources (the "unearned" portion and incomes, which exceed £2000 still paying 1s. in the pound), and the raising of the death duties on estates of over £150,000. The differential treatment accorded to the "earned" portion of incomes which do not exceed £2000 from all sources will appeal particularly to

members of the medical profession, for the number of medical men dependent for their income upon their professional work, and not receiving £2000 per annum in return for the work is proportionately large. The relief afforded to them by the reduction of 3d. in the pound will be very welcome, but we advise them strongly to see that their accounts are kept in such a way as to show the extent to which they can benefit. Certain alterations are to be made in the matter of the return of incomes. Everyone will be required to make a declaration and to return the amount of his income, even though it is all taxed at the source, and those claiming at the lower rate of 9d. will be required to make their claim before the end of September in each year. Penalties will also be increased and the period of recovery will be extended in cases of evasion. Returns will also be demanded from all employers, requiring them to give not only the names as at present but also the salaries of all their employees. This latter requirement will not particularly affect the practitioner, nor will the increase in the death duties cause the majority of our profession much anxiety. It seems to be taken for granted that a tax of 1s. in the £ is to be the normal tax for the future upon all unearned incomes, even in times of peace. We see that there can be no material reduction of the tax whilst the present Government is in power, pledged as it is to many schemes of reform; but we make this comment in no political spirit, for it is doubtful if any sound Government could introduce a more economical scale of national living in view of the changed conditions of modern life. Whatever party or group of parties comes to power the evolution of our civilisation will be along lines leading to increased expense; and so long as the developments work for the better health and the happier life of the community, so long will the medical profession second the efforts of our legislators.

THE ACTIONS OF FORMIC ACID AND THE FORMATES.

In view of the attention which has been drawn recently to the therapeutic uses of formic acid and the formates it is of interest to refer to a somewhat remarkable book¹ which we have received from Dr. Clement of Lyon dealing with the history of the use of these substances and describing their actions. He claims that these compounds have a musculo-tonic action, increasing the force of contraction and the resistance to fatigue to such an extent that, as determined by Mosso's ergograph, the work done under their action may be five times that under normal conditions. The action is, moreover, not confined to striated muscle, but is equally remarkable upon the non-striated muscular fibres. Dr. Clement claims that after the administration of formates the subjective sensations experienced, usually within 24 hours, are those of a sense of firmness of the muscles and capacity for effort, with an absence of sensation of fatigue and weariness even after prolonged exertion or hard work. He further maintains that the circulation is improved, the respiration is deeper and slower, while the dyspnoea after exertion is markedly lessened. As an instance of its tonic action upon non-striated muscle the effect of formic acid upon the contraction of the bladder of old people is described, since in them it augments the power of the vesical wall and facilitates the act of micturition. It is also said to possess a diuretic action, especially in the form of potassium formate. Analysis of the urine showed that 62 per cent. of the dose given is excreted by the kidney. M. Huchard, who has tested the drug at Dr. Clement's

¹ L'Acide Formique et la Force Musculaire (Formic Acid and Muscular Power). Par le Docteur Clement de Lyon. Paris: Vigot Freres, 1905.

recommendation, confirms its musculo-tonic and diuretic activities and has observed a marked increase in the amount of urine passed by a patient with mitral disease after its administration. Dr. Clement has also obtained good results in certain cases of muscular tremor, notably those associated with enfeeblement of the muscles or hypotonus. A noteworthy advantage of the formates is their lack of toxicity; experiments prove them to be no more poisonous than common salt. Moreover, Dr. Clement has taken formic acid himself daily for two years with nothing but benefit. The substance may be given in the form of the acid itself or in combination as a formate. The manner of using the acid is to administer from four to six grammes of a 50 per cent. solution diluted with water to a third of a litre or a litre, according to taste, the fluid being sweetened or flavoured if necessary. This is divided into two parts and half is taken before breakfast, the other half before the mid-day meal. In case this quantity of acid is disagreeable, it is easy to neutralise it by bicarbonate of soda, the fluid being taken as soon as effervescence is completed. Or the prepared salt sodium formate may be given in daily doses of from three to four grammes. The idea of utilising formic acid was suggested to Dr. Clement by the extraordinary activity of the common ant. He finds that formic acid was a constituent of some of the complex medicaments of former days, notably in Hoffmann's "Elixir of Magnanimity," but it seems probable that formic acid derived from the bodies of ants was used some time before the beginning of the seventeenth century. Dr. Clement is very enthusiastic about the value of formic acid and its compounds and suggests that it will be found to have a social value as well as a medicinal in increasing the working capacity of mankind and in replacing alcohol in conditions of exhaustion and fatigue. His book is an interesting, if sanguine, presentation of his views, and since some of his contentions have been confirmed by other observers it would seem that these substances are worth a more extended trial than they have yet received.

THE OUTLOOK IN MEDICINE.

THE address delivered by Dr. James Grey Glover before the North London Medical and Chirurgical Society on April 11th, which we print on another page under the title "The Outlook of the Medical Profession: Scientific, Social, Financial," cannot fail to awaken the interest of our readers, for all of us have at heart the well-being of our profession, though we may differ at times as to the steps which should be taken to secure it. It is a matter of satisfaction that Dr. Glover, who has devoted so many years of service to the general practice of medicine, and who has held office in the General Medical Council in circumstances which must have given him an extensive knowledge of its many aspects, is able to conclude a comprehensive survey of the professional outlook with these cheering words: "Had I my life to begin again I should study medicine for the intense interest of it, for the companionship of it, and even for the security of a modest income which every earnest and enthusiastic and fairly intelligent man may expect." In spite of the recognition of the disabilities and hindrances which beset the path of the practitioner of medicine, a like cheerful note runs through the whole address, which has been prompted in spirit by the recent action of a French plébiscite of 15,000,000 voters who acclaimed as the greatest Frenchman of the last century Louis Pasteur, the supremacy of his position above that of Napoleon I. being clinched by the verdict of an enormous majority. This great popular voice might well hearten a reviewer of the prospects of medicine as a profession, for if the children of a land where the idea of "*la gloire*" has hitherto been inseparable from that of "*l'armée*" will thus

acclaim the healer above the soldier it may well seem that the civilisations of the future will exalt the healing art into the front rank of honour. We in this country have not yet arrived at the point of sympathy towards scientific achievement which has been reached by at least two other European nations, but the general tributes lately paid to Lord Lister, whose original and patient genius led him to apply to practical surgery the discoveries of Pasteur, show that the public mind in our matter-of-fact country has really been stirred by the story of the development and achievements of antiseptic surgery. The achievements of Pasteur and Lister are the source of Dr. Glover's optimism and those of us who have lived whilst these men were working have undoubtedly witnessed a new birth of medicine. Let us add the name of Virchow with his illuminating conception of a rational pathology and the three—Pasteur, Lister, and Virchow—will stand as witnesses that in the nineteenth century the claims of our profession to the possession of a science no less than an art were set upon permanent foundations. So far, then, we are in accord with Dr. Glover; he has right reason for rejoicing in the scientific advance of his profession. Can we look with equal satisfaction on the social or ethical aspects to which he next draws attention? Into these sides of the professional life many reforms have come, but also there have crept many defects which combine to weigh heavily on the general practitioner and which in some instances have sufficed to handicap him as heavily on the social and financial sides as the medical renaissance we have alluded to above has helped him in his scientific knowledge and treatment of disease. The matters at fault are fairly and clearly indicated by Dr. Glover under their familiar heads and we need not here recapitulate them; we have on previous occasions dealt individually with them and many attempts have been made to remedy them. Dr. Glover's suggested remedy for them all is simple enough and very wholesome—namely, self-help, but self-help is not enough. It is an individual virtue and the medical profession requires, if social development is to keep step with scientific, corporate action upon agreed lines. By all means let the practitioner pay detailed attention to little maladies as well as great; certainly, this will minimise the chances that his patients will drift off into the hands of unqualified persons. It is, moreover, his plain duty, for the little maladies taken early and treated less for what they are than for what they may signify are the finger-posts upon the track of preventive medicine. But the profession as far as the other grievances detailed by Dr. Glover are concerned must face with a united front the abuse of medical charities, the competition of half-qualified persons, and the tyranny of such medical aid societies as are not as reasonable in their actions as their delegates may be when sitting in council. A majority among the medical profession who will face these problems with the cheerful common-sense shown by Dr. Glover is not sufficient for our growing social needs. There are many medical men now ready to act together instead of complaining singly, but the much-needed reforms will not follow until the public interest in the well-being of the medical profession is thoroughly aroused.

MR. G. B. MORGAN AND THE SUNDERLAND INFIRMARY.

ON April 16th an interesting ceremony took place in the Sunderland Infirmary, the occasion being the presentation by the committee of that institution of an illuminated address to Mr. George B. Morgan, who is the senior surgeon, who has been connected with the institution for 50 years, and who for 37 years has held the post of chairman of the medical board. This is a record of which any man.

might well be proud and we join with the committee in congratulating Mr. Morgan and the infirmary upon such an extended term of service. The chairman was Mr. Alderman S. Richardson, who in making the presentation referred to the various improvements which Mr. Morgan's enthusiasm had led to. Through him, for instance, Mr. J. S. G. Pemberton had been led to see the need for a children's hospital and also to give the land for such a building. The introduction of Hospital Sunday and of workmen's subscriptions were also due almost entirely to Mr. Morgan. Many others spoke, amongst them Mr. T. F. Hopgood, a member of the medical staff, who pointed out that to Mr. Morgan was mainly due the abolition of the ticket system, while another point was the improving of the nursing. In reply, Mr. Morgan, after first thanking his friends for their kindness, gave some interesting reminiscences of Sunderland and the infirmary when he first knew it as house surgeon in 1857. Altogether the occasion was a memorable one, both to Sunderland and to the medical profession in general.

A CASE OF LOCAL ANTHRAX COMPLICATED BY PNEUMONIA.

THE circumstances relating to the death of a warehouseman in the employ of a firm of mohair spinners at Bradford were recently investigated by the Bradford city coroner and after some discussion the jury eventually found that death occurred from pneumonia, probably accelerated by anthrax. The history of the case is briefly as follows. A warehouseman, aged 55 years, employed in rooms used for the storage of tops, noils, and waste, complained on March 23rd of feeling unwell and of some slight swelling about his left eye. He was seen by Dr. F. W. Eurich, bacteriologist to the Bradford Investigation Board, which was recently founded to inquire into the increasing frequency in the neighbourhood of cases of anthrax. On March 29th Dr. Eurich found a typical malignant pustule over the left eye involving both eyelids. There was considerable elevation of temperature and signs of disease were observed at the base of the right lung. He subsequently saw the man in consultation with his own medical attendant. The patient was given antitoxic serum to the total amount of 40 cubic centimetres and appeared to hold his own until the evening of April 1st when jaundice supervened and he sank rapidly, dying in delirium on the following day. Dr. Eurich, with the assistance of Dr. Mitchell, made a post-mortem examination and found after bacteriological and microscopical investigation that the pustule was due to local anthrax, but the lung condition was pneumonic, no anthrax bacilli being found in it or in any other of the internal organs. He gave as his opinion that the cause of death was pneumonia, the local anthrax having probably lowered the patient's resisting power. The case is an exceptional one, in the accidental complication of local anthrax by pneumonia, producing grave symptoms and signs very similar to those of the pulmonary form of anthrax and leading to a fatal issue, and also in the association of jaundice, which is recognised as a rare complication of lobar pneumonia, especially when the right lower lobe is involved. The case further illustrates the risks encountered by those engaged in dealing with imported hides, skins, wools, and hairs, even when extreme care is exercised, and enforces the necessity of rigidly carrying out every possible precaution. It came out in evidence that during the last week of his employment the deceased had been engaged in manipulating Turkey and Cape mohair. This mohair had been opened over an efficient sorting board as prescribed by the regulations, and before it reached him had been sorted, washed, and combed, so that it was presumably clean and free from dust. The coroner stated that he was informed

by the Inspector of Factories that the firm who had employed the deceased were second to none in their strict adherence to the regulations, and that they were always willing and anxious to comply with any suggestion made to them. Although in this case death was not directly due to anthrax there is a reasonable probability that the pustule would exert an unfavourable effect upon the course of a disease so serious in itself as pneumonia. The Government regulations require that the sorting of wools shall be carried out over perforated tables with a downward exhaust ventilation, that the dust shall be burnt, and other precautions carried out, but the present case shows that even these are insufficient where dangerous infected wools are concerned. At present the importation of infected material cannot be prevented, while bales of wool are received from certain districts containing inferior and infected fleeces concealed within the bundles, and until some means of overcoming this fraud is forthcoming cases of industrial anthrax are liable to occur in spite of every care and precaution.

UNIFICATION OF THE PHARMACOPŒIAL FORMULAS FOR POTENT DRUGS.

IN THE LANCET of Feb. 23rd, p. 527, reference was made to an international agreement respecting the unification of the pharmacopœial formulas for potent drugs, signed at Brussels on Nov. 29th, 1906. A report has been submitted to the Pharmacopœia Committee of the General Medical Council by the committee of reference in pharmacy, showing what changes in the next issue of the British Pharmacopœia will be necessary to give effect to the international agreement. These changes chiefly affect the strength of preparations of potent drugs and aim at producing uniformity of strength in all countries whose Governments have signed the agreement. Tincture of aconite, which is to be made from roots that have been kept not longer than one year, will be standardised to contain 0.05 per cent. of total alkaloid. In the case of belladonna leaves the drug is to be restricted to the dried leaves, not including, as at present, the flowering tops. The tincture of belladonna is to be prepared from the leaves instead of the root, but the strength would be about the same as now—viz., 0.05 per cent. of total alkaloid. At present there are two official extracts of belladonna, but it is proposed to retain only the leaf extract and to standardise it to contain 1 per cent. of alkaloid. With regard to the other preparations of belladonna, it is proposed that the present standardised liquid extract of the root should be retained and that the liniment, ointment, plaster, and suppository of belladonna should be made from it as at present. It would be necessary to prepare the liniment from belladonna root owing to the high colour of preparations of the leaf, which would render the liniment unpleasant to use. In the case of hyoscyamus the leaf only is to be used for making galenical preparations. It is imperative that the extract of hyoscyamus should be standardised, as all green extracts are liable to vary considerably, and sometimes to a dangerous extent, in alkaloidal content. In the case of nuxvomica the retrograde step has been taken of standardising the seed to contain 2.5 per cent. of total alkaloid. Standardisation to total alkaloid does not insure the presence of any strychnine whatever. The proportion of strychnine to brucine in the total alkaloid has been shown to vary from 1:1 to 1:1.8, from which it follows that the genuine seed, passing the test laid down in the agreement, may vary as much as from 1.0 to 1.4 per cent. in their toxicity. At present the British Pharmacopœia requires preparations of nuxvomica to be standardised on the basis of the strychnine present and in this instance it is very probable that the British Government will be advised to assert its right by Reservation IV. of the agreement to make such modifications in detail as the progress of

science may from time to time render necessary. The time-honoured official name of *Dover's powder*, *pulvis ipecacuanhæ compositus*, will in future be replaced by the more descriptive name, *pulvis opii et ipecacuanhæ compositus*. In many cases the adoption of the standards agreed upon will considerably increase the strength of official preparations of potent drugs. It is agreed that tinctures of potent drugs shall be prepared of the strength of 10 per cent. and fluid extracts of the strength of 100 per cent. As a result tincture of *strophanthus* will be made four times as strong as the present tincture, the strength of tincture of *cantharides* will be increased rather more than six and a half times, that of ethereal tincture of *lobelia* twice, and that of tincture of iodine three and one-third times, while tincture of opium would be made one-sixth stronger than at present. In the case of tincture of iodine much trouble may result from the large increase in strength of a preparation so widely used for external application. The strengths of the following preparations will be reduced: tincture of *colobicum* seeds by one-half, tincture of *digitalis* by one-fourth, tincture of *nux vomica* by one-half, and syrup of ferrous iodide, the strength of which will be considerably diminished. The strength of mercurial ointment will have to be reduced by rather more than one-third, an alteration which will correspondingly affect the various preparations into which the ointment enters. These alterations in the strength of official preparations will involve corresponding alterations in the doses, and in some cases great care will have to be taken to avoid serious mistakes through the administration of excessive doses. This is particularly the case with tincture of *strophanthus*, which when increased in strength will have a dose of from one to five minims. As indicated in the annotation referred to above the various changes proposed will not come into effect until the publication of a new British Pharmacopœia.

THE SOILING OF THE OMNIBUS FLAG.

Two years ago when discussing the hygiene of the London streets in relation to the increasing motor traffic we remarked, with an obviousness that is more apparent now than it was then, that whereas the chief source of the pollution of the streets was the excreta and emanations of horses it would be in the near future the products of perfect and imperfect combustion of petrol. This prediction was soon realised and we have now to face the new pollution and to consider whether it is worse than the old. Previously the pollution was chiefly biological, now it is chemical, or, to be accurate, it is both, with a rising tendency in the latter direction. Pathogenic organisms may therefore give way to poisonous gases, but hygiene condemns the existence or encouragement of either. On the whole we think that, owing probably to the increased vigilance of the police authorities over the motor traffic, the nuisance arising from fumes and smell of imperfectly ignited petrol or of over-heated lubricating oil has been reduced for the moment to some extent. There is a daily test being carried on (no doubt unwittingly) by at least one of the motor omnibus companies which seems to us to be faithfully recording the fact that the air of the London streets is not so clean as it used to be. We refer to the flag carried as a distinguishing mark by certain motor omnibuses. There is not the least doubt that the colours of this flag are besmirched much more quickly than in the days of universal horse-drawn traffic. In many cases the flag is practically black and the pattern can barely be recognised. This result is hardly surprising when we consider the miles and miles of street air into which motor gases and smoke are being discharged and through which the tell-tale flag is daily

trailed. We should not be surprised to find that in treating this smoke-begrimed flag with a suitable solvent a greasy extract would be obtained having a smell which might fairly be traced to petrol. In connexion with this point we may refer also to some complaints which we have heard from householders and house decorators that since the great increase in motor traffic the external paint of many houses has shown more rapid signs of deterioration than was ever experienced before. It is easily conceivable that an atmosphere containing oily fumes would attack the oil of the paint and thus expose the lead compound to the blackening action of the sulphur present in the smoke discharged from the chimneys.

STATISTICAL INVESTIGATIONS OF PULMONARY TUBERCULOSIS.

UNDER the title of "A First Study of the Statistics of Pulmonary Tuberculosis," Professor Karl Pearson of the Biometric Laboratory, University College, London, has contributed an interesting paper to the Drapers' Company Research Memoirs (Studies in National Deterioration).¹ The investigation in question is based upon a series of family histories placed at Professor Pearson's disposal by Mr. W. C. Rivers of the Crossley Sanatorium, Frodsham, Cheshire. The records were made by the medical men of that institution and applied in both subject and family history to cases of pulmonary tuberculosis only. The patients were almost wholly of the lower middle and working classes and came principally from Manchester. Questions relating to various aspects of heredity are the leading subjects of the present paper and may be conveniently summarised under the headings of (1) the inheritance factor in pulmonary tuberculosis; (2) fraternal heredity; (3) the fertility of tuberculous stocks; and (4) the distribution of pulmonary tuberculosis in tuberculous families. It will here be sufficient to give a brief abstract of what is said on the subject of the parental transmission of the tuberculous diathesis. In using the data obtained from Crossley Sanatorium as a basis of computation it is at the outset remarked that pulmonary tuberculosis is a disease the frequency of which culminates between the ages of 20 and 30 years. Hence many patients, if members of large families, have brothers and sisters who have not yet passed or have perhaps even not yet reached the danger zone. The number of brothers and sisters of a patient who are also tabulated as suffering from the disease is therefore a minimum limit and not a real measure of the extent of the disease in a family. For this reason, although the actual Crossley records only show about 32 per cent. of the offspring of tuberculous parents to be themselves tuberculous, 50 per cent. is the proportion adopted in the computations, and the further assumption is made that the proportion of tuberculous persons in the community at large is from 10 to 13 per cent. From all these figures several values of the correlation coefficient (r) are obtained by six biquadratic equations of the form

$$A = r + Br^2 + Cr^3 + Dr^4,$$

the constants which we have called A, B, C, D, being represented by various positive and negative numbers lying between 1.155432 and 0.017452. From the values of r so obtained Professor Pearson concludes that the intensity of the inheritance factor in pulmonary tuberculosis is greater than 0.4 and less than 0.6—an inheritance factor closely approaching that of certain physical characters in man. He is convinced that the perpetuation of the disease in families cannot be explained by infection but only by the inheritance of the tuberculous diathesis, and he complains of the "anti-social disregard for national eugenics in the conduct of medical men who can write to the public press that the marriage or

¹ Published by Dulau and Co., 37, Soho-square, London, W. Price 3s.

even intermarriage of members of tuberculous stocks is of no social detriment, provided they live with a good supply of fresh air." An interesting point subsequently touched on is the heavier incidence of tuberculosis in the older offspring of tuberculous parents as compared with the younger offspring.

PERICOLITIS.

In the *Medical Chronicle* for April Mr. W. H. Newton publishes a graduation thesis on Pericolicitis, a condition which has received little attention, and its literature is still very scanty. In 1890 Windscheid first described a disease characterised by acute swelling on the right side of the abdomen, fever, and pain which he thought was due to circumscribed peritonitic exudation around the ascending colon.¹ Pericolicitis may occur in any region of the colon. The commonest site is the descending colon, especially the lower part. Dr. H. D. Rolleston has described this form as "Pericolicitis Sinistra"—a condition which produces symptoms resembling those of appendicitis but on the left side of the abdomen. In the majority of cases constipation plays a prominent part in the production of pericolicitis but in some cases there is no history of it. Of the pathology little can be said, because there is a lack of post-mortem data. Dr. Rolleston suggests that faecal accumulation gives rise to inflammation of the mucous membrane and other coats of the colon and, by extension to local peritonitis. There is an objection to this view; inflammation of the mucous membrane would probably cause diarrhoea but in the majority of cases constipation exists. A hypothesis which escapes this objection is that hard faecal masses cause small tears or abrasions of the mucous membrane and allow the passage of microbes into the sub-mucous tissues, whence they are carried by the lymphatics into the connective tissue surrounding the colon and set up inflammation. This is comparable to the spread of inflammation from the uterus in perimetritis. Another hypothesis is suggested by the fact that in a certain proportion of the subjects of constipation acquired diverticula of the colon are found. The faeces tend to accumulate in, and to enlarge, these diverticula. Thus, a condition somewhat resembling that of the vermiform appendix arises and an inflammation analogous to appendicitis may occur. Severe inflammation may occur around a diverticulum and an abscess may be formed or perforation of a diverticulum into the peritoneal cavity may take place, producing general peritonitis. Another cause of pericolicitis is injury. In two cases recorded by Mr. D'Aroy Power there was a history in one of kicks and in the other of blows on the abdomen. Other causes are leakage from ulcers (typhoid or stercoral) of the colon. As pointed out by Dr. Rolleston, the symptoms may be divided into three groups—(1) those of slight local peritonitis; (2) those of local abscess; and (3) those of general peritonitis. In the case of the first group resolution may occur, leaving no trace of the inflammation, or the inflammation may become chronic. But intestinal obstruction may result. Mr. W. Arbuthnot Lane has stated that he has often seen on the operating table the ascending colon, especially near the hepatic flexure, bound down to the abdominal wall by adhesions the result of constipation.² Some cases, he says, have been operated on under the diagnosis of appendicitis; the appendix was sometimes found normal, sometimes slightly diseased. After its removal the symptoms continued and were relieved by dividing adhesions around the hepatic flexure of the colon. Similar adhesions may also occur in the descending colon. The treatment in simple cases consists of rest in bed and the relief of the constipation by enemata, or

the removal of scybalous masses by mechanical means be necessary. If the pain is severe hot fomentations or application of an ice-bag may be required. In the cases with adhesions it may be necessary to open the abdomen and to divide the adhesions. Afterwards the bowels must be kept freely acting, for if the constipation re-adhesions may re-form. In intractable cases Mr. Arbuthnot Lane has advised anastomosis of the ileum to the sigmoid flexure or rectum. In cases of abscess the abdomen should be opened and the abscess drained. In cases of general peritonitis immediate closure of the perforation and drainage of the abdomen are indicated.

THE EPIDEMIOLOGY OF MALTA FEVER.

Colonel David Bruce, R.A.M.C., has summarised succinctly the remarkable results obtained by the commission sent to Malta by the Royal Society to investigate and if possible to find out the cause of Malta fever.¹ Colonel Bruce passes in review all the chief peculiarities of the disease; as regards its geographical distribution he shows how it has disappeared from Gibraltar and how it is found in South Africa, China, India, the Philippine Islands, and America. The clinical symptoms are briefly detailed, such as its long, irregular temperature curve and the presence of rheumatic and neuralgic features. It has long been known also that the better the social position the greater is the liability to the disease. It is a disease prevalent all the year round in Malta, although markedly increasing in summer. It is not, as until recently was supposed, restricted to the neighbourhood of the Grand Harbour, but is very generally distributed over the entire island. How great is the invaliding caused by it is manifest from the yearly incidence of 37·6 per 1000 amongst the soldiers and 28·5 per 1000 amongst the sailors, and as the average duration of the illness is four months, 624 soldiers and sailors are in hospital 120 days, which makes 74,880 days of illness. The members of the commission set to work to determine how it was that the micrococcus *Melitensis* left the body, how it behaved outside the body, and how it again gained entrance into the body, and as the result of their inquiries they determined that it left the body by the urine. Outside the body the organism was found to be fairly resistant to external influences, except to direct sunlight which killed it in a few hours. Does it gain an entrance by contact? No case has been known of its arising among the patients, orderlies, or nursing sisters from any of the patients invalided home to our naval or military hospitals. The commission also failed to find any evidence that inhalation of infected dust or mosquitoes played any prominent part. But Malta fever can be conveyed to healthy animals by way of the alimentary canal. A single drink of fluid containing but few micrococci almost certainly gives rise to the disease. But the commission at first saw no reason for suspecting the water-supply or any particular foodstuff. At length, however, it was discovered that the goats in Malta acted as the reservoir of the virus of this fever, for 50 per cent. of these animals in Malta responded to the agglutination test and actually 10 per cent. were found to be secreting the micrococcus in their milk. Monkeys fed on milk from an infected goat, even for a day, almost invariably took the disease. The example of Gibraltar clinches this opinion that the infection is propagated by the goats, for the disappearance of Malta fever from the Rock is associated with the disappearance of the Maltese goat from the Rock. Preventive measures in accordance with this discovery were begun in Malta in June, 1903, and a remarkable diminution of the fever at once set in;

² THE LANCET, April 1st, 1905, p. 856.

³ THE LANCET, Jan. 17th, 1903, p. 153.

¹ Recent Researches into the Epidemiology of Malta Fever. By Colonel David Bruce, O.B., F.R.S., R.A.M.C. (reprinted from the Journal of the Royal Army Medical Corps, March, 1907). London: John Bale, Sons, and Danielsson, Limited. 1907. Pp. 11.

the cases have dropped to one-tenth of what would have been their normal number, whilst since goats' milk has been forbidden in the Royal Naval Hospital not a single case has occurred or can be traced to residence in the hospital. The commission of the Royal Society would thus seem to have made a most valuable discovery. Colonel Bruce considers that Malta now has a chance of being converted from one of the unhealthiest stations of the British navy to one of the most salubrious, and the expectation is founded upon solid arguments. The Royal Society and the members of the commission are to be congratulated on the investigation.

A TWIN OVUM IN A TUBAL PREGNANCY.

IN THE LANCET of March 30th, p. 881, Dr. Allan F. Rutherford described a very interesting case of a twin ovum in a tubal pregnancy which he had removed by abdominal section. This condition is one of considerable rarity but a sufficient number of cases have now been recorded to show that in this variety of multiple gestation the two ova may be situated in the same tube, or one in either tube, or an intra-uterine may be associated with an extra-uterine pregnancy. When the two ova are found in the same tube most commonly there is one foetal sac common to the two. Unfortunately, it is not quite clear from the description of Dr. Rutherford's specimen whether the two ova were contained in a single chorion with a single placenta or not, although the illustration shows that each foetus was inclosed in its own amnion. A not inconsiderable number of cases have now been described of a tubal twin pregnancy with a single foetal sac, but very few have been met with in which the two ova in separate sacs were attached to different portions of the same tube. Some instances of this arrangement have, however, been reported, one of the earliest being that of Boehmer cited by Webster, in which the tube was enlarged in two different parts, one of which contained an early ovum and the other an ovum converted into a mole. In a case recorded by Saniter one ovum was situated in the isthmal portion of the tube and had apparently reached the third or fourth week of development, while the other sac in the neighbourhood of the abdominal ostium contained an ovum four centimetres long. Twin ova enveloped in the same foetal sac form, as we have said, the commonest variety and have been found not only in the early but also in the later months of an extra-uterine gestation. In a case described by Krusen the condition was one of triplets, the three foetuses, all about the second month of development, being found in the blood mass of a hamatocoele, the burst sac occupying the ampulla of the tube. In a most remarkable case recorded by Folet, in which the extra-uterine sac probably had existed for some 18 years, both foetuses were mummified. One had attained almost full term, while the second, which was flattened out against the sac wall, was of the size of a three months foetus; there was a single placenta. That the foetuses in most of these observations are of very different degrees of development is no doubt to be explained by the imperfect growth of the two placentae, the direct result of their extra-uterine attachments, since unequal development of twins in utero is of relatively uncommon occurrence. The third combination in which both tubes are involved in the pregnancy has so far only been met with in the early months of pregnancy. One of the best known cases is that of Walter; in this instance both tubes contained a hamatoma in one of which there was a foetus six centimetres long in the amniotic cavity, whereas in the other the amniotic cavity was compressed and empty in the middle of the blood mass. In a case recorded by Werth an operation undertaken for the removal of a hamatocoele of recent formation revealed the presence in the opposite right tube of an unruptured tubal gestation. In another case operated upon by the same surgeon the left tube contained a

hamatoma and the right tube, the abdominal end of which was closed by old adhesions of some standing, a foetal sac with no trace of any embryo. In this case it appears probable that the ovum contained in the right tube may have come from the left ovary by internal migration, judging by the fact that the obliteration of the abdominal end of the right tube appeared to date from a period anterior to the commencement of the twin tubal pregnancy. These varieties of multiple pregnancies are of much interest and all such cases should be carefully recorded.

EPIDEMIC CEREBRO-SPINAL FEVER.

THE epidemic of cerebro-spinal fever continues without much alteration in its incidence. In London during the last few days one case has been reported in the borough of Finsbury and one in the borough of Stepney. Since March 26th, when the order requiring the notification of the disease came into operation, 24 cases have been reported to the London County Council. Cases have also occurred at Liverpool, at Smethwick in Staffordshire, at St. Germans in Cornwall, at Chilvers Coton in Warwickshire, at Whitwell in Derbyshire, at Newburn in Northumberland, at Wrexham in Denbighshire, and at Crewe in Cheshire. In Scotland during the week ended April 20th there were 18 deaths from the disease registered in Glasgow, ten in Edinburgh, six in Leith, two in Greenock, and one in Dundee. The weekly return of the Glasgow sanitary department issued on April 19th showed that there were at that time 112 cases under treatment. In Edinburgh from March 1st to April 22nd there were 66 cases with 42 deaths. Other cases have occurred at Plains near Airdrie, at Haddington, at Kirkcaldy, and at Kirkintilloch. In Belfast 30 fresh cases have been reported during the past week. There has now been in this city a total of 313 cases with 200 deaths.

FURTHER EFFECTS OF RECENT LEGISLATION ON THE DRUG TRAFFIC IN THE UNITED STATES.

IN the March number of the *American Journal of Pharmacy* further evidence is given of the salutary effects of the Pure Food Act, to which reference was made in THE LANCET of Feb. 9th, p. 373. Since the Act has become effective the products of certain large packing houses, which were formerly labeled "potted ham" or "potted tongue," now bear the names "potted meat, ham flavour," and "potted meat, tongue flavour." The substance has not been changed but it is now designated by its right name. Again, for many years the public in the United States have been deceived into buying coffee from which "the poisonous caffeine and the poisonous tannic acid have been removed." Preparations such as these are impossible to prepare without completely destroying the properties of the coffee and it is satisfactory to find that under the new law they are amenable to the section on misbranding. Turning to drugs, one of the most important effects of the Act consists in the numerous changes that have been made in well-known nostrums which formerly contained alcohol, morphine, cocaine, chloral hydrate, cannabis indica, acetanilide, and other drugs of a poisonous nature named in the Act. As a declaration of the presence of any of these drugs must now be made on the label the manufacturers have generally altered the formulae rather than admit their presence. The medical profession as much as the public has been fooled in this way. Mixtures of acetanilide and other ingredients which were formerly exploited as definite chemical compounds are now being sold as mixtures and, in some cases at least, their composition has been totally changed. Thus, ammoniac now bears upon the label the name "ammonium phenylacetamid" and it is

admitted to contain "240 grains of paracetyl-phenetidin" (in plain English, phenacetin) in each ounce. In regulating the sale of narcotic drugs a strong blow has been struck at one of the most insidious evils of the nostrum traffic. Instances have come before the authorities at Washington, e.g., in the case of several remedies for catarrh, in which manufacturers have brazenly admitted the addition of morphine or cocaine to their nostrums in order that their continued use might be assured. It is almost incredible that a manufacturer should stimulate the sale of his wares in this way and grow rich by the production of thousands of narco-maniacs. But unfortunately a similar condition of things obtains in this country at the present time without a legal remedy. In regard to self-drugging, the full extent of the mischief is only known to members of the medical profession. A more stringent control of the sale of food and drugs, especially the latter, is called for in this country, but it will require strong hands to pilot a satisfactory measure. It would be easy to control the manufacturers; the main difficulty rests with the advertising managers of newspapers.

FATAL AIR EMBOLISM FROM PUNCTURE OF THE LIVER WITH AN ASPIRATING NEEDLE.

In the *Journal of the Royal Army Medical Corps* for April Lieutenant N. Low, R.A.M.C., has reported a case of a rare accident in puncture of the liver for abscess. A thin, sallow gunner was admitted into hospital on May 9th complaining of pain in the right shoulder. He had not felt well for three months. The evening temperature was 102°·2° F. The lower border of the liver could just be felt below the ribs. In the scapular line dulness extended up to the eighth rib. On the 11th the liver dulness had increased so as to extend three fingers' breadth below the costal margin. On the 13th it was proposed to explore the liver. Under chloroform an aspirating needle three inches long was inserted in the lowest intercostal space in the anterior axillary line and pushed into the liver. Instantly there was a loud hissing noise as of air being sucked in and respiration stopped. One or two feeble beats were felt at the wrist and then the pulse stopped. Lieutenant Low put his thumb over the end of the needle to prevent any further entrance of air. When the air rushed in the right side of the face twitched sharply for a moment, the pupils widely dilated, and the face became livid. Attempts at resuscitation failed. At the necropsy one and a half pints of blood were found in the peritoneal cavity. The right cavities of the heart were filled with frothy blood and air bubbles. The base of the right lung was adherent to the diaphragm above an abscess in the right lobe of the liver. The liver was much enlarged and weighed 116 ounces. The needle puncture was in the right lobe two inches above the lower margin; a small clot adhered to it. On cutting down upon a probe passed into the wound it was found that a large branch of the portal vein had been opened. On squeezing the liver frothy blood and air bubbles issued from the vein. The upper portion of the right lobe was occupied by an abscess of the size of the foetal head, containing 32 ounces of pus and surrounded by a fibrous wall a quarter of an inch thick.

THE Oliver-Sharpey lectures of the Royal College of Physicians of London will be delivered by Dr. W. D. Halliburton on Monday and Tuesday, April 29th and 30th, at 5 o'clock, at the College, Pall Mall East, the subject being *New Facts in Relation to the Processes of Nervous Degeneration and Regeneration*.

THE Department of Public Health of Queensland in a bulletin dated March 16th reports a case of bubonic plague in a male aged 23 years, who was attacked on

March 10th. In the same bulletin the health officer of Port Douglas reports 6 fresh cases of plague admitted to the hospital during the week ending March 16th. As regards the Mauritius a telegram from the Governor received at the Colonial Office on April 19th states that during the week ended April 18th there were 2 cases of bubonic plague and no deaths from the disease.

WE have several times alluded to the fact that a committee has been sitting to discuss the possibility of starting a coöperative plan by which medical men can be insured upon favourable terms against the risks of the Workmen's Compensation Act, 1906. The negotiations with various insurance companies have been tedious, but the definite result of the work of the committee will shortly be published.

THE INTERNATIONAL BUILDING TRADES EXHIBITION.

THE International Building Trades Exhibition, which was held at Olympia from April 8th to 20th, was a great success and we take pleasure in recording this fact since the exhibits in so many instances were striking illustrations of hygienic advances. Public health, indeed, was written large on almost every stall, and the visitor intent on acquainting himself with new departures in sanitary applications in relation to house construction ought to have been very pleased with what he saw, while a satisfactory feature of the exhibition was that the demonstrations were in many instances illustrative of the attempts being made to bring domestic comforts framed upon sanitary principles within the reach of the poorer classes. A very interesting section also which concerns the comfort of us all was that known as the "Surveyor" section in which were shown examples of the way in which roads are "metalled" and of the attempts to deal with motor problems. Besides, there were illustrations and working models of water-supply, refuse collection and disposal, sewage disposal, and other departments of municipal engineering work.

We do not pretend to give more than a short reference to those exhibits which seemed to us to be of direct sanitary significance, seeing that in the words of the organisers "the whole of the spacious building, ground floor, gallery, and even the annexe, was crowded to the last available inch with exhibits—a record for a trade exhibition in any part of the world." It speaks well for the energy of those responsible for it that such an exhibition should have been got together, but one disparaging word we are bound to add: the ventilation of the vast building left much to be desired. The interest of the exhibition was marred by a stagnant impure air; the crowd of visitors was great and many complained of a splitting headache, which may safely be attributed to the dust and foul air present.

Amongst the first exhibits brought to the notice of the visitor were specimens of a beautiful material for rendering floors fireproof shown by the Stonwood Fireproof Flooring Company, Limited, of 109, Victoria-street, Westminster, London, S.W. The floors are stated to be warm to the feet, fire-resisting, and proof against water and dampness. They have been employed in hospitals, schools, and factories. Illustrations of the application of fireproof sheeting known as Dovetail corrugated steel sheeting were given by the Fireproof Company, Limited, of 10, York Buildings, Adelphi, London, W.C. A device for obviating dampness and decay was exhibited by Mr. A. W. Andernach (agency, 30, Patshull-road, Kentish Town, London, N.W.), consisting of the Kosmos grooved slabbing, as it is called, which acts by encouraging a circulation of air in the walls themselves. Specimens of slag wool and silicate cotton as a vehicle for fireproof partitions were shown by Messrs. Fred Jones and Company, of 1, 2, and 3, Perrin-street, Ryland-road, London, N.W. Messrs. Elkay and Comes, of Bath House, 59, Holborn Viaduct, London, E.C., have recently introduced a very ingenious folding bath in various types for mansion or cottage. The cabinet folding bath, made of enamelled sheet steel, is designed for bedrooms or dressing-rooms and when

not in use the bath tips up into the cabinet and the floor-space then occupied is 2 feet 1 inch deep and 2 feet 9 inches wide. In the same way a folding bath without cabinet is made for villas, bungalows, artisans' dwellings, servants' quarters, &c. This can be fitted in a 2-foot cupboard or in a recess. An exhibit which attracted a good deal of attention was that of Messrs. Thomas Potterton of the Cavendish Works, Balham, London, S.W. It consisted of a model of a domestic hot-water service in a large mansion worked from the "Rex" kitchen, no second fire being needed for warming the various rooms in the house, since these are provided with radiators on the same service. The Patent Adjustable Bath Company of 31, Broad-street, Birmingham, exhibited a specimen of their tip-up bath as in use at the employees' cottages at Messrs. Cadbury's works at Bourneville. The Silicate Paint Co. of Charlton, London, S.E., presented to view a model cottage decorated inside and out with "Duresco," a washable wall paint made durable, as its name implies, by a silicating process. The Newellite Glass Tile Company, Limited, of Shenton-street, Old Kent-road, London, S.E., exhibited specimens of glass tiles which, while presenting a clean impervious surface, are said to be free from the tendency to craze or crack and to be specially adapted for hospital construction. The sanitary exhibits of the Sanitary Appliances Syndicate, Limited, of 68, Victoria-street, Westminster, London, S.W., were very numerous and comprised "The Only" silent closet fitted with polished brass valve and gun-metal working parts. The utmost flush necessary is two gallons and there is no ball valve. Several modifications of this closet were shown, all designed to meet sanitary requirements and to eliminate offence; as well as gullies, tidal valve and traps for drain connections, inlet air valves, urinals with hand-flushing arrangement, flushing cisterns, and domestic water tanks possessing some claim or other from a hygienic standpoint. Examples of Hall's washable sanitary distemper were given at the stall of Messrs. Sissons, Bros., and Company, of 199a, Borough High-street, London, S.E., while close by were "well" fires shown in working order by the Wellfire Company of 33, Dover-street, Piccadilly, London, W. Messrs. John Knight and Sons of 24, Gertrude-street, King's-road, Chelsea, London, S.W., exhibited their cast iron inspection and disconnecting chambers for drainage work, besides their sealed internal gullies and manhole covers. Messrs. G. A. Williams and Son of 21, Queen's-road, Bayswater, London, W., brought to the notice of the visitors their patent open-air sleeping chamber and their "invisible" outside blind. The Gypsum Mines Company, Limited, of Mounthfield, Robertbridge, Sussex, showed specimens of their "Sirapite" Plaster which was used in the London hospitals for restoring interior walls and as a backing for glazed tiling. The patent bucket fire extinguisher of Messrs. Messer and Thorpe of 54, 56, and 58, Gedling-street, Dockhead, London, S.E., is well worth mentioning and consists of a number of fire buckets telescoped together which can be so submerged in water that on being taken out they each and all come out full. A somewhat revolutionary and attractive proposal in regard to methods of domestic heating is that of Messrs. James Prior and Co. of the Empire Works, Holliday-street, Birmingham, who gave a working demonstration of the method of heating bedrooms and hall with the waste heat from the sitting-room fire by means of the "Venetian" grate and heat distributor. The London Warming and Ventilating Company, Limited, of 20, Newman-street, London, W., exhibited their ingenious "Florence" warm-air and ventilating grate. The smoke is drawn through the fire to a point where it becomes incandescent and the automatic shaking bins clean the fire of ashes and dust, thus providing free access of air at a high temperature through the fuel. A very handsome exhibit, comprising a series of model bathrooms with the latest patterns of sanitary appliances, was shown by Messrs. Shanks and Co., Limited, of 81, New Bond-street, London, W. The porcelain enamel used in the baths calls particularly for a word of praise. The exhibit included urinals, lavatory sinks, and basins. Messrs. Davis, Bennett, and Company of the Westminster Sanitary Works, Horseferry-road, London, S.W., exhibited a number of luxurious sanitary appurtenances, including bath-rooms, water-closets, lavatories, and so forth. The Ajax basins and sinks of the Ajax Sanitary Company, Limited, of 49, Stamford-hill, London, N., are well worthy of mention, inasmuch as these sanitary apparatus illustrate an important improvement consisting of an outlet and overflow passage in a recess at the back, front, or side, and a shutter or sliding valve. As might have been anticipated, Messrs.

Doulton and Company's exhibit (Lambeth Potteries, London, S.E.) was most comprehensive and included a really handsome display of sanitary appliances, such as bath-room fittings, lavatory accessories, water-closets, sinks, drains, and glazed pipes, besides an installation of fireplaces and mantelpieces in glazed ware.

In the "Surveyor" section Messrs. Horsfall of Lord-street works, Whitehall-road, Leeds, exhibited a model of their "tab-feed" refuse destructor, as well as of their "cupola" type destructor and a forced draught smoke-consuming furnace. The exhibit included some specimens of clinker flags, &c. Close by were various specimens of "tarmac," shown by Tarmac, Limited, of Ettingshall, Wolverhampton. "Tarmac" is manufactured from ironstone slag, impregnated with tar oils. Roads made with it are said to be free from dust, mud, or grease. The Ames-Crosta Sanitary Engineering Company, Limited, of City Chambers, South Parade, Nottingham, exhibited their sewage disposal specialities, including the "Simplex" automatic sewage sprinkler and the "Coleman" automatic sewage valve worked by a mercury balance. The "Ames" tiles also should be mentioned as a simple device for ensuring drainage and aeration of bacteria beds and for the flooring of water filter beds. The Candy Filter Company of 5, Westminster Palace-gardens, Artillery-row, Westminster, London, S.W., exhibited plans and drawings of installations of the Candy patent automatic compressed air and oxidising water-works filters as well as samples of "oxidium," a mineral oxidising substance for purifying water. At the same stall were working models of the Candy-Whittaker sewage distributor. Messrs. Ham, Baker and Co., of 13, Grosvenor-road, Westminster, London, S.W., similarly exhibited their ingenious travelling sewage distributor for rectangular filter-beds and a number of other sewage engineering appliances. "Tarspra" of Tarspra, Limited, of 20, Victoria-street, Westminster, London, S.W., is said to have solved the "dust" and "skid" problem of the roads. Hundreds of miles of roads, it is stated, can be treated with "tarspra" in a few weeks. Mr. William E. Farrer of Star Works, Cambridge-street, Birmingham, exhibited his improved automatic sewage distributor, which appears to be particularly well adapted for small installations—as, for example, country houses. Close by was a working model of the "Sterling" refuse destructor (Messrs. Hughes and Co., 7, Arundel-street, Strand, London, W.C.), which is said to do its work very effectually and without causing the slightest nuisance. An example of obtaining power from waste could be seen in the destructor of Messrs. Heenan and Froude of 4, Chapel-walks, Manchester. In the same section Messrs. George Jennings, Limited, of Lambeth Palace-road, London, S.E., exhibited a number of "up-to-date" appliances connected with the disposal of sewage, while Messrs. Defries and Son, Limited, of 146 and 147, Houndsditch, London, E.C., exhibited illustrations of their Equifer steam disinfecting appliances. The latest form is fitted with an automatic apparatus by which no record can appear on the automatic recording gauge until the evacuation of air from the disinfection chamber is complete, thus preventing disinfection from being imperfectly carried out with an admixture of air and steam.

Altogether the exhibition was of the greatest interest from a hygienic point of view, and we have no doubt that it was very generally supported and appreciated by the building trades.

BRITISH MEDICAL BENEVOLENT FUND.

At the March meeting of the committee 19 applications for assistance were considered and sums amounting to £193 voted in relief of 18 of the cases, one being postponed for further inquiries. Two annuities of £20, vacant through death, were filled by the election of approved candidates. Appended is an abstract of the cases which were helped:—

- Daughter, aged 50 years, of late M.R.C.S. Health too indifferent for regular work. Slight help from a relation. Voted £5.
- Widow, aged 65 years, of L.F.P.S. Glasg. No income. Very bad health. Dependent on a daughter who is a waitress. Relieved once, £12. Voted £5.
- Daughter, aged 57 years, of late M.D. Abern. Dependent on small and decreasing earnings from teaching music. Health indifferent. Voted £10.
- Daughter, aged 74 years, of late M.R.C.S. Only income five guineas a year from a charity. Health indifferent and sight failing. Voted £12.

Wife, aged 42 years, of L.R.O.P., L.R.O.S. Edin. Applicant's husband has practised for many years as assistant in Lancashire but lost his reason a few months ago and is now confined in an asylum. No income. Two children at school. Voted £15.

Daughter, aged six years, of late L.R.O.P., L.R.O.S. Edin. At father's death, two years ago, applicant had to go to the workhouse but has been removed by an uncle of extremely small means. Voted £3, payable to the uncle.

M.D. Edin., aged 68 years. Used to be well provided for but lost his capital through the failure of a home for inebriates and other misfortunes. Is now unable to practise on account of ill health. No children. Voted £18.

Daughter, aged 65 years, of late M.D. Unable to obtain remunerative work on account of age. Relieved nine times, £79. Voted £12.

Widow, aged 47 years, of M.R.O.S., L.S.A. Supports herself as a housekeeper and is obliged to help an invalid son. Relieved eight times, £100. Voted £10.

Widow, aged 35 years, of L.R.O.P. Edin. Endeavours to support herself by nursing. Two children, aged 12 and three. Relieved three times, £30. Voted £10.

Widow, aged 68 years, of L.F.P.S. Glasg. Nine children, of whom six are self-supporting and able to give a little help but three still dependent. Relieved eight times, £120. Voted £25.

Widow, aged 59 years, of M.R.C.S. Eng. No income; children unable to help; health very indifferent. Relieved once, £12. Voted £12.

Daughter, aged 64 years, of late M.R.C.S. Only income an annuity of £20 from a charity. Relieved twice, £12. Voted £3.

Widow, aged 60 years, of L.R.O.S. Edin. Income £18 a year. Receives a little help from a son. Is in very bad health. Relieved five times, £50. Voted £12.

Widow, aged 44 years, of L.R.O.P., L.R.O.S. No income; slight help from a son, who is a sailor. Relieved three times, £27. Voted £12.

M.R.O.S., L.S.A., aged 67 years. Has been incapacitated for some years by paralysis and heart disease. Receives a small superannuation allowance. Eight children, only able to give slight help. Relieved five times, £75. Voted £15.

Widow, aged 46 years, of M.B., O.M. Income £20 a year; receives slight help from her father-in-law and takes boarders. Seven children, aged 16 to eight. Health indifferent. Relieved eight times, £30. Voted £12.

Daughter, aged 49 years, of late M.R.O.S. Income £8 a year; practically disabled by an accident. Relieved once, £5. Voted £12.

Looking Back.

FROM

THE LANCET, SATURDAY, April 25th, 1829.

FOREIGN DEPARTMENT.

M. BROUSSAIS.

WE are glad to see, that the gastro-enteritido mania of our neighbours is at last gradually subsiding; indeed, whatever share M. Broussais' arrogance* may have had in securing to his doctrine the extraordinary applause it met with, this was, we apprehend, still more owing to the commodiousness of his principles. How could it be otherwise than acceptable to many, at once to render unnecessary the study of pathology and therapeutics, by proclaiming gastro-enteritis to be the only disease, and the application of leeches as the only remedy.

Our readers will be greatly amused by a description of the manner in which the medical practice is carried on at the Hôpital Val de Grace; taken from the inaugural dissertation of a young physician who attended there as a pupil.

"When I," he says, "was appointed one of the dressers at the hospital, I had but a very incorrect notion of the 'doctrine physiologique.' It having, in this capacity, become my duty to examine and prescribe for the patients, who had been admitted after the regular morning visit of the physician, I was not a little uneasy at my responsibility, until one of my colleagues set my mind perfectly at ease, by the manner in which he managed the affair. The only thing was to ask how many new patients there were in attendance, and then to order a sufficient number of leeches, to allow thirty for each patient. Thus armed, he went through his wards, where he had only the trouble of applying his leeches either to the abdomen or to the anus, an alternative which had already been settled by the 'infirmier,' who asked each patient at his entrance, whether he had diarrhoea or pain in the abdomen, and in the former case, placed a piece of oil-cloth between the legs, in the latter, over the abdomen; by these symbols, the young practitioner knew at once where to apply his thirty leeches, whether to the anus or abdomen, and, indeed, he hardly ever

had to complain of incorrectness in the 'infirmier's' diagnosis and plan of treatment."

* In the preface to the second edition, he modestly observes, that he considers his theory at least as valuable an acquisition to mankind, as the discovery of the cow-pox!

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 76 of the largest English towns 9206 births and 5149 deaths were registered during the week ending April 20th. The annual rate of mortality, which had been equal to 17·9 and 18·9 per 1000 in the two preceding weeks, further declined to 16·8 in the week under notice. During the first three weeks of the current quarter the death-rate in these towns averaged 17·2 per 1000, the rate during the same period in London being only 16·8. The lowest rates* in the 76 towns last week were 4·6 in Hornsey, 9·4 in Coventry, 9·5 in Handsworth, and 10·0 in Hastings; the rates in the other towns ranged upwards to 24·3 in Ipswich, 24·7 in Wigan, 24·8 in St. Helens, and 27·2 in Hanley. The 5149 deaths in the 76 towns showed a further decline of 47 from the numbers in the two preceding weeks, and included 506 which were referred to the principal epidemic diseases, against 569 and 544 in the two previous weeks; of these, 216 resulted from measles, 155 from whooping-cough, 44 from diphtheria, 35 from diarrhoea, 33 from scarlet fever, 23 from "fever" (principally enteric), but not one from small-pox. No death from any of these epidemic diseases was registered last week in Plymouth, Southampton, Hornsey, York, or in eight other smaller towns; the annual rates from these diseases, however, ranged upwards in the other towns to 4·0 in Birkenhead, 4·6 in Middlesbrough, 5·1 in Bolton, and 5·9 in Nottingham. The fatal cases of measles in the 76 towns, which had been 251 and 223 in the two previous weeks, further declined last week to 216; they caused the highest annual death-rates, 3·1 in Middlesbrough, 3·6 in Nottingham, 3·7 in Bolton, and 4·0 in Birkenhead. The 155 deaths from whooping-cough were fewer by 16 than the number in the previous week; they were proportionally most numerous in West Hartlepool, Nottingham, Salford, and Tottenham. Diphtheria showed the greatest fatality in Swansea, Rochdale, and Reading; diarrhoea in Middlesbrough; scarlet fever in Sheffield, and "fever" in Wigan. No case of small-pox has been under treatment in the Metropolitan Asylums Hospitals since the end of June last. The number of scarlet fever patients in these hospitals and in the London Fever Hospital, which had been 2686 and 2637 in the two previous weeks, had further declined to 2628 at the end of the week under notice; 361 new cases were, however, admitted during the week, against 352 and 298 in the two preceding weeks. The deaths referred to pneumonia and other diseases of the respiratory organs, in London, which had been 412 and 355 in the two previous weeks, further declined to 326 in the week under notice, but exceeded by 15 the corrected average number in the corresponding week of the five years 1902-06. The causes of 47, or 0·9 per cent., of the deaths registered during the week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Leeds, in Bristol, West Ham, Bradford, Newcastle-on-Tyne, and in 53 other of the 76 towns; the proportion of uncertified deaths, however, again showed considerable excess in Birmingham, Liverpool, Sunderland, South Shields, and Rochdale.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in eight of the principal Scotch towns, which had been equal to 19·4 and 20·2 per 1000 in the two preceding weeks, declined again to 20·0 in the week ending April 20th, but exceeded by 3·2 the mean rate during the same week in the 76 large English towns. The rates in the eight Scotch towns ranged from 10·6 and 15·8 in Paisley and Aberdeen to 22·2 in Glasgow and 25·6 in Leith. The 695 deaths in the eight towns were within five of the number returned in the previous week, and included 133 which were referred to the principal epidemic diseases, against numbers increasing steadily from 100 to 124 in the five preceding

weeks. These 133 deaths were equal to an annual rate of 3·8 per 1000, which exceeded by 2·2 per 1000 the rate from the principal epidemic diseases in the 76 English towns; they included 54 from whooping-cough, 42 from "fever," 17 from measles, 17 from diarrhoea, two from diphtheria, one from scarlet fever, but not one from small-pox. The 54 fatal cases of whooping-cough were within one of the high number in the previous week, and included 41 in Glasgow, six in Edinburgh, three in Aberdeen, and two in Dundee and in Greenock. The 42 deaths referred to "fever," showed a decline of seven from the number in the previous week, but included 21 in Glasgow, ten in Edinburgh, six in Leith, four in Greenock, and one in Dundee; 18 deaths were certified from cerebro-spinal meningitis in Glasgow, ten in Edinburgh, six in Leith, and two in Greenock. Of the 17 fatal cases of measles eight occurred in Glasgow, five in Leith, and four in Edinburgh. 12 deaths were attributed to diarrhoea in Glasgow, three in Edinburgh, and two in Dundee. The deaths in the eight towns referred to diseases of the respiratory organs, including pneumonia, which had been 109 and 118 in the two preceding weeks, declined to 103 in the week under notice, and were 37 below the number in the corresponding week of last year. The causes of 30, or 4·3 per cent., of the deaths registered in the eight towns during the week were not certified or not stated; in the 76 English towns the proportion of uncertified deaths did not exceed 0·9 per cent.

HEALTH OF DUBLIN.

The annual rate of mortality in Dublin, which had been equal to 28·3 and 26·6 per 1000 in the two preceding weeks, rose again to 27·1 in the week ending April 20th. During the first three weeks of the current quarter the death-rate in the city averaged 27·3 per 1000, the rates during the same period did not exceed 16·8 in London and 17·3 in Edinburgh. The 203 deaths of Dublin residents during the week under notice exceeded by four the number in the previous week, and included 18 which were referred to the principal epidemic diseases, against 15 and 19 in the two preceding weeks; of these, ten resulted from measles, seven from whooping-cough, one from diarrhoea, but not one either from small-pox, scarlet fever, diphtheria, or "fever." These 18 deaths were equal to an annual rate of 2·4 per 1000, the rate during the same week from the principal epidemic diseases being 1·4 in London and 3·5 in Edinburgh. The ten fatal cases of measles exceeded the number returned in any recent week; and the seven of whooping-cough corresponded with the number in the previous week. The 203 deaths from all causes included 34 of children under one year of age and 48 of persons aged upwards of 60 years, each of these numbers showing a decline from those returned in the previous week. Four inquest cases and two deaths from violence were registered; and 84, or 41·4 per cent., of the deaths occurred in public institutions. The causes of three, or 1·5 per cent., of the deaths in Dublin last week were not certified; the percentage of uncertified deaths during the week did not exceed 0·9 in London, while it was 8·4 in Edinburgh. The 170 deaths registered in Belfast during the week under notice included 27 referred to cerebro-spinal fever or cerebro-spinal meningitis.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

Fleet Surgeon Joseph Crowley has been promoted to the rank of Deputy Inspector-General of Hospitals and Fleets in His Majesty's Fleet (dated March 17th, 1907).

In accordance with the provisions of Her late Majesty's Order in Council of April 1st, 1881, Fleet Surgeon Harold Frederic Dale Stephens and Fleet Surgeon George Wilson have been placed on the Retired List at their own request.

The following appointments are notified:—Fleet Surgeon: G. A. Dreaper to the *Nelson*. Surgeon: R. F. MacMahon to the *Pembroke*.

ARMY MEDICAL SERVICE.

Lieutenant-Colonel Thomas F. MacNeeca, from Royal Army Medical Corps, to be Colonel, vice E. H. Fenn, O.I.E., retired (dated Feb. 16th, 1907). Lieutenant-Colonel William Babbie, V.O., O.M.G., from Royal Army Medical Corps, to be Colonel supernumerary to Establishment, on

appointment as Inspector of Medical Services (dated March 12th, 1907).

ROYAL ARMY MEDICAL CORPS.

Lieutenant-Colonel Reynolds P. Hetherington is placed on temporary half-pay on account of ill health (dated April 19th, 1907). Captain Richard E. G. Phillips retires, receiving a gratuity (dated April 24th, 1907). Lieutenant Winfrid K. Beaman is seconded under the provisions of Article 349, Royal Warrant (dated Jan. 28th, 1907).

Lieutenant-Colonel G. W. Brazier-Cragh, O.M.G., from Woolwich, has been posted to the Northern Command at Lichfield. Lieutenant-Colonel R. S. F. Henderson has been appointed to Netley Hospital, vice Lieutenant-Colonel G. E. Twiss.

INDIAN MEDICAL SERVICE.

The King has approved of the following promotions among officers of the Indian Medical Service: Lieutenants to be Captains (dated Jan. 30th, 1907): Hugh Basil Drake, Ernest Charles Hodgson, William Sim McGillivray, William Gillitt, William Frederick Brayne, Charles Harrison Barber, William Tarr, Merwan Sorab Irani, Hugh Watts, Ivor Davenport Jones, Walter Taylor Finlayson, Seymour Whitworth Jones, William Thomas McCowen, Hugh Ellis Stanger-Leathes, John Anderson, Edmund Arthur Roberts, Geoffrey Gratix Hirst, Michael Joseph Quirke, John Morgan Holmes, and Maurice Forbes White.

IMPERIAL YEOMANRY.

Oxfordshire (Queen's Own Oxfordshire Hussars): Surgeon-Lieutenant-Colonel H. P. Symonds is granted the honorary rank of Surgeon-Colonel (dated March 14th, 1907). Surgeon-Lieutenant Colonel and Honorary Surgeon-Colonel H. P. Symonds resigns his commission, with permission to retain his rank and to wear the prescribed uniform (dated March 15th, 1907).

VOLUNTEER CORPS.

Royal Garrison Artillery (Volunteers): 2nd Sussex: The undermentioned Surgeon-Lieutenant-Colonels are granted the honorary rank of Surgeon-Colonel: H. Colgate (dated Dec. 1st, 1906) and H. Haggood (dated Dec. 1st, 1906).

Rifles: 1st Volunteer Battalion the East Yorkshire Regiment: The undermentioned to be Surgeon-Lieutenants: Oswald Lucas Appleton (dated Feb. 9th, 1907); and Percy Roberts Ash (dated Feb. 19th, 1907). 1st Volunteer Battalion the Royal Scots Fusiliers: Surgeon-Lieutenant-Colonel W. Wilson is borne as supernumerary whilst holding the appointment of Brigade-Surgeon-Lieutenant-Colonel, Senior Medical Officer, Scottish Border Volunteer Infantry Brigade (dated March 13th, 1907). 2nd London Volunteer Rifle Corps: Henry Kay Ramsden (late Surgeon-Captain, 2nd Battalion, Royal Guernsey Militia Light Infantry) to be Surgeon-Captain (dated March 5th, 1907). 2nd (Renfrewshire) Volunteer Battalion, Princess Louise's (Argyll and Sutherland Highlanders): Surgeon-Lieutenant G. W. Coats resigns his commission (dated March 12th, 1907).

ROYAL ARMY MEDICAL CORPS (VOLUNTEERS).

Eastern Command: Maidstone Companies: William Henry Flint to be Lieutenant (dated March 18th, 1907). 2nd London Volunteer Infantry Brigade Bearer Company: William Bain to be Lieutenant (dated March 7th, 1907).

THE COLONIAL CONFERENCE.

The Colonial Conference, if it has not led to the establishment of an imperial council as a necessary step preliminary to the organisation of a plan of imperial defence, has nevertheless gone a considerable way in that direction. It has decided upon holding its meetings every four years and upon forming a new permanent consultative and informative body to act between the motherland and the colonies. The Prime Minister is in future to preside over the Conference. One question before the Colonial Conference has been that of the military defence of the Empire and the discussion which ranged over the military systems of Great Britain and various colonies.

UNIVERSAL MILITARY TRAINING.

A system of universal and uniform physical training and military drill has, it is announced, been already inaugurated in Canadian schools. Earl Roberts has strengthened the hands of the National Service League by the publication in book form of the various speeches and addresses he has felt constrained to make during the last 18 months upon our present unpreparedness for war and the way in which, as he has so strenuously advocated, it should be met and overcome.

Correspondence.

"Audi alteram partem."

THE USE OF ALCOHOLIC BEVERAGES.

To the Editors of THE LANCET.

SIRS,—In view of the fact that six out of eight letters on "The Use of Alcoholic Beverages," published in the two preceding numbers of your journal, have all insisted on the need for evidence to support the contentions of the 16 signatories to the manifesto, I had hoped that this week's issue would have contained letters from one or more of these gentlemen dealing specifically with this point. Instead, two additional letters have now brought the total to eight correspondents who have in this respect a like desire. While the one letter published by one of the authors of the manifesto disregards this central question, that has most obviously been the dominant one in the majority of his fellow practitioners' minds.

THE LANCET is a medical publication, published for, and read mainly by, medical men, though it has, as is well known, a wide circulation among the better educated individuals of the general public, yet it is as a technical paper that its policy has always been determined. Surely, therefore, the demand for evidence for any medical manifesto published in your columns has peculiar force and ought not to be disregarded. All reasonable medical men will sincerely regret any bigotry that has been shown to any of the signatories to the manifesto. But the serious evil that excessive drinking causes to the nation is some excuse, though no justification, for its existence; and, moreover, this bigotry of some abstainers is, of course, largely the inevitable result of a reaction against established prejudice on the part of those who are not abstainers. With neither of these feelings are medical men concerned. We are, or ought to be, interested directly with the medical and indirectly with the social aspects of the problem. And as we all have personal opinions on the matter and all, who have any practice at all, much experience also, we want carefully sifted scientific evidence to consider the reliability or the unreliability of the newer research work which has given its verdict so largely against alcohol. Such statements as the two published in to-day's issue that abstainers are often large meat-eaters and that alcohol has some food value are not calculated to reassure other medical men of the competence of those who would give us a re-statement of the old view of the subject. Eastern countries like Japan are both abstaining and largely non-meat-eating, as compared with Western countries that are both, and it is the dangerous disadvantages of alcohol, not its small food advantages, that evidence is needed upon. Many of us would be quite willing to modify our views, but as scientifically trained men we require definite data to affect us, and our social responsibilities are such that to feel otherwise would be criminal. As no competent medical man would deny that alcohol is on occasion of service in the treatment of disease, and that for this purpose the various beers, wines, and spirits on the market may have each their special value, the whole point of the manifesto turns on the one question—its value in health.

In my letter published in THE LANCET of April 13th I mentioned eight independent specific lines of evidence which have all tended to establish the belief that alcohol is in some degree harmful to health; other correspondents took up similar positions. Now suppose it can be established by *new* facts that these eight converging groups of studies are all fallacious, it has still further to be proved that alcohol is not socially injurious if we are to accept the position that the manifesto defines. For it is certain "moderate" drinking does lead ultimately in many individuals to "excessive" drinking, and this is admitted to be an evil. We are justified, therefore, in asking the signatories to supply us not only with evidence to confute research students on the eight points I have alluded to, but also to inquire what remedy they would propose to check the development of the craving in those by nature predisposed to its power before we as social and individual medical advisers can sanction its usage as a national beverage. It ought surely to be evident that scientific evidence and not personal

opinion must alone ultimately decide the issue, and I would respectfully ask of the signatories for direct data to be produced on the question which they themselves have voluntarily brought before the medical world.

I am, Sirs, yours faithfully,
Willesden Green, N.W., April 20th, 1907. J. LIONEL TAYLER.

To the Editors of THE LANCET.

SIRS,—It is refreshing to read the common sense of Mr. Edmund Owen on the subject of "temperance." Every word of his letter is fully justified by the remarks of other of your correspondents, particularly by that most sarcastic letter of Dr. J. W. Carr. Dr. Carr actually writes: "Many medical men who up to now have been endeavouring to inculcate temperance principles on their families and patients will doubtless in the future teach the necessity for moderate drinking." What, in the name of sobriety, is "temperance" but moderation in drinking? But this would make the above profound sentence if not meaningless then decidedly tautological. Mr. Owen says, with perfect truth, that "the rank and file of our profession are one and all in favour of temperance," and I for one claim, with Dr. Carr and Mr. Owen, to be a teacher of temperance to my family and patients, but I drink cider or a glass of claret with my meals and even occasionally a glass of whisky-and-water with a friend at night. Several correspondents have remarked that we medical men see more than any others the evil effects of intemperance. True; but, on the other hand, are not nine-tenths—nay, nineteen-twentieths—of our personal friends, of those whom we most respect and love, men who, like ourselves, use intoxicating beverages in moderation? If words mean anything this is true "temperance." Doubtless, abuse leads to disaster, in the case of intoxicants to terrible and widespread disaster, but to condemn entirely and universally the use of wine for this reason is headstrong and savours of fanaticism.

So the vegetarian urges the universal disuse of animal food because of the admitted evils resulting from excess of nitrogenous diet and because some find themselves better if they eat no meat. Or take another analogous case. Who but the medical man knows so well the dire results of sexual intemperance? But is total abstinence therefore the only true remedy? At various periods of the world's history there have been fanatics who have maintained that it is, but in this case everyone recognises that they *were* fanatics, or would Dr. Carr say that I cannot rightly claim to inculcate sexual temperance because I have a family of my own?

I am, Sirs, yours faithfully,
Bromsgrove, April 23rd, 1907. CAMERON KIDD.

To the Editors of THE LANCET.

SIRS,—I should like to know whether Mr. Edmund Owen and his co-signatories of the manifesto approve of the use that is being made of their names by "the trade"? Are they aware that a reprint of the manifesto with names attached is being distributed to customers in public houses? Do they know that a firm that pushes the sale of a certain stout has added a copy of the manifesto to one of its circulars which also contains a garbled and misleading extract from Sir Michael Foster? It is certain that the use of the manifesto in this way, which is, of course, what many of us expected, will tend seriously to increase the use of alcoholic beverages, any force that the last paragraph of the manifesto might possibly have with a few notwithstanding.

I am, Sirs, yours faithfully,
THOMAS RUSHBROOKE, M.A. Cantab., M.R.C.S. Eng.
Stamford Hill, N., April 24th, 1907.

To the Editors of THE LANCET.

SIRS,—Dr. Burns, the secretary of the London Temperance Hospital, judging from the tenour of his letter, appears to be swayed by the popular sentiment that a few eminent medical men with the capture of their names on his side will settle this vexed question, whereas it must be decided on the weight of evidence. Meantime it is certain that so long as the total abstinence party constitute themselves the sole judge and jury and advocate of their own cause no unbiased judgment can possibly be arrived at. Why, may I ask, should not this complex question be submitted to

some impartial tribunal, somewhat analogous to a Royal Commission, who could in a judicial spirit analyse and test the evidence which the teetotal party seem to think so convincing and conclusive. Take, for instance, the oft-repeated testimony of those insurance companies, who inform the world that between total abstinence and moderate drink the former is in favour of longevity, when it must be obvious that no company (unless indeed they employ detectives in plain clothes) can guarantee any of their general section as moderate consumers of alcohol. Further, much stress, as everybody knows, is placed upon alcoholic excess by alienists as a cause of insanity. What evidence is there, however, on the other hand, to prove that the judicious use of alcohol in many cases may not in the wear and tear of everyday life afford some ballast to the overwrought nervous system and prevent a total collapse? May it not act thus in advancing years when the natural pride and enthusiasm of life which affords a healthy stimulus to younger minds has vanished and no longer acts upon the aged and prosaïc? I ask what evidence is there to show that in these cases moderate stimulants may not ward off, or at least lessen the chances of, senile dementia? In a letter which appeared in the *Times* brimful of significance from the late Lord Grimthorpe, which I can corroborate from the observation of somewhat identical conditions, the following statement occurs which, although not scientific evidence, is possibly more trustworthy in some respects:—

The late Mr. Proctor the astronomer at one time took up teetotalism and preached it as an infallible dogma in knowledge. I warned him from my own experience, as he was a hard worker with his head, and he laughed at it. Within six weeks he recanted and told me I was right. I forget whether he published his recantation. I have known sundry other "brain workers" try the experiment and I have never known more than one who had not to recant.

Surely evidence of this kind is of moment.

I am, Sirs, yours faithfully,

Brighton, April 16th, 1907.

CLEMENT H. SERS.

To the Editors of THE LANCET.

SIRS,—Each one of us must be conscious of the gulf dividing the apologist for strong drink from the apostle of total abstinence in this one regard—namely, that the apostle, however narrowly intolerant, is at least impelled by an ideal and believes firmly in the ultimate usefulness of his cause. Can the same possibly be said for the apologist who encourages those around him to alcoholic habits, however harmless? How, in the face of the natural proclivity to intemperance, can medical men presume to recommend what they know to be productive of infinitely more harm than good? It is far less a question of abstinence than of common sense and I would ask if anyone can for a moment hold that the normally constituted and healthful individual would suffer from the immediate removal of all intoxicating liquors from the globe. There are those who pretend to believe that a nation may owe her supremacy in part to the influence of alcohol; who can even imagine a proof of this? But it is terribly easy to trace the misery consequent on strong drink. Let men be honest; strychnine is helpful and alcohol too in subduing pathological conditions, but for the strong man these are needless. I follow the fashion and add my delicate confession of being no stranger to wine, but of this I make no boast.—I am, Sirs, yours faithfully,

BOSWALL DODDS, M.D. Edin.

Starcross, Devonshire, April 21st, 1907.

To the Editors of THE LANCET.

SIRS,—Mr. Edmund Owen in his letter in THE LANCET of April 20th touches upon the most important point of the controversy to my thinking. He asserts that no sane person ever drinks alcohol and he would as soon think of drinking paraffin or naphtha. And yet as far as I can gather most of the so-called scientific investigations on the subject have been based upon the use of pure diluted or undiluted alcohol—that is to say, the experiments have been made with C_2H_5OH + or − H_2O and nothing more. To say that these experiments represent accurately the action of beer, wine, and spirits is, it seems to me, tantamount to saying that the action of a few grains of caffeine dissolved in distilled water is equal to that of a cup of tea. There is something else besides alcohol in

wines, beers, and even spirits, just as there is something else besides caffeine in a cup of tea.

I am, Sirs, yours faithfully,

CHEMIOUS.

April 23rd, 1907.

THE CONDITION OF THE BLOOD-VESSELS DURING SHOCK.

To the Editors of THE LANCET.

SIRS,—Professor Wenckebach's contribution in your issue of April 13th, as coming from an acknowledged and distinguished authority, is, to say the least of it, astonishing. He relates a case in which a full dose of digitalis produced an almost impalpable pulse, together with "well-filled," extremely hard, and wildly beating throbbing carotids," phenomena in which he seems to find something obscure. What else, one wonders, did he expect would occur? The effect of digitalis is to produce contraction of the arteries. The arteries are endowed with contractility in decreasing measure as we pass from the periphery to the centre. The radial is further from the centre than the carotid. The same influence which would cause the former to contract tightly, would therefore allow the latter to retain, substantially, its normal calibre. The pulse in the one would thus be almost imperceptible, while the increased pressure would cause the other to become "well filled, extremely hard, and wildly beating." The learned professor goes on to inquire "who will tell what the blood pressure has to be in the contracted radials at the wrist," and wishes to know if I am sure that it will be found high in that portion of the arterial system. In reply, I beg with all due humility to say that I have been always taught to believe that the pressure of a fluid in the "nozzle of a tube is certainly not less than the pressure in the tube itself. But what all this has to do with the condition of the blood-vessels in shock it is for me quite impossible to discover.

In your issue of March 23rd I invited Mr. J. D. Malcolm to point out any fallacies in one of the arguments by which the present view is sustained. He replied in your issue of March 30th with two statements. In your issue of April 13th I maintained that these, so far from exposing any fallacies, displayed, in the one case, a lack of mental perspective, and in the other, a physiological inexactitude. In your current issue Mr. Malcolm re-states his first proposition, and, in reply to my criticism of his second, while attributing to me opinions which I have never held and never expressed, he states that the "fallacy" resides in the fact that I failed to make myself clear. I do not therefore propose to continue the discussion.

I am, Sirs, yours faithfully,

London, W., April 20th, 1907.

LEONARD WILLIAMS.

THE SALUBRITY OF THE THAMES VALLEY.

To the Editors of THE LANCET.

SIRS,—The Thames Valley has for a long time borne a traditional reputation of being unhealthy, and several London specialists have been in the habit of advising their patients to avoid its supposed miasmatic influences. Like many other traditions, however, it can be demonstrated that this, too, rests on no solid foundation. Take one or two patent facts. No public school in England is more healthy than Eton, and that noble institution lies in the very heart of the Thames Valley. At some 50 feet above the level of the Thames and about a mile distant from Eton stands the little town of Slough, in the parish of Upton. As to the salubrity of this town let the medical officer of health, Mr. E. Weaver Adams, F.R.C.S., be called as witness. In his official report for 1906 he states that the death-rate in the town was only 10·2 per 1000, while the death-rate in 142 other small towns in England was 14·4 per 1000. And further, there were only 17 "notifiable cases" of illness amongst residents in Slough in the whole year (1906). This is a very remarkable record, and it certainly proves that the place does not deserve to bear an evil repute, though it be in the Thames Valley. It should be added that gravel, thoroughly well drained, is the predominant stratum of the district, and consequently the streets and roads become dry very rapidly after rain.

Lastly, if it be conceded that sunshine contributes greatly

to health I learn from an experienced meteorologist resident in Slough that the town enjoyed "bright sunshine" for nearly 15 hours a day in four of the spring and summer months in 1906. Could many of the usual health resorts show a better record? I am, Sirs, yours faithfully,

AN OCTOGENARIAN RESIDENT IN THE THAMES VALLEY.
April 22nd, 1907.

Our venerable correspondent has right on his side. The Thames Valley is often spoken of as unhealthy by the public, though we were not aware that this view had medical endorsement. Slough may suffer from its name, which is associated in the public mind with "bog" and "morass." The proper name of Slough is Upton; it lies high above the Thames on a gravel soil, and is a remarkably healthy town.—ED. L.

SOME TURKISH LAZARETS

AND OTHER SANITARY INSTITUTIONS IN THE NEAR EAST.

BY THE BRITISH DELEGATE ON THE CONSTANTINOPLE BOARD OF HEALTH.

(With Reproductions of Photographs taken by the Author.)

I.

Sketch of the General Scheme of Maritime and Frontier Sanitary Defence of the Turkish Empire.—The History of the Camaran Lazaret.—The Villages on Camaran Island.—The Numbers of Pilgrims Interned and the Nature of the Measures Applied.

BEFORE proceeding to describe the sanitary stations visited by the Commission, it will be useful to give a brief account of the entire system of maritime and frontier sanitary defence in the Turkish Empire. The Constantinople Board of Health has under its management a series of lazarets, a small number of simple disinfecting stations, and a large number of sanitary offices. The lazarets, of which there are nine, are large and complex establishments, in which quarantines, disinfection, and other sanitary measures are applied. Their names and positions are indicated in the

Small sketch map of the Turkish Empire, showing position of the lazarets and disinfecting stations, existing and proposed.

accompanying sketch map. There are two in the Black Sea—Sinope and Kavak (at the entrance of the Bosphorus); three in the Mediterranean—Clazomene, near to Smyrna, Beirût, and Tripoli on the African coast; two in the Red Sea—Abu-Saad, near to Jeddah, and Camaran; one, that of Basra, in the Persian Gulf; and one, that of Khanikin, near the Turco-Persian frontier.

There are two disinfecting stations in existence, those of Jaffa and Rhodes, and it is proposed to construct five others, respectively at Trebizond in the Black Sea, Salonica in the Ægean, Volona on the Adriatic coast, Yanbo in the Red Sea, and at Kizil-Dizé on the Turco-Persian frontier. At these stations medical visit, disinfection, and even a period of observation not exceeding 24 hours are applied. They are of great use to navigation, as in their absence ships would have to go to one of the lazarets to undergo these

measures, and this often involves the ship making a long detour, with corresponding loss of time and money.

The sanitary offices are 135 in number, scattered along the coasts and land frontiers of the whole empire. In 44 there are medical officers, and here ships can undergo "medical visit"; in 91 there is no medical officer, and at these ports ships merely undergo the ordinary sanitary interrogation and pay their sanitary dues.

The lazaret of Camaran was the first and largest of those visited by the Inspection Commission. It is probably one of the largest and most important sanitary institutions in the world, since it is destined to receive the majority of Moslem pilgrims coming to the Hedjaz from countries situated beyond the Straits of Bab-el-Mandeb.

The island of Camaran upon which the lazaret is built is situated off the coast of the Arabian province of the Yemen, about 15° north of the equator, at a distance of some 40 sea-miles to the north-west of Hodeidah, four to the west of Salif, and 20 to the south-west of Lohela. It is separated from the mainland by a channel, which in its narrowest part is not more than one and a quarter sea-miles broad. It is a coral island, some 18 kilometres long from north to south, and from three to eight kilometres wide from east to west. Its surface has all the characters of the desert; flat in some parts, undulating in others, and rising in some to a height of several metres above sea-level.

The history of the steps which led to the choice of this island for the quarantining of pilgrims from the east on their way to Mecca and Medina is of interest. The earliest proposal for the creation of an institution of this nature was made by the International Sanitary Conference held in Constantinople in 1866. That conference decided: (1) that a sanitary establishment should be created near the entrance of the Red Sea; (2) that the international character of this establishment was a *sine qua non*, the form to be given to the institution and to the measures to be applied there being left to the Governments interested, and it being suggested that the lazaret should be placed under the direction of either Turkey or Egypt, but under the control and with the assistance of Europe; and (3) that the measures applied there would be based on an international regulation and executed by an authority placed under the control of the Governments interested. When the next International Conference met in Vienna in 1874 these decisions were incorporated in the convention which followed; but it was not until some seven years later that steps were taken to give effect to them. In the meantime two Commissions had been sent by the Turkish Government to inspect the coasts and islands in and near the southern portions of the Red Sea, with a view to selecting a suitable site for the new lazaret. The first explored, in 1867, a large number of possible sites on the Red Sea shores of Arabia, and finally decided to recommend the island of Camaran as offering on the whole the greatest number of advantages. The second, sent three years later, with instructions to examine the coasts between Perim and Mokalla—that is to say, the southern coasts of Arabia outside the Straits of Bab-el-Mandeb—reported in favour of Sheikh-Said, a small bay at the very entrance to the Red Sea, and just opposite to Perim.

In 1881, when cholera broke out again at Mecca, the Constantinople Board of Health decided to improvise at Camaran a small lazaret where the inhabitants of the Yemen returning from the pilgrimage were to be quarantined before proceeding to their homes. This measure appearing to have given good results the board decided in the following year to build a permanent and large lazaret, where all arrivals from India would be quarantined before going on to the Hedjaz. It took another two years to bring the lazaret into being, and that institution was both more primitive than the present one and occupied a site more to the south. The present establishment may almost be said to date from some ten years back, when the large sum of £T.81,500¹ was voted for the "refection" of the Camaran lazaret. In the course of two or three years most of this money was spent, and the buildings and installations to be described in these articles were thus brought into existence.

To return to the description of the island and lazaret. The latter is built on the east coast of the island, facing the mainland. There is here a bay, which cuts into the island for a distance of about 1000 yards and is about 600 yards wide. On the southern shores of this bay is the large village of Camaran; on its northern shores are the administrative

¹ A Turkish pound (ET.) is equivalent to about 18s.

and other so-called "central" buildings of the lazaret, the camps for the pilgrims forming an irregular line, some four and a half kilometres long from south to north, and running more or less parallel with the eastern shores of the island. The village of Camaran is said to contain about 5000 inhabitants. It is not the only one on the island; there are indeed five others, called respectively Yemen, Fourra, Mekrem, Sella, and Seifaf; but none of them are of any size, the largest containing only 35 and the smallest only five houses. These villages are occupied by an Arab population, mostly employed in fishing for, or trading in, pearls, which are found in considerable numbers in this region.

While most of the island is desert there are several oases where palm-trees of various kinds flourish. In all parts of the island, wherever the least depression in the ground allows the sand to retain some humidity there is an abundant and very characteristic desert flora. A great variety of shells and coral is found here and the bird life is remarkably varied and interesting. The climate is pleasant in winter but the heat in summer is said to be very great.

The lazaret of Camaran is supposed to be open only for the six lunar months of the Moslem Pilgrimage—viz., those of Redjeb, Shaban, Ramazan, Sheval, Zilcadé, and Zilhidge. As the Moslem year is composed of only 12 lunar months it is shorter by some 11 days than the true solar year. Hence any Moslem date is about 11 days earlier each successive year. It follows that the pilgrimage season may fall in spring, summer, autumn, or winter. At the present time it falls mainly in autumn and winter; the last of Redjeb last year fell on August 21st, and the three days of Kurban Bairam, in which the fêtes at Mecca culminate, were in the latter half of January, 1907. During the remaining half of the year the staff of the lazaret is reduced to the smallest number compatible with the surveillance and upkeep of the various buildings and installations. All ships carrying a number of pilgrims exceeding 5 per cent. of their net tonnage should go to Camaran; those with less may go to the much smaller lazaret of Abu-Saad, near to Jeddah. As a matter of fact, most, if not all, ships from the north, even if they carry more than 5 per cent. of pilgrims, go to the Abu-Saad lazaret. The total number of pilgrims quarantined at Camaran in the last 25 years is shown in the following table. It will be seen that the number varies greatly from year to year; thus in 1882 there were only 9067; in 1903-04, and again in 1905-06, the total exceeded 32,000.

Table showing the Total Number of Pilgrims Quarantined at Camaran in the last 25 Pilgrim Seasons.

For many years past all pilgrims from India have been subjected to ten days' quarantine at Camaran. Those from an infected port in any other country, whether disease has broken out on the ship or not, undergo the same period of quarantine. Ships from the Dutch Indies, Ceylon, Straits Settlements, Persian Gulf, and some other countries are regarded as "suspect" and do only five days' quarantine. The other measures applied consist of a thorough disinfection of the pilgrims' clothes and baggage, a douche bath for the pilgrims themselves, and a cleansing and disinfection of the ship and crew. The pilgrims pass their quarantine in camps, to be described later; while there they undergo a medical inspection twice a day in order that any case, or suspected case, of cholera, plague, or other disease may be at once

detected and isolated. If such a case occurs the patient is removed to hospital; the rest of the pilgrims in the infected camp do 12 days' quarantine for the first case, and ten for any subsequent cases, before they are allowed to leave the lazaret and proceed to the Hedjaz. They are thoroughly disinfected before leaving and no pilgrim is allowed to depart unless the medical officers of the lazaret are satisfied that he is free from infection.

(To be continued.)

THE MILK-SUPPLY OF LONDON: SOME PERSONAL OBSERVATIONS UPON ITS RAILWAY TRANSPORT.

(FROM A CORRESPONDENT.)

II.¹

The Milk Can.—The Milk Van.—The Milk Train.—The Regulations in Respect of Milk Transport.—The Delivery of Milk at Paddington Station.

MILK reaches the metropolis either by special milk trains or by ordinary goods and passenger trains, but in all cases the can in which the milk is contained is of the familiar shape. It is universally employed and so becomes an important article in milk transportation. The milk can, which is frequently and wrongly termed a churn, is usually of about the same size and the same shape on all our home railroads running into London. It is about two and one half feet in height, round in shape, with a broad base gradually narrowing towards the top, where it expands again into a broad brim. It has a capacity varying from 14 to 17 gallons. It is provided with a closely fitting lid with a fastening arrangement at the side, and in the majority of cases there is a raised portion in the centre of the lid containing holes for ventilation. The shape of the can has its reasons; it can be easily cleaned and handled with comparative facility, its round shape, expanding below, permitting of it being moved without difficulty by rotation on the edge of its base. On the whole the construction of railway milk cans appears to be sufficiently satisfactory, but there is one grave fault in regard to their use which has, I believe, been made the subject of many strictures already, but with little or no effect. By far the greater part of the milk sent by rail is carried in unfastened cans. Indeed, it would be no great exaggeration, I think, to state, that not more than one can in 1000 of all that are brought into London by the railroads is locked or sealed. There are arrangements for locking the cans but they are habitually overlooked. That it would be better for the general public if cans were locked while being conveyed by rail or while deposited on the platforms of stations is obvious. Sealing or locking of milk cans should surely be made compulsory as a means of protection to the consigner and the consignee. At present the bulk of the milk which reaches London may be tampered with in transit, dirt may obtain entrance to the can on account of the lid being opened, dishonest persons may abstract the milk with any beastly sort of vessel, and may replace the stolen milk with any beastly sort of water. I have seen on more than one London railway station platform milk cans with lids unfastened and partly opened, allowing free ingress to the various kinds of dirt which must abound in London stations. I am simply unable to understand why both consigner and consignee do not agree, the one never to send, the other never to accept, any cans that can be thus tampered with in transit, and I am of opinion that if those peculiarly interested cannot take such an obvious step in self-protection that our sanitary authorities should compel them to take it for the protection of the public. There is an impression that railway companies are opposed to cans being sealed while in their charge, but I have conversed with many of the officials and as far as I have been able to ascertain the impression is altogether erroneous. The regulations in vogue with respect to milk transport are practically the same for all the railroad companies which enter London. Each can must have the number of imperial gallons it is capable of containing marked upon it and the inside of each can must be marked to indicate the space occupied by eight gallons and by each additional gallon.

¹ No. I. was published in THE LANCET of April 27th, 1907, p. 1116.

In the case of the few "sealed" cans, instead of the inside of the can being marked each can must bear its "tare" conspicuously stamped thereon outside. The officials of the railway company have the power to open any cans during transit and, if necessary, to detain the same for a reasonable time, in order to ascertain if the quantity of milk therein agrees with the quantity declared; but this is a reasonable precaution for them to insist upon. We may be sure that such inspection would only be put into practice where there were grounds for suspicion that the company was being defrauded, for neither the farmer, the purveyor, nor the public would tolerate the milk-supply of London being subjected to any system analogous to the proceedings of an American Custom House.

The Great Western Railway is the largest carrier of milk to London and the first station which I visited when I made up my mind to gather together my random ideas as to milk transportation was Paddington. Although milk is conveyed to the metropolis from almost all the districts over which the line has running powers, the greater part of it is brought from localities comparatively near to London, from Wiltshire, from Buckinghamshire, and from Berkshire. For the transport of milk the Great Western Railway employs special trains and passenger trains, but by far the greater part of the milk is carried in special trains. Three of these special trains are at the present time being run during the 24 hours, two of which arrive in London in the early hours of the morning, while one arrives about 10 A.M. I awaited the arrival of one of the early morning trains. It consisted of 28 milk vans, each van carrying 30 cans, so that the total cargo of milk, allowing 16 gallons to a can, would be 13,440 gallons. If the other two milk trains carried an equal quantity, the amount of milk brought into Paddington daily by special trains would be 40,320 gallons. The vans in common use are of strong construction, about 20 feet in length, 7½ feet in height, and 9 feet in width. Each is provided with open-boarded sides permitting of a through current of air, incidentally admitting the rain. A new type of milk van has been introduced by this railway recently. It is much larger; the sides are close boarded for a height of 2½ feet with louvres above. The close boarding and louvres arrangement excludes wet but admits air. The floor boards of the vans are covered with rock asphalt, which slopes towards a gutter in the middle so that the floors can be easily washed. As far as this railway is concerned, the facilities for transport of milk are consequently such that it should travel in a sanitary state. The special milk trains run at a fair rate of speed from the more outlying districts as far as Reading picking up milk on the way, and from Reading to Paddington the journey is made at express speed. The consequence is that, the distances to be traversed being comparatively small, the milk trains of the Great Western Railway are, for the most part, never long enough on the journey to allow chemical changes in the milk to be produced, while the construction of the milk vans, and especially of the new ones, seems to be well designed to assist in the preservation of the milk in a sweet condition.

But little milk is carried by passenger trains on the Great Western railway compared with the amount that is carried by special trains; none the less the amount of milk conveyed during the year by this means is considerable, and, of course, some of the milk thus transported has to travel long distances. The conditions in which milk is carried by passenger trains is at all times more or less insanitary, and when it is transported for long distances this evil is greatly aggravated. The luggage van in which the cans are placed is not infrequently full of a miscellaneous cargo, some of which may be exactly the sort to promote the tainting of milk, the ventilation is inadequate, the temperature in hot weather will be excessive, neither floor nor walls of such a luggage van will be subjected to any special process of scouring—in short, we have here all the factors calculated to produce chemical changes in the milk. I saw at Paddington station no particular example of milk being conveyed in a van that was obviously in an unfit state, but as all the milk conveyed in these vans appeared to be in unsealed or unlocked cans it is certain that any opportunities of selling offered by the method of transport would have a full chance of becoming effective. I saw many cans full of milk with their lids partly opened, and of all the cans that I observed I did not see one which was sealed or locked.

The Great Western Railway has a special platform for the unloading of milk, alongside of which come the dealers with

their vans for the purpose of taking it away for distribution. On this platform I saw, regardless of the enormous probabilities offered by the environments, cans freely opened and milk decanted. It is impossible to imagine a more unsuitable place for such a proceeding. I may mention that this never took place when any of the Aylesbury Dairy Company's milk was being shifted, while if I refrain from mentioning the offenders by name it is because I do not know if such practices are accidental or habitual. I was informed both that they often happened and that they never happened, and I have not visited this platform to meet the train in question more than once. Perhaps some of your readers may be able to supply the answer.

(To be continued.)

THE ORGANISATION OF THE MEDICAL PROFESSION IN FRANCE.

(FROM OUR SPECIAL COMMISSIONER.)

(Concluded from p. 913.)

The Maintenance of Discipline.—Penal Sanctions Conferred by the Tribunals and Medical Men Fined for Breaking their Medical Union Rules.

THE Concours Médical, it has been seen, has served as a parent or a forcing ground for the birth and growth of medical unions in France. To-day the organ of this association of medical men recalls criticisms which it made in 1901 and which it maintains apply with equal force to the present situation. It complained then, as it does to-day, that as the medical unions or syndicates grew in number they became weaker in cohesion and in discipline. It was therefore urged that instead of each medical union having its own rules, which were often imperfect and insufficient, all the unions should have the same rules. These rules should impose duties side by side with the rights which medical men sought to acquire. Again, a central authority should be able to prevent the overlapping of local unions and to establish geographical demarcations so that they should not trespass on each other's domains. Small unions readily followed this advice, notably at Noyon, Saumur, and Château-Thierry. With larger unions it was more difficult. In 1901 the Versailles medical union had already been in existence 15 years. It was a big cumbersome society, stretching over districts that had totally different interests, and the situation was further complicated by the proximity of Paris. It was soon found that a number of medical practitioners had joined with the hope of obtaining as many advantages as possible but with no idea of themselves doing anything whatever for the cause further than the doing out of a small subscription. It did not dawn upon them that they were no longer to endeavour to pay court to the patients of other practitioners, that the object of union was to prevent unfair or unprofessional competition. The fact that a good many members of the union had not entered into the true spirit of union caused unpleasant feelings, suspicion, and hesitation to arise.

Such seeds of disruption had to be extirpated and this with no uncertain, faltering hand. But in France, as in England, the question must be:—How is a member of a medical union to be compelled to fulfil his promises? After a lengthy study of all conceivable ways and means the council of the Federation of the Medical Unions of France came to conclusions of such importance and of such practical interest to the medical profession in all parts of the world that it is worth while to translate the actual text:—

1. In our opinion members of medical unions should represent the *élite* of the profession; they should be medical practitioners who are deeply convinced of the necessity of maintaining the dignity and solidarity of the profession.
2. If they are grouped in insufficiently small districts for each of these regions to have identical interests, the problems daily arising affecting the medical profession may be settled in a uniform manner. Once such a settlement has been attained, when the agreement has been duly accepted and voted upon, it constitutes a code, and if the articles of this code are not observed and there is no sufficient excuse given, a fault, a misdemeanour, has been committed which exposes the delinquent to a penalty, just as in the case. In regard to any other breach of a contract freely made. Then as the guarantee in regard to the damage done to the group or the members who are injuriously affected is readily appreciated by the members of the unions of the entire region, the members are much better able to judge such a matter than the ordinary tribunals, for these latter in such questions are not

1 See THE LANCET of March 30th, 1907, p. 911, and also of July 15th, 1895, p. 214.

at all competent. The rules of the medical union should anticipate as far as possible the nature of the delinquencies the members may commit. Thus a member when he gives his signature should be fully warned as to the nature of his rights, his duties, the obligations which he contracts to fulfil, the benefits he may hope to obtain, and the penalties to which he exposes himself.

Now this latter clause introduces an important punitive proposal. The principle is that if a person joins a union formed to promote a certain line of action and fails to carry out his undertaking towards it he injures and causes material damage to his colleagues. Therefore, he ought to be condemned for the breach of contract to the payment of damages. But if he were sued before an ordinary court the tribunal, being ignorant of the position of the medical profession and utterly unable to understand the professional interests at stake, would not know how to assess such damages. Therefore the medical union itself must decide what damages shall be paid.

This method of dealing with the question of discipline was adopted by the medical union of the Versailles *arrondissement* district. Each member of the union was called upon to sign a contract, by which he promised to pay a fine of not less than 16s. and not more than 240 if he broke the laws of the union. Of course, there was a great outcry. Such a drastic measure, it was said, would cause many medical men to leave the union; but the answer was given that those who were not thoroughly in earnest had better be outside the union. Then the question was asked, What would happen to a medical man whose practice was on the frontier line of two different unions? The answer was that he must obey the laws of the union in which his patient lived, and if his patients lived in the districts of two different unions then he must conform to the rules of each union when practising on its territory. Of course, this latter difficulty will become insignificant as the various unions adopt similar rules. Those adopted by the Versailles union are likely to serve as a model. The following are some of the more interesting clauses:—

Article VII. deals with the duties and obligations of members and these may be summed up by saying that the duty of the member consists in conforming strictly with the decisions of his union, notably with regard to questions relating to:—

1. Deontology.
2. The prohibition of all acts of illicit competition by means of intrigue, by the solicitation of patients, the abuse of colleagues, the reduction of fees, the forming of political or religious societies established to promote a personal professional interest, &c.
3. To assist spontaneously all fellow members who are in any way menaced or injured.

Again and again the objection was raised that these principles were admirable but that there was no guarantee that they would be applied. Indeed, it was found that some of the best and most honourable members of the profession would not join the medical union. When questioned they replied that it was precisely because they thoroughly approved the principles of the union that they did not join. If they joined they would scrupulously and strictly carry out its rules and regulations; but as there was no guarantee that all the other members of the union would be equally faithful to their principles those who really obeyed the rules would soon find themselves at a serious disadvantage. If, however, an effective guarantee could be given that those who did not keep their pledge would be punished with severity sufficient to render infractions unlikely and of rare occurrence then the best elements of the profession would join readily. Thus it was that at a meeting of the Medical Union of the Versailles District the 50 medical practitioners who were present voted unanimously in favour of the following rules:—

Article IX.—1. The sanctions applied in case the statutes or rules have been broken are only valid when voted by secret ballot at a general assembly and by the relative majority of the members present, and this only after the committee has investigated the matter, heard the parties concerned, and read a written report on the subject. The verdict may be pronounced in default, if the presumed delinquent has been summoned by registered letters to appear first before the committee of inquiry and then before the general assembly, and does not either attend or send a satisfactory explanation.

2. All penalties imposed in default may be challenged before a general assembly within a period of three months of their notification made by a ballot or a registered letter.

3. These penalties are: a warning, a reprimand, a fine of from 16s. to £40, and expulsion, which may be accompanied by a fine. The general assembly shall further decide whether there is just cause to take damages in case the fine shall not suffice to repair the injury done to the Medical Union. It is the general assembly that inflicts the two last-mentioned penalties, fine or expulsion, as also the taking of legal action, and the general assembly must for this purpose consist of at

least two-thirds of the members of the union; then the penalties or legal prosecution can only be inflicted if two-thirds of those present vote in favour of such a course.

4. Unless it is otherwise decided by the general assembly, all inflictions of penalties shall be inscribed in the minute book. They shall receive the usual publicity and the interested party shall not, in regard to such publicity, be able to take any action in law to recover damages from the Medical Union.

5. The fact that a member is expelled from the union does not exempt him from his responsibilities and from the payments or penalties to which he was previously liable.

Seeing the very great importance that the meetings of the general assembly should, in such circumstances, be well attended there is a special rule on this subject. It states that there shall be each year at least two obligatory general assemblies: one of these shall be followed by a banquet and at the other the election of officers and the payment of subscriptions shall take place. Every member who cannot attend must send a written excuse and pay a fine of 1 franc. If he fails to do this then he must pay a fine of 5 francs. Of course, exceptions are made in case of serious illness or other imperative cause of absence. But when there is a disciplinary assembly—that is to say, when an important verdict has to be rendered for or against a member of the union—then those members who fail to attend without sufficient excuse may be fined as much as 20 francs, or 16s.

It will be seen by these rules that the duties of a member of the Versailles Medical Union are treated very seriously and that membership does really involve a grave responsibility. But all this would have been of comparatively little importance if the rules of the medical union had not received a legal sanction. A case, however, did occur where a member of the medical union repudiated his obligations and was consequently summoned before the civil tribunal of Bourgoins. Here and in response to the eloquent pleading of his counsel, Maître Gatineau, the court held that the medical union was justified and that its members must fulfil all the conditions to which they had attached their signatures. This verdict gave new life to the medical unions and in many parts of France their rules were revised with a view to their enforcement if necessary before the law courts. This was notably the case with the Federation of the Medical Unions of the Department of the Nord, of the Pas-de-Calais, of the Jura, the Deux-Sèvres, the Creuse, and the Vendée, and also in the creation of a new union at Lorient.

In England this example might be of considerable value, for the difficulties and the problems at issue are almost identical. In France, as in England, it is the want of solidarity that constitutes the weakness of the movement. A medical practitioner may or, if he prefers, he may not belong to the local union of his profession. If he does join he may or he may not carry out the rules to which he has given his assent; the acceptance of the rules are not so arranged as to involve the signing a contract which it would be illegal to break? Undoubtedly one of the most effective weapons against a member of the profession who acts in an unworthy manner is some form of unfavourable publicity. In France a claim for damages would not hold if the plaintiff had on joining the medical union signed his acceptance of a set of rules which stipulated, among other things, that publicity should be given to any verdict pronounced against him by the medical union. There is assuredly something to be done by converting certain reprehensible acts into breaches, not merely of medical etiquette or of medical ethics, but of contracts which have been formally entered into before witnesses; the action of the French court is therefore very suggestive.

It is also interesting to note how the French medical unions propose to deal with young practitioners newly arrived in a district and with others who refuse to join the local medical union. Here is a set of rules:—

Article I.—Whenever a new colleague arrives and installs himself within the zone of the medical union his arrival shall be notified to the secretary by his nearest neighbour, who shall at the same time suggest what, in his opinion, would be the best means of inducing the newcomer to join the medical union. The syndic of the region will then receive a mandate instructing him to call upon the newcomer and act according to the advice received; he will endeavour to demonstrate the services the medical union can render to the newcomer and at the same time to warn him as to the faults he might commit.

So long as he has not clearly stated whether or not he will join the union and has not knowingly done any act of hostile competition against the union, the new colleague shall be treated by his rivals with the same consideration as if he was a member of the medical union.

Article II.—The same attitude as that laid down in paragraph 2 in the above article shall be adopted towards every medical practitioner who, though remaining outside the medical union, shall behave in an absolutely correct manner from a professional point of view. Also

endeavours should be made to obtain the aid and advice of such practitioners in all matters of general interest and thus seek to persuade them to join the union.

Article III.—When a medical practitioner who has been installed in the locality for two months, who has not during that time called on his neighbouring colleagues, has, after being fully informed of all the details, refused to our delegate to join our union, and is practising in competition instead of as a member of our combination, the members of the union shall reduce their professional relations with him to the strict minimum imposed by considerations of humanity and of the interests of the sick. None of us should consent to help him, to act in consultation with him, or to collaborate with him habitually. When yielding in a matter of urgency or through a sentiment of humanity it shall be clearly indicated that this is only done in response to an appeal made by the patient and that the exceptional collaboration which the patient may have made us undergo is limited absolutely to what is deontologically correct.

Further, as against the medical practitioner such as we are now dealing with, who is a bad colleague, members of the union may be liberated by a vote of the general assembly from all the consideration and from all obligations which we observe towards those who place professional dignity before commercial competition.

Such are some of the rules and the principles which govern the medical unions of France. As a result the medical practitioners have secured several solid advantages and the whole tone of the profession has been raised. The tendency to introduce in medical practice the methods of competition which prevail among petty tradesmen has been kept at bay, and the principle that science has a higher purpose than mere money-making has on several occasions been successfully vindicated.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

Night Shifts in Mills.

As may be known beyond the limits of the district, there has been of late a "boom" in certain branches of manufacture. With the view of metaphorically making hay while the sun shines some of the mills have been running through the night as well as through the day. How far it is for the health and well-being of those engaged in this night work is a matter that need not be considered at present but as a general rule it is not advisable to try to reverse the order of nature, and it should only be attempted when necessity urges. Whether the necessity for making money during the whole 24 hours is sufficiently urgent to justify the attempt is a matter that must be left to those interested to decide but there is another point of view brought forward by a contributor to one of the local papers that is worthy of attention. The writer asks if the pollution of the air by the smoke from the mills is to be allowed to go on during the night as well as the day. He thinks the physique of the working classes in our large towns is already low enough and should not be further lowered because some manufacturers are not content with running their mills by day. There will be no anxiety to keep down the production of black smoke when daylight is gone, but every incentive to careless and wasteful stoking. Night inspectors will have to be appointed and the expense will be borne by oppressed ratepayers who want neither smoke nor inspectors. It is rather hard that the 12 hours usually free from manufacturing smoke should be polluted like the rest of the 24, so that no chance is given for the unfortunate residents to breathe moderately pure air even at night.

Bread-making.

All are interested in bread and, as under modern conditions it is impossible that any but a small fraction of that used by the public can be "home-made," it is satisfactory to know that efforts are being made by bakers themselves to improve the art of bread-making. The Manchester, Salford, and District Master Bakers' Association is holding its fourth biennial northern counties exhibition in St. James's Hall in Manchester. In his opening address the chairman, Mr. Hicks, referred to the classes at the School of Technology for the teaching of scientific baking and confectionery and urged that the bakers should take more interest in the work of those classes. He said that within the last dozen years the whole process of bread-making had been revolutionised and thousands of pounds spent in remodelling bakeries and in providing technical instruction. He boldly claimed that the bread supplied to the public at the present day was absolutely pure. This is, no doubt, true with regard to the best firms, but, as one of the speakers at the opening said, it is only within the last few years that bread-making has been put on a really

scientific basis. All this is encouraging and consolatory, but very many years have not passed since the Manchester and Salford Sanitary Association made a report on the Manchester bakeries that was not only alarming but sickening. The underground bakeries, in which half-clothed, consumptive men sweated and coughed and spat through the long hours of night work in filthy, stuffy, ill-ventilated work-places, are now practically done away—for which all concerned cannot be too thankful—but as there are degrees of excellence as to appliances and as to the sanitary conditions under which the work of the bakery is carried on, so there may be a falling back in some cases, and in no occupation is thorough inspection more necessary than in the business of the bakery. Many of the most important firms from different parts of the country exhibit various kinds of flour, so that taste and fancy may be both stimulated and satisfied. It should be mentioned again that the equipment at the Manchester Municipal School of Technology for the teaching of bread-making and confectionery is very fine and complete. The classes are well attended by the students in bread-making, of whom at present there are 78, and at the same time there are 35 who are studying confectionery. The work done is said to be most excellent.

Clerks and Ill-health.

In a lecture at the Manchester Health Society meeting held recently Dr. A. C. Magian drew rather a sombre picture of the health of that large section of the Manchester population, the warehousemen and clerks. He says that nervous disease is greatly on the increase from the constant strain of figure work and the uncertainty as to improving their position or even maintaining it. Foul air and gas fumes are common factors in causing the debility of the desk-workers. Then they get into the habit of sucking ink, sucking and biting pencils, and licking stamps and envelopes, all more or less injurious. Food poisoning is becoming quite common; meals are neglected and irregular, consisting generally of "rubbish and a cigarette." Dr. Magian thinks it would be a good thing if the morning trams to the city were abolished, for some young fellows will not walk or take any healthy exercise. Of course, there are exceptions, but still the picture is widely applicable and is too true. What a boon some physical training and camp drill would be to these pallid, weakly, young men.

April 23rd.

WALES AND WESTERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENTS.)

Medical Inspection of School Children.

THE Pontypridd Education Committee was one of the first to realise the importance of obtaining the services of a medical officer, and very soon after the schools in the town came under control the committee appointed the medical officer of health of the town (Mr. Howard Davies) medical officer to the committee. Since his appointment Mr. Davies has carried out systematic inspections and has made valuable reports upon the eyesight of the school children. At the last meeting of the committee it was decided that he should be instructed to visit every department at least once a quarter and to report upon the sanitary condition of the schools and upon the general health of the children.

Bristol Workhouse Infirmary.

The provision of adequate infirmary accommodation in connexion with the two Bristol workhouses has been under consideration of the board of guardians for nearly ten years. Everyone seems to agree that the wooden huts which are in use at the Eastville Workhouse should be replaced by more permanent and less inflammable buildings, but differences of opinion are at once manifested when definite schemes are propounded. Plans for an entirely new building and proposals for a re-arrangement and extension of existing buildings have from time to time been considered by the board, but for various reasons they have all been rejected. The Local Government Board has now called the attention of the board of guardians to the very unsatisfactory position presented by the inactivity of the latter body. It is probable, therefore, that steps will be taken to put an end to conditions that are not very creditable in a town of the importance of Bristol. The guardians have decided to

appoint a consulting medical officer for the two infirmaries, there being at present a resident medical officer in each infirmary.

The Teaching of Horticulture in Rural Districts.

The Monmouthshire Education Committee has decided that horticulture shall be taught in the public elementary schools in the rural districts of the county. The question of adopting the same course is under consideration by a special committee of the Somerset Education Committee.

Formaldehyde in Milk.

Additional inspectors have recently been employed by the Cardiff health committee in connexion with the milk trade, and the appearance of delinquent milk vendors before the local justices would seem to justify these appointments. In one instance in which formaldehyde was found in considerable quantities in the milk supplied to the infirmary the stipendiary magistrate imposed the maximum penalty of £50 and allowed 10 guineas costs to the corporation.

The Freedom of Falmouth for Sir Joseph Fayrer.

Sir Joseph Fayrer has informed the Falmouth town council that it will afford him great pleasure to accept the offer of the council to present the freedom of the borough to him. The date fixed for the ceremony is August 3rd, when Falmouth will also entertain several members of the British Medical Association.

Winsley Sanatorium.

At a recent meeting of the house committee of the Winsley Sanatorium it was stated that by the new rules certain beds could be allocated to persons residing within the counties of Somerset, Gloucester, and Wilts, on payment of 35s. per week, and persons not living within the three counties could be admitted for £2 10s. weekly, provided there were vacant beds not required by residents of the three counties.

April 22nd.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Scottish Vital Statistics.

In the report of Dr. James Crauford Dunlop to the Registrar-General for Scotland, which is issued as a Parliamentary Blue-book, it is stated that the population of Scotland at the middle of the year 1906 is estimated to be 4,725,070, of whom 2,305,850 are males and 2,420,220 are females. This estimate is 49,467 more than the estimated population at the middle of the previous year. The total number of births registered in Scotland during 1906 was 131,920. The birth-rate for the year is 27·91 per 1000 and is the lowest rate recorded for Scotland. This is the first year in which the birth-rate has fallen below 28 per 1000. Previously to 1893 the birth-rate of Scotland was always over 30 per 1000. This fall of the national birth-rate, the report states, appears to be largely due to a fall in the birth-rate in the principal town districts, for in them the birth-rate of the year was 28·2, which is 0·7 lower than that of the previous year. Illegitimate births registered during the year numbered 8895 and amounted to 6·74 per cent. of the total births. The number of deaths registered in Scotland during the year 1906 was 75,535, a number which is 1059 more than in the previous year but 2031 fewer than the average number registered annually during the ten previous years. The death-rate for the year per 1000 of the estimated population is 15·99, which is, with the exception of the death-rate of 1905, the lowest recorded for Scotland. A section of the report deals with weather and its influence on mortality. It is stated that the only epidemic observed during the year which may be attributed to weather influences was in September, when diarrhoea was very prevalent, that epidemic being coincident with a spell of hot, dry weather.

The Dangers of Granting Lunacy Certificates.

A dastardly outrage was committed last week upon Mr. John Carswell in the streets of Glasgow. Mr. Carswell was standing on the pavement waiting for a car, when a man approached from behind and attacked him with a revolver. The attack was apparently the sequel to a medico-legal case

in November, 1905, in the Court of Session, which aroused widespread interest among the medical profession. The pursuer in the case, William Parves, had been detained in an asylum four months on certificates granted by Mr. Carswell and Dr. Marion Gilchrist. On being liberated he raised action for £10,000 in name of damages from each of the two medical practitioners for alleged unprofessional conduct in certifying him of unsound mind. The judge, Lord Pearson, after a long proof, had no hesitation in finding for the defenders, holding that the certificates were not granted by them wrongfully or without due inquiry, and that the pursuer at the time the certificates were granted was insane and suffering from an attack of subacute mania with homicidal tendency. The defendants, although they won their case, found at the end of the trial that in addition to the vexation and worry entailed they were each out of pocket £600 in the shape of expenses, part of which sum was afterwards refunded to them by the members of the profession in Glasgow and the West of Scotland who subscribed for the purpose. It was by this same man Parves that Mr. Carswell was attacked last week. The wounds inflicted were three in number, but fortunately did not affect a vital part, although an operation had subsequently to be done to remove the bullets. All the incidents of this case seem to emphasise very clearly the unfortunate position in which in the present state of the law a medical man may be placed in relation to the certifying of insane persons.

Cerebro-spinal Meningitis.

From the reports which come to hand it would appear that the epidemic of cerebro-spinal meningitis which has hitherto prevailed principally in some of the larger towns is tending to spread to the smaller burghs and country districts. Deaths from the disease are reported this week from Alloa, Kirkcaldy, and Forfar. I regret to learn that one of the assistant medical officers of health of the city of Glasgow has contracted the disease, but it is satisfactory to hear that he is progressing as favourably as can be expected.

April 23rd.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Typhus Fever in Oughterard.

THERE was a mild epidemic of typhus fever recently in the union of Oughterard which the rural district council stated to be due to famine. The Local Government Board reported that it was not due to insufficient food but to the insanitary state of the town. The medical officer has reported that there are now only six cases in the fever hospital, five of whom are about to be discharged. He says that he expects to have the hospital empty within a week and that the difference of opinion between the district council and the Local Government Board will probably end with the disappearance of the fever.

Adelaide Hospital, Dublin.

The annual meeting in connexion with the Adelaide Hospital took place on April 22nd, the Bishop of Ossory presiding. Captain R. Wade Thompson read the annual report of the managing committee, which showed that the entire debt of the hospital had now been paid off. Dr. Wallace Beatty read the medical report and Mr. Francis T. Heaston the surgical report. The chairman proposed the adoption of the reports, which motion was seconded by Dr. J. Little.

Cerebro-spinal Fever in Dublin.

The epidemic of cerebro-spinal fever, which was never severe or widely spread in Dublin, has now practically disappeared. At the last meeting of the managing committee of Cork-street Fever Hospital the medical superintendent reported that cerebro-spinal fever had ceased, only one patient, an infant now convalescent, being in the hospital. On April 19th three cases were reported at Portadown, one of which proved fatal, while another child was said to be in a state of collapse.

Cerebro-spinal Fever in Belfast.

At the weekly meeting of the Belfast public health committee held on April 18th it was reported that the large number of 30 cases of cerebro-spinal meningitis had been

reported during the previous week and during the week ended Saturday, April 13th, 20 deaths had been registered from the same cause. Altogether, since the commencement of the epidemic 313 cases of cerebro-spinal fever have been notified, with 200 deaths. Apart from "spotted fever" the number of cases of infectious diseases is less and the general death-rate for the week is 22.4, which is lower than during the previous week, when it was 25.0. Cerebro-spinal fever has broken out in Portadown.

Lurgan Workhouse.

Mr. Peddle, O.E., after examining and testing the drainage and sanitary arrangements of the Lurgan Fever Hospital, has reported to the guardians that he considers that the fever hospital in its present insanitary condition is unfit for habitation considering the purpose for which it was used. As a result of his examination and tests of the drainage and sanitary arrangements of the workhouse he condemns the whole establishment, and he reports his opinion that an urgent and radical change is absolutely necessary and essential to render the workhouse safe and sanitary. The matter—which is very urgent—is to be considered by a special committee of the whole board.

Holywood Water-supply.

Holywood, a small township on the east side of Belfast Lough, has a very unsatisfactory water-supply, for at a meeting of the urban council held on April 18th it was reported that the water was polluted owing to frogs and fish getting into the main from the clear-water basin.

Milk Control in Belfast.

The public health committee of Belfast has taken notice of the revelations that have been brought out at the Health Commission, for on April 22nd, for the first time in the annals of Belfast, two prosecutions took place for special offences in the milk trade. In one case a cowkeeper was prosecuted for milking a cow with a quantity of cow manure on his hands. He was fined 10s. and costs as it was a first offence, the magistrate saying that he should impress on his servants the importance of washing their hands when milking cows. In the second prosecution, a young man was found delivering milk from a cart in which there were two or three buckets of refuse (that is, stalks of vegetables, potato skins, old bones, &c., used for feeding pigs). It is a common practice in Belfast for this to occur, the prosecuting attorney stating that hundreds of milk-carts employed in the city carried refuse from the houses to which they supplied milk, and this is the very first attempt to correct a practice which the magistrate who heard the case said "must be stopped." The case was adjourned for four weeks to see if there was any repetition of the offence.

April 22nd.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

Lord Lister's Eightieth Birthday.

THE eightieth anniversary of Lord Lister's birthday was the occasion of many manifestations of esteem, not only from the German medical profession, but also from the general public. The leading daily newspapers published articles dealing with his life and work and describing him as one of the greatest benefactors of humanity. The medical journals, of course, made appropriate references to the event, but naturally did not enter into particulars regarding the transformation of surgery brought about by him, as this is known to every medical student. The *Münchener Medizinische Wochenschrift* provided a souvenir of the early days of antiseptic surgery by publishing a complete translation of Lord Lister's first article which appeared in THE LANCET of March 18th, 1867, with the heading, "On a New Method of Treating Compound Fracture, Abscess, &c., with Observations on the Conditions of Suppuration." Lord Lister is an honorary member of the German Surgical Association and the committee has sent him an artistically designed address which was previously read and approved at a meeting of the association held on April 4th. In this address it is said that to mark the progress which has been made in surgery since the time of Lord Lister's work it is customary to

speak of an ante-Listerian and a post-Listerian era and that the German surgeons are proud of the fact that they were among the first to recognise the importance of his great discovery.

The Russo-German Medical Society.

A Russo-German Medical Society has just been constituted in Berlin under the presidency of Professor von Leyden and Professor Hildebrandt of Berlin and Professor Bechterew of St. Petersburg. It is the aim of this new international medical society to promote cordial scientific and social relations between the Russian and German medical profession. Regular meetings at various places will be held, a library and a dispensary for indigent Russian patients will be established, and there is a prospect of a Russian hospital being founded in Berlin. It is said that some hundreds of the leading medical men of Germany and Russia have become members of the society.

The German Balneological Society.

The annual meeting of the German Balneological Society was held at Berlin from March 7th to 11th. Interesting addresses were read by Professor Hoffa on the modern treatment of diseases of the joints and by Professor Wassermann on the progress made in the diagnosis of infectious diseases. Dr. Determann of St. Blasien read a paper on the viscosity of the blood. He said that the viscosity was increased by the application of cold water, by sweating, and by passive congestion. A vegetarian diet and the application of hot water caused a decrease of the viscosity. The red corpuscles and the leucocytes were influenced in the same way as the viscosity. Dr. Baur of Naheim discussed the question whether a hypernormal blood pressure was a contra-indication against the application of carbonic acid baths. He said that in 75 per cent. of his patients the blood-pressure decreased by the Naheim treatment and that in the remaining cases which were complicated with Bright's disease he was convinced that an undesirable symptom developed. Dr. Grödel of Naheim said in the discussion that in these cases hip baths were preferable. Professor Strauss of Berlin spoke on the subject of pseudo-anæmia. He said that a paleness of the skin was often confounded with real anæmia and was therefore treated on erroneous principles. Pseudo-anæmia or ischæmia of the skin was a symptom of Bright's disease and of chronic lead poisoning and was a form of vascular spasm of nervous origin occurring in patients who suffered from diseases of the gastro-intestinal organs and especially from enteroptosis; sometimes it was a symptom of incipient tuberculosis. The proper treatment of pseudo-anæmia was a nourishing diet and hydrotherapy, avoiding the use of iron. Dr. Siebelt of Flinsberg spoke on the treatment of late symptoms of gonorrhoeal origin. Gonorrhoeal arthritis and neuritis were favourably influenced by mu baths; in cases of chronic gonorrhoeal disease of the female genital organs he had seen good results from the administration of pine-bark baths and prolonged irrigations with fluid in which the high amount of tannic acid and of resin was an efficient agent. Professor Kisch of Marlenbad read a paper on the constitutional form of lipomatosis. The condition was different from alimentary obesity and was as a rule, a symptom of pathological alteration of the blood. In treating it the usual reducing methods should therefore be avoided and improvement of the nutrition of the tissues should be aimed at. Dr. Selig of Franzensbad spoke on vibratory massage of the heart and stated that orthodiagraphy proved that a decrease of the dilated heart occurred under vibratory massage, while the healthy heart did not show any alteration. Cardiac asthma and cardiac failure were also favourably influenced. Dr. Löbel of Dornum spoke on the treatment of Bright's disease by mu baths. As these baths reduced the blood pressure and the polyuria, had a favourable influence on polyuria and the respiration they might be advantageously employed in Bright's disease. Dr. Steinsberg discussed the treatment of chlorosis by mu baths. Adopting the view that chlorosis was principally caused by an anomaly of the ovarian secretion he recommended hot mud baths because they acted especially on the ovaries and therefore not only relieved the symptoms but tended to correct the lesion on which the disease depended. Dr. Riedel of Berlin spoke on the physical treatment of headache. In hyperæmia of the brain and the meninges he recommended cold applications to the head and to the carotid arteries and Nügel's hand pressure. For headach

caused by anæmia, however, Nügeli's method failed. Massage was efficacious in the treatment of rheumatic and neurasthenic headache. Dr. Laqueur of Berlin spoke on the subject of radio-active baths. He had made experiments with baths, to which a radio-active salt called radiorial had been added. The emanation of radium had an obvious effect on the human organism as was shown by a reaction in arthritic joints and by the presence of radio-activity in the urine passed after the bath. In some cases of rheumatic and gouty arthritis an improvement was obtained. Dr. Immelmann of Berlin spoke on the treatment of chronic bronchitis and bronchial asthma by the x rays. He said that he had obtained favourable results in ten cases after a few administrations. Every administration in which the thorax had to be exposed from different sides ought to last about ten minutes; in cardiac asthma the method fails. Dr. Munter of Berlin read a paper on the physical treatment of certain complications of diabetes, with special reference to hydrotherapy, thermotherapy, mechanotherapy, and faradisation. He pointed out the indications for the use of these methods, but insisted on the necessity of employing them only as adjuncts to the dietetic treatment which was always the principal consideration in diabetes. Dr. Tobias of Berlin spoke on the physical treatment of nervous diarrhoea. In addition to an appropriate diet, hydrotherapy in the form of hip-baths, shower baths, and wet packing was recommendable, but local treatment should be avoided. Massage, gymnastics, and active sports were also contra-indicated. Among the other papers read before the congress mention may be made of those on the treatment of bronchial asthma by Dr. Goldschmidt of Reichenhall; on the refraction of the blood by Dr. Marcus of Fyrmont; and on the importance of splanchnicæ for the diagnosis of syphilis by Dr. Schuster of Aix-la-Chapelle.

April 22nd.

ITALY.

(FROM OUR OWN CORRESPONDENT.)

Italian Mineral Waters.

"A hydrological awakening" (*un risveglio idrologico*) is the appropriate description of Italy's practical recognition of her wonderfully rich but long neglected resources in mineral waters. I say "long neglected," because many of the resorts now in special favour were known to the ancient Romans and were even frequented in mediæval times, but within the last three centuries have seemed to share the general collapse that overtook well-nigh all things Italian till the national resurrection under the House of Savoy and its great Minister Cavour. Not a year passes without an addition to the rapidly multiplying list of "stazioni termali," involving not only the discovery of new mineral springs but the rehabilitation of old ones—their efficacy enhanced by all the modern appliances of scientific balneology and all the comforts of the up-to-date hotel. The British consultant, indeed the English-speaking practitioner all the world over, whose *clientèle* is recognised by economic Italy as one of her most desirable assets, is more and more likely to be asked by patients at the close of an Italian season to what thermal establishment they should resort to confirm or to supplement the "cure" they have been undergoing on the Neapolitan, Tuscan, or Ligurian Riviera or in this or that central winter city. To enable the said consultant or practitioner to answer that question promptly and effectively the Direzione Generale della Sanità has just issued a handsome volume on the "Acque Minerali d'Italia," containing full, correct, and succinctly detailed accounts of all the Italian balneary resorts now recognised by the profession. Well illustrated and rich in topographical indications the volume conveys the desired information in the Italian and French languages, and I have only to add that its editor is the veteran balneologist, Dr. Paolo Casciani, professor of medical hydrology in the Roman University, to convince the reader of its trustworthy and authoritative character. Italy has too long had the mortification of seeing the tide of invalid travel ebb away from her thermal establishments to transalpine rivals in no way superior while much more and artificially less interesting. Claims to the retention of that 11th Department puts forth the

volume above referred to—a volume, moreover, that would well pay reproduction in an English dress.

Homicide and the Abolition of Capital Punishment.

Every instance in which the British Home Office sees fit to commute the death penalty is hailed by the Italian press as an indication that the "Mother of Parliaments" from whom she has borrowed so much is in turn taking a leaf out of Italy's book and will ere long follow her example in abolishing capital punishments. Such being the case, it may be well to put in evidence the Italian record of homicides and from this to form a judgment how far she is warranted in the abolition of what other and less backward countries still find to be a deterrent to the would-be assassin. In the last statistical year there were in the Italian peninsula and islands 3108 murders and 93,368 *ferimenti* (woundings with intent)—that is, well-nigh 10 homicides per 100,000 of the inhabitants. In the year before the homicides were 3202 and the woundings with intent were 89,589, giving 1903 a precedence over 1902 of 3683 lethal crimes between homicides and woundings with intent. Germany's record in the matter of homicide is 1.88 per 100,000 of the population, England's 0.42, and Scotland's 0.37. Spain, which (according to Rossini) has the merit as regards Italy of saving the latter from the reproach of being last in the list of European civilisation, has 5.31 homicides per 100,000—about half Italy's percentage. THE LANCET has more than once gone into the etiology of Italy's "sinister priority" in *fatti di sangue* and recognised the force of her great criminal statistician, Baron Garofalo's contention that the main (not the sole) cause is the universal carrying of the knife. In fact 75 per cent. of lethal crimes are due to this weapon! Out of every 100 minors (between boyhood and adult age) charged with homicide, actual or attempted, 80 used the knife, which in all cases was, in size and form, of the kind "prohibited" by law. But, like many other things Italian, that law is "more honoured in the breach than in the observance," and in the southern provinces particularly man and boy "would sooner" (according to the Government organ the *Tribuna*) "go without bread than without the knife." Now and then the police make a raid on the public-houses and gambling haunts and impound some 40 or 50 knives as the result. But the culprits in whose possession they have been found and on whom a punishment little more than nominal (usually a fine) is inflicted contrive to replace the "prohibited" weapon next day with a view to operations offensive or defensive (generally the former). Flogging would be an effective means of suppressing the illegal carrying of the knife, but of all punishments that is the one to which Italian criminal reformers have the most rooted objection. And so, I fear, Italy will maintain her "sinister priority" in *fatti di sangue*, till education has done its humanising work—not a very promising outlook with "analfabetismo" (ignorance of the alphabet) one of the crying defects of the army and with 75 per cent. of the young married couples in Sicily and Calabria unable to sign the marriage lines!

Salt and Pellagra.

The *Rivista Pellagologica Italiana* has an important contribution from the pen of Dr. Camurri on the sparing use of salt in diet as a concurrent cause of the prevalence of pellagra in Italy. The alimentation of the peasantry is almost exclusively vegetarian (a fact that, *inter alia*, explains its low resisting power to such diseases as pneumonia), and after pointing out the rôle of chloride of sodium in digestion and assimilation and the prophylactic virtue it possesses in the system, particularly as against maladies originating in defective or perverted nutrition, he makes an appeal to the Government to remove the duty on salt and so to place an essential constituent of diet within the reach of the agrarian poor—the class most subject to pellagra.

April 20th.

THE PROTECTION OF CHILDREN.—We learn that the council of the National League for Physical Education and Improvement and the council of the National Health Society have jointly organised a meeting to be held on Thursday, May 2nd, at 5 p.m., at the Royal United Service Institution, Whitehall (by permission of the council), to advocate the protection of children by supporting the proposed legislation to keep children out of public-houses.

Obituary.

WILLIAM HENRY RANSOM, M.D., F.R.O.P. LOND., F.R.S.

Dr. William Henry Ransom, who for many years occupied a foremost position among the medical men of Nottingham, died on April 16th at his residence in Park Valley in that city. Considering his great age and the fact that he was more or less of an invalid for the last three years the sad event was not altogether unexpected.

Dr. Ransom was born in 1823 at Oromer, in Norfolk, where his father was a shipowner and had also been at sea as a captain. He received his school education at Norwich and when 16 years of age he was apprenticed for four years to a medical man practising in King's Lynn, after which he entered as a student at University College, London. Here he was very successful in his class work, gaining several gold medals both at University College and in the University of London; it is also on record that in 1845 he came out first at a competitive examination in which the late Professor Huxley was his principal opponent. He held the usual residential posts at University College Hospital and afterwards spent a year or two abroad, studying in Germany and Paris. In 1850 he graduated as M.D. in the University of London and settled in Nottingham in the same year. About this time he was busily engaged in investigating the embryology of fish and some points in vegetable pathology, especially the development of galls and tumours in plants and trees. The results of his work on embryology appeared in the publications of the Royal Society in 1854 and 1867, and he was admitted F.R.S. in 1870. In 1869 he was elected F.R.O.P. Lond. In 1854 he received the appointment of physician to the Nottingham General Hospital, a position which he retained for 36 years, only resigning in 1890, and being then elected consulting physician. He still continued to see patients, however, and did not retire from active professional work till about eight or ten years ago. In 1892 the annual meeting of the British Medical Association was held at Nottingham and Dr. Ransom, as president of the section of medicine, delivered an address which was for the most part devoted to questions of vegetable pathology—namely, to plant diseases which, in his opinion, corresponded with inflammatory processes in animal tissues. All such reactions in plants formed galls or witch-knots. The irritants might be of various kinds but those which he chiefly described were of insect origin, the common oak apple and the common nut gall being familiar examples. As late as last year he published a summary of his views in the form of a treatise entitled "The Inflammation Idea in General Pathology."

Dr. Ransom entered heartily into the volunteer movement which commenced about 1859 and served as a private in the 1st Notts Volunteer Rifle Corps (Robin Hoods) soon after its foundation. He took an active part in local politics as a strenuous worker for the Liberal party and in particular was deeply interested in all educational questions. He was an enthusiastic supporter of the Nottingham University College and for a long time was a member of the governing body. He was also a governor of Nottingham High School as a representative of the University of London. About 1870 he designed a form of gas-heated stove for the disinfection of clothing, bedding, and other articles used by patients suffering from infectious diseases. The principle was a good one and the stoves were much used for many years. In 1860 he married Miss Elizabeth Bramwell who died some years ago. They had three sons, one of whom (Dr. William Bramwell Ransom) succeeded his father as physician to the hospital in 1890.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced: Dr. Sukhchinski, formerly professor of pharmacology in the Military Medical Academy, St. Petersburg.—Dr. Ottomar Domrich, body physician to the Duke of Saxe Meiningen and formerly honorary professor of physiology in the University of Jena.—Dr. Moritz Hutzler of the Gisela Children's Hospital, Munich.—Dr. Hermann von Burckhardt, one of the most eminent surgeons in Würtemberg, in his sixtieth year, from carcinoma of the stomach. He was formerly assistant to Professor Thiersch of Leipzig, but had

been in charge of the surgical department of the Katherine Hospital in Stuttgart for more than 20 years. His contributions to medical literature on surgical topics were numerous.—Dr. Andrew Willard, formerly professor of hygiene in the University of Vermont.—Dr. Micé, formerly professor of chemistry in the Medical Faculty of the University of Bordeaux.—Dr. John H. Brinton, formerly professor of surgery in Jefferson Medical College, Philadelphia.

Medical News.

SOCIETY OF APOTHECARIES OF LONDON.—At examinations held in April the following candidates passed in the subjects indicated:—

Surgery—H. S. Burnell-Jones (Section I.), Cardiff, Leeds, and London Hospital; M. P. Emrys Jones (Sections I and II.), Cambridge and Manchester; C. S. Spencer (Sections I and II.), Manchester; F. A. K. Stuart (Sections I. and II.), St. Mary's Hospital; and E. B. C. Vollet (Sections I. and II.), Paris.
Medicine—H. J. W. Barlow, Middlesex Hospital and Lyons; R. J. Crew (Section I.), Guy's Hospital; G. B. Mc-sanger (Section II.), Westminster Hospital; R. J. W. McKane (Sections I. and II.), Leeds; J. P. McQueen (Section I.), King's College Hospital; S. K. Poole (Section I.), Guy's Hospital; H. Sutcliffe (Sections I. and II.), Leeds; and W. V. P. Teague, London Hospital.
Forensic Medicine—H. J. W. Barlow, Middlesex Hospital and Lyons; J. F. McQueen, King's College Hospital; E. Sutcliffe, Leeds; and J. S. Ward, Sheffield.
Midwifery—E. M. Adam, Charing Cross Hospital; H. E. Battle, Leeds; J. Cree, Belfast; M. P. Emrys-Jones Cambridge and Manchester; H. A. Fenton, St. Mary's Hospital; H. E. Middlebrooke, London Hospital; R. J. W. McKane, Leeds; B. Robertshaw, Manchester; R. Rowlands, Glasgow; and H. Stanger, Leeds.
 The diploma of the Society was granted to the following candidates, entitling them to practise medicine, surgery, and midwifery: H. A. Fenton, C. S. Spencer, F. A. K. Stuart, and W. V. P. Teague.

UNIVERSITY OF DURHAM.—At examinations for the degree of Bachelor of Medicine held in April the following candidates satisfied the examiners:—

FIRST EXAMINATION.

Elementary Anatomy and Biology, Chemistry and Physics.—*Second-class Honours:* William George Bendle, College of Medicine, Newcastle-upon-Tyne. *Pass List:* Francis Percy Evers and William Joseph Hickey, College of Medicine, Newcastle-upon-Tyne; Carl Johan Valfrid Swahnberg, Charing Cross Hospital; Harold Price Stephens, Madras Medical College; and Robert Wilkie Smith, Alfred Tulloch Thompson, and Thomas Ruddock West, College of Medicine, Newcastle-upon-Tyne.
Elementary Anatomy and Biology.—John Bain Alderson, Richard Murray Barrow, Roger Errington, David Farquharson, Sarah Louisa Green, Thomas Albert Hindmarsh, Arthur Sydney Hopgood, Tom Merchant Hopgood, Frank Hutchinson Kennedy, Richard Bridge Lilly, John Lumb, and Benjamin Bell Noble, College of Medicine, Newcastle-upon-Tyne; Thomas Alfred Peel, Royal College of Surgeons, Ireland; and Arthur Hyde Wear, College of Medicine, Newcastle-upon-Tyne.
Chemistry and Physics.—Everard Cecil Abraham, College of Medicine, Newcastle-upon-Tyne; Louis Ernest Seide Gellie, Edinburgh Medical School; Harold Llewellyn James, Guy's Hospital; Hubert Vere Leigh, University College, Cardiff; George Outburt Mura McConigle, College of Medicine, Newcastle-upon-Tyne; Oswald Sinclair Norton, Guy's Hospital; and Henri René Guillaume Vander Beken, London Hospital and College of Medicine, Newcastle-upon-Tyne.
Elementary Anatomy.—William Smith, B.Sc., College of Medicine, Newcastle-upon-Tyne.

SECOND EXAMINATION.

Anatomy, Physiology, and Materia Medica.—*First class honours:* Jabez Ethelbert Dainty, College of Medicine, Newcastle-upon-Tyne. *Second-class honours:* Charles Marks, College of Medicine, Newcastle-upon-Tyne. *Pass List:* Hubert Cyril Willoughby Allott, Wilfred Barker, and John Aklinda Caulerick, College of Medicine, Newcastle-upon-Tyne; Francis Hamley Fawkes, St. Mary's Hospital; Herbert Edward Fullerton, Cyril John Henderson, and Francis Frederick Trevor Hare, College of Medicine, Newcastle-upon-Tyne; Satyen Mozumdar, St. Bartholomew's Hospital; William Reynolds, Guy's Hospital; William Sacco, College of Medicine, Newcastle-upon-Tyne; Dorothen Mary Tudor, London School of Medicine for Women; and William Robert Eistob Unthank and Charles Leslie Wigan, College of Medicine, Newcastle-upon-Tyne.

FOREIGN UNIVERSITY INTELLIGENCE.—*Berlin:* Dr. Wilhelm Dieck and Dr. Fritz Williger have been appointed Extraordinary Professors of Odontology.—*Bonn:* Dr. Nussbaum, Extraordinary Professor of Anatomy and Custos of the Anatomical Institute, has been appointed Ordinary Professor and Director of the Institute, in succession to Dr. v. Lavalette St. George, who retires.—*Chicago (North-Western Medical School):* Dr. A. E. Halstead has been appointed Professor of Surgery.—*Erlangen:* Dr. Oskar de la Camp of Marburg has been appointed Professor of

Sanitary order issued by the Local Government Board in 1900 contemplates that young children in a workhouse shall be dieted in accordance with the directions of the medical officer and with careful regard to the requirements of each individual child. In many Poor-law establishments the milk is treated in the manner suggested by the honourable Member, but looking to the circumstances I have mentioned, and also to the division of medical opinion on the question of the best way of dealing with milk for children, I doubt the expediency of issuing a general order on the subject at the present time.

The Consumption of Tuberculous Milk.

Mr. MARKS asked the honourable Member for South Somerset, representing the President of the Board of Agriculture, whether in view of the opinions as to the danger to human life from the consumption of tuberculous milk expressed in the interim report of the Royal Commission appointed to inquire into the relations of human and animal tuberculosis, he would now reconsider the advisability of issuing a general order to compel the notification of cases of disease of the udder in cows which are kept for the purpose of selling their milk. Sir EDWARD STRACHEY furnished the following written answer: The report of the Commission is receiving our careful consideration. The matter is, however, one primarily affecting the public health, for which my right honourable friend, the President of the Local Government Board, is responsible, and with whom my noble friend proposes to confer on the subject. We quite recognise its importance.

The Patents and Designs Bill.

The Patents and Designs Bill, which is under the charge of Mr. LORD GEORGE, the President of the Board of Trade, was read a second time after a debate lasting several hours.

The Butter and Margarine Bill.

Sir EDWARD STRACHEY, in moving the second reading of the Butter and Margarine Bill, said that it was founded on the recommendations of the Select Committee which sat last year. Some of the evidence given before that committee showed that there had been a great deal of adulteration and "faking" of butter. In a case taken recently against a creamery company it was stated that the profits made by adding lardine to butter were £5650 in 15 months. Accordingly there was a real need for a Bill which stopped the adulteration of butter at its source. By the provisions of the Bill the existing law with regard to registration of manufacturers of margarine was extended to butter factories and to premises where butter substitutes were made. Powers of inspection were provided in order to prevent fraudulent trade. It was also laid down that no butter for consignment containing more than 16 per cent. of moisture should be sent out of a butter factory. There were also regulations for the sale of butter mixture and imitation butter, the description and name of which would have to be approved by the Board of Agriculture. No description or name which would lead the public to believe that the imitation was genuine butter would be sanctioned. The debate on the Bill was adjourned.

THURSDAY, APRIL 18TH.

Unvaccinated Children in Derby.

Mr. BELL asked the President of the Local Government Board whether he was aware that Dr. R. W. Johnstone, one of the Local Government Board inspectors, had instructed the vaccination officer of the Derby union to re-commence prosecutions under the Vaccination Acts; whether he was aware that there were between 25,000 and 30,000 children unvaccinated in Derby; and whether the parents of all those would also be prosecuted; and, if so, would those of the longest standing be proceeded against first and continued on in that order; and whether Dr. Johnstone's action had the sanction of the Local Government Board.—Mr. BAKER replied: A new vaccination officer has recently been appointed at Derby and Dr. Johnstone acted properly in advising him as to his duties, one of which is to take all reasonable steps to put the Vaccination Acts in force. I am aware that there are in Derby a large number of unvaccinated children. It is not contemplated that proceedings will have to be taken in all these cases. I understand that Dr. Johnstone told the vaccination officer that he should use all possible means of persuasion to induce parents to comply with the law, and if this failed he should institute proceedings in a limited number of cases with a view to securing its observance. The selection of the cases would rest with the vaccination officer.

Small-pox Epidemic at Metz.

Mr. LEITCH asked the Secretary of State for Foreign Affairs whether he could give any information about an alleged epidemic of small-pox at Metz which began last July, had assumed alarming proportions, had seriously affected trade and industry, and had caused the usual festive festivities to be abandoned; could he say if the population of Metz was protected by vaccination and revaccination with the same thoroughness as the rest of the German Empire; and if he had not this information, would he send a Special Commission to inquire and report.—Sir EDWARD GREY answered: I have no information other than that supplied to me by the honourable Member. His Majesty's Ambassador at Berlin would no doubt ask the German authorities to facilitate any inquiry which competent British authorities may desire to make independently in the interests of medical science, but I have not been advised that the occasion is one which requires the appointment of a Special Commission by His Majesty's Government.

The Conscientious Objector.

Dr. BURNHARDT asked the Secretary of State for the Home Department whether his attention had been called to the fact that a Glasgow applicant applied twice to the magistrates at the Brentford Magistrates' Court, on March 2nd and 15th, for an exemption under the Conscientious Objectors Act, 1895, and was refused; and what steps he proposed taking to give the conscientious objector a fair hearing.—Mr. GLADSTONE replied: I have received two letters calling my attention to the case. The amendment of the law is under consideration by my right honourable friend the President of the Local Government Board.

Care of Midwives.

Mr. PARKER, on behalf of Mr. JOWETT, asked the Secretary of State

for the Home Department whether, in view of the fact that during the six months ending March 20th last there were 54 cases of anthrax reported to his office, 14 of which were fatal, and that in eight of the 54 cases his officers had failed to ascertain the kind of material upon which the person attacked had been engaged, he could see his way to make such arrangements as would in future enable him to inform himself as to the materials which had carried the infection.—Mr. GLADSTONE answered: I understand that the honourable Member refers to some statistics of anthrax with which I recently furnished him. In the eight cases in which a return was made of "material not ascertained," the reference intended was to the material by which the infection was actually conveyed and not to the material on which the worker was engaged. It is sometimes impossible—especially in the case of miscellaneous occupations such as that of dock labourer, carter, or the like, in which six out of the eight cases occurred—to trace the source of the infection. A mere entry of the material on which the worker had been engaged would not serve any useful purpose and might be actually misleading. Every effort, of course, is made by the medical inspector of factories to trace the source of infection in each case, but it is difficult to see what further arrangements, especially in the case of miscellaneous employments such as those mentioned, can be made to insure a knowledge of the particular material which has carried the infection. I should add that the figures quoted by the honourable Member refer to a period of nearly nine months and not six, as stated in the question.

Mr. PARKER, on behalf of Mr. JOWETT, further asked the Home Secretary whether, in regard to all future cases of anthrax which occurred at seed-crushing, oil-extracting, and bag-making works, he would endeavour to ascertain the kind of material from which the bags used in seed-crushing and oil-extraction operations had been made and, in the case of bag-making works, what materials were being used.—Mr. GLADSTONE said in reply: Yes, Sir, this will be done.

The New Hospital at Tidworth Barracks.

Answering Captain FABER, Mr. HADDAN stated that it was not possible to give a definite date at which the building of the new hospital at Tidworth barracks would commence, but the work in preparation for the new hospital was so far advanced as to render it possible in a short period to arrange a contract.

The Sanitation of Dumbarton.

Mr. ROBERT DUNCAN asked the Secretary for Scotland whether the Local Government Board in effect ordered the conversion of the domestic sanitary system of the burgh of Dumbarton, as stated by the Provost before a Parliamentary Committee on May 8th, 1906; whether he was aware that the conversion referred to had resulted in the domestic sewage of over 20,000 inhabitants being discharged into the tidal pools of the River Leven without purification of any kind; and whether, in view of the condition of the river, he would insist upon such proceedings being taken as would render the conversion of the sewage system harmless to the natural purity of the river.—Mr. SIMONDS stated, in reply: In 1903 the Local Government Board pressed the local authority to take steps to remove certain nuisances. I understand that the local authority has also in hand the extension of all outlets into the river so as to prevent the deposit of sewage on the shores above low-water mark. When these have been completed it is believed that a great improvement will be effected in the condition of the river bed.

Sanitary Accommodation for the Royal Irish Constabulary.

Mr. SLOAN asked the Chief Secretary to the Lord Lieutenant of Ireland to what extent separate sanitary accommodation was provided for the wives and children of members of the Royal Irish Constabulary living in barracks; whether there was any exception to the rule that one convenience only was provided for men, women, and children, as well as prisoners of both sexes; what means had the constabulary authorities of ascertaining that the sanitary accommodation of Royal Irish Constabulary barracks was wholesome; and whether the surgeon to the force exercised any supervision in this respect.—Mr. BIRRELL replied (in a written answer): Separate sanitary accommodation for women and children is almost invariably provided at the larger stations, but it is not possible to provide such accommodation at many of the small rural stations where the premises are small. The latter stations are usually occupied by one married constable only and in such cases the necessity for separate sanitary accommodation is not so marked. Constabulary stations are periodically inspected by county and district inspectors, as well as by officers from headquarters, so that ample opportunity is afforded for bringing to notice any defects in the sanitary arrangements. The local medical attendants advise on all matters affecting the health of the men and their families and the sanitary condition of the barracks. The surgeon of the force, who is attached to the depot, exercises no supervision in this respect.

The Training of Midwives.

Mr. ASHTON asked the President of the Local Government Board whether he was aware that there were only 19 counties in England and Wales in which there were institutions approved by the Central Midwives Board for the training of midwives; and that there were only 52 approved institutions in England and Wales, of which 35 were voluntary and only 17 poor-law institutions, of which again six were in London and only 11 in the rest of the country; whether he would say whether in the voluntary institutions the probationers had to pay fees; and whether in the poor-law institutions they paid none; and if he could state in what way the fees payable in the voluntary institutions were generally disposed of.—Mr. BURNHARDT gave the following written answer: I understand that the figures in the question are substantially correct, the precise figures being as follows:—Counties in England and Wales in which there are institutions approved by the Central Midwives Board for the training of midwives, 19; approved institutions in England and Wales (of which there are 35 voluntary, i.e., non-Poor-law provisions), 51. The Paddington, Farnham, and Epsom infirmaries have not been approved. I have no information as to the payment and application of fees in voluntary institutions. In Poor-law institutions there are usually no fees.

FRIDAY, APRIL 19TH.

An Outbreak of Typhus Fever in Ireland.

Mr. O'MALLEY asked the Chief Secretary to the Lord Lieutenant of Ireland whether his attention had been called to the resolution of the Oughterard rural district council, passed on April 11th, in which it was stated that the outbreak of typhus fever in the district was due to famine conditions rather than to the insanitary condition of the houses where the outbreak originated, as reported by the Local Government Board medical inspector; and whether he would institute adequate relief works to cope with the distress that prevailed in the Oughterard union.—Mr. BIRRELL replied (by written answer): According to the resolution referred to the district council appears to consider that the fever is not due to the insanitary conditions described by the Local Government Board's inspector, inasmuch as the same conditions have always prevailed at Oughterard. The Board, however, is satisfied that the contention of the council has no support. The state of things found by the inspector constitutes a perpetual menace to public health and if district councils were to be absolved from all responsibility in cases in which insanitary conditions have existed for a long time there would be an end of sanitary reform in Ireland. The Local Government Board is entirely satisfied that there is no foundation for the suggestion that famine prevails in this union and has caused the outbreak of fever. The guardians are bound by law to keep their relieving officers in funds for the relief of all urgent cases. They are well aware of their statutory obligations and powers and the Board cannot consider that they would be so oblivious of their duty to the destitute poor as to allow them to suffer from want of food to an extent which would cause famine fever. The Local Government Board has afforded through the spring months, and is still affording, employment to many hundreds of families in the poorest parts of this union where distress was apprehended and the rates have thereby been relieved of a considerable burden. The Board is satisfied that the resources of the union will be ample to enable the guardians to provide any further relief that may be necessary.

MONDAY, APRIL 22ND.

Dangerous Lunatics in Scotland.

Major ANSTRUTHER-GRAY asked the Lord Advocate whether a dangerous patient in a district asylum might be discharged and handed over to relatives relieved, but not cured; and, in that case, whether the lunacy authorities had no further charge or responsibility.—Mr. SHAW replied: A patient who, when admitted, was dangerous may, on the sheriff being satisfied and on medical certificates, be discharged when this can be done without risk or injury to the public or the patient. As to the latter part of the question, it does not appear to me that there is any such charge or responsibility if the procedure is correctly followed.

Criminal Lunatics in Scotland.

Major ANSTRUTHER-GRAY asked the Lord Advocate whether he would consider the advisability of taking the necessary steps to insure that all cases of dangerous lunatics who had committed assault resulting in loss of life should be dealt with in a criminal lunatic asylum instead of relegating them to a district asylum. The honourable and gallant Member further asked the Lord Advocate whether, seeing that the presence of criminal lunatics who had committed murder was detrimental to the general freedom from severe discipline in district asylums, the beneficial effect of what was termed the open-door system being acknowledged, he would take the necessary steps to keep the district asylums free from criminal lunatics who had committed murder or attempted murder as far as possible.—Mr. SHAW answered: The sending of these cases to a district asylum is no doubt warranted if the procedure under the 15th Section of the Lunacy Act of 1857 is adopted. I may say, however, that the other course, which is also correct in law, appears to me to be more advisable in practice—viz., that when crime has been committed by a lunatic the criminal authorities should deal with it in accordance with their regular powers under Sections 87 and 88 of the Lunacy (Scotland) Act, 1857. There may, no doubt, be exceptional cases, but my desire is that the practice which I think to be preferable should be adopted.

Plague in India.

In answer to Dr. RUTHERFORD, Mr. MORLEY stated (in a written answer) that the recorded deaths from plague in India, including native states, from September, 1896, to end of March, 1907, were approximately 5,012,000. The monthly returns which he received from India showed 58,438 deaths in January, 93,397 deaths in February, and 171,522 deaths in March of the present year. The provinces most affected were the United Provinces, the Punjab, Bengal, and Bombay. He promised to ask the Government of India for a return bearing upon the number of medical men on special plague duty in that country.

The Sanitary Service in India.

Dr. RUTHERFORD asked the Secretary of State for India whether the recommendations to the Indian Government by Professor Simpson, late medical officer of health of Calcutta, to introduce a special sanitary service composed of Indian medical men and women supervised by European experts, and repeated in his work on plague, had been carried out to stay and prevent the ravages of plague.—Mr. MORLEY replied (in a written answer): I would refer my honourable friend to the published resolution of the Government of India, dated Sept. 8th, 1904, creating the office of sanitary commissioner, in which is described the action taken by them on various schemes for the constitution of a separate sanitary service and the difficulties, financial and administrative, in the way of an effective and speedy reorganisation. Much has been done to strengthen and improve the existing sanitary agency at the disposal of local governments, especially in districts where plague is liable to occur. The subject is still engaging the anxious consideration of the Government.

TUESDAY, APRIL 23RD.

Medical Examinations for Lead Poisoning.

Mr. WINGWOOD asked the Secretary of State for the Home Department whether his attention had been called to a paper read before the English Ceramic Society by Dr. Shuttlebotham, an acknowledged

authority in lead poisoning, in which he urged that certifying surgeons should be provided with a private room in each factory for the periodical examination of work-people, to avoid the present superficial examination in semi-public offices, and whether the Home Office would inquire into the conditions under which these examinations were carried on with a view to possible improvements.—Mr. GLADSTONE replied: I have not myself seen the paper referred to, but in the covering letter issued with the earthenware special rules of 1901 manufacturers were informed that arrangements should be made to allow due privacy for the medical examination required under the rule.

Notification of Births.

Lord ROBERT GEOL, under the ten-minutes rule, asked leave to introduce a Bill to provide for the early notification of births. He said that infantile mortality existed to a great extent in this country, and every year there occurred 120,000 deaths of infants under the age of one year, and of these probably it was not extravagant to say that 60,000 might be saved if proper precautions were taken. This state of affairs entitled the Bill to the earnest consideration of the House. It meant that out of every 1000 children born, 145 died before they reached the age of one year. The number of deaths in particular localities went as high as 250 or 300 or even 400 out of every 1000. He had said that half of these might be saved. That was not a matter of speculation because in some colonies the death-rate was not higher than 70, and even in some of our own counties it was not higher than 84. The seriousness of this state of things was not lessened by the fact that, although the death-rate in other cases had been diminished by the sanitary measures taken in this country, the infant death-rate had not declined to any extent. It remained practically stationary. The main cause of this state of affairs might be summed up in two sentences. It was due mainly (1) to the neglect of the mother of her own health before the birth of the child, and (2) to the neglect of the health of the child immediately after it was born. More than any one cause ignorance was at the bottom of the deaths of these unhappy children. Something might eventually be done by the improvement of elementary education, but he did not think it was necessary to wait for such a process. He thought something might be done by skilled advice, skilled assistance given to the mother during her early days of motherhood. He was glad to know that there existed a number of societies which have charged themselves with the duty of giving this advice and assistance. In Huddersfield some very remarkable results were obtained through the great influence of Alderman Broadbent. One difficulty was often met by those who were working in this field. It was too often the case that no notification of the existence of a child was given before it was dead. Under the present registration law six weeks were allowed for registration to take place. One-third of the children who died in the first year died within six weeks of their birth. It was therefore quite futile to have a system of registration which did not come into operation until six weeks had elapsed. It was solely with the object of remedying that defect that he had been asked to introduce the present Bill. It was modelled upon the provision which already existed at Huddersfield. It provided that there should be within 48 hours of the birth of every child a notification of its birth sent to the medical officer of health. That notification could be given in the simplest way without any formalities. It might be given by a post-card. The duty was thrown upon him, upon anyone who has been on attendance on the mother. Another provision provided that notification should be made in the cases of stillborn children. He would not trouble the House with reasons for that at the present time. It was a matter of very great importance. That was the whole Bill and he asked the House to consider very carefully the seriousness of the evil. He knew that there were some cheerful optimists who flattered themselves that a check on population was not an undesirable thing. He was utterly unable to agree with that view. Apart from what seemed to him its essential brutality it was now agreed to be utterly unsound in political economy. There were others who thought that this loss of infant life operated as a store, who thought that this loss of infant life survived. He believed by means of which only the fittest survived. He believed that to be equally untrue. Not only was it untrue but it was emphatically true that many of those who survived this ordeal went into life maimed and weakened and unfit to bear its struggles. This was absolutely a non-party matter. He ventured to hope that it would also be a non-contentious measure. This proposal of his had received very general support, not only from experts in sanitary matters, but also from the Association of Municipal Corporations. It came to the House with a great body of authority behind it, it was supported by Members in all parts of the House, and he hoped they should have the sympathetic support of the Government, and that the measure might be passed into law before the close of the present Session.

Sir HENRY CAMPBELL-BANNERMAN—Hear, hear.
Leave having been given the Bill was introduced and read a first time.

WEDNESDAY, APRIL 24TH.

Street Accidents in London.

Mr. COOPER asked the Secretary of State for the Home Department whether the Departmental Committee appointed last year to consider and report upon the question of the provision of ambulances for street accidents in London had finished its inquiry; and when its report would be published.—Mr. GLADSTONE answered: I am not in a position at present to say when the inquiry will be completed and the report issued.

ANDERSON.—On April 18th, at Sanfield, Braintree, North Devon, wife of Frederick T. Anderson, M.D., of a son.

BROWN.—On April 15th, at Park-road, West Kirby, Cheshire, the wife of W. McIntyre Brown, M.B., Ch.B., of a daughter.

JEFFREY.—On April 20th, at Clapton-square, N.E., the wife of Fr Jeffrey, M.D., of a daughter.

MARRIAGES.

REYNOLDS-BLACKWELL.—On April 24th, at Arlington, Chesham, Berkshire, by the Rev. W. H. Blackwell, father of the bride, and the Rev. F. S. Slater of Newick Park, Surrey, the late Edward Reynolds, M.R.C.S. Eng., L.R.C.P. Lond., youngest son of the late Edward Reynolds of Paxton Hall, St. Neots, Huntingdonshire, Esquire, J.P., to Geraldine Maud, youngest daughter of Rev. W. H. Blackwell, Rector of Arlington.

STRATFORD-GOULD.—On April 17th, at St. Peter's Church, 7 A Park, Howard M. B. Stratford, M.R.O.S., L.R.C.P. Lond., to Katherine Lucy, elder daughter of Mr. and Mrs. Gould, of Bel Park-gardens, N.W.

DEATH.

LOWRY.—On April 18th, at Pakhol, China, in his 52th year, John H Lowry, M.B., Imperial Maritime Customs.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

A PATIENT'S RASH DECISION.

OUR CORRESPONDENT has drawn our attention to a paragraph in the *Sportsman* of April 19th alluding to the condition of the jockey Birch, who fractured his spine whilst riding last year at Ascot. It appears that the unfortunate jockey, who was having a long surgical advice, decided to put himself under an unqualified person for treatment, with the natural result that his attendants withdrew from the case. Whether *post hoc* or *propter hoc* we know not, but according to the *Sportsman*, the paragraph is not only as bad as ever but is complicated by the presence of a double bed-sore; we further learn that Birch "thinks he has been rash in the decision he took and were he to come again he might act otherwise than he did." This is very probable. Our chief object in calling attention to the case is to applaud this very proper comment with which the *Sportsman* concludes its paragraph: "The medical profession, of course, as such, is much too high-minded to harbour spite or even measure. Its business is to cure where and when it can, without respect of persons. Should Birch ask anew for the profession's help would certainly, we take it, be given him when he had complied with the unalterable and, indeed, not unreasonable, requirements of clinical etiquette." If non-medical journals more frequently supplied so right-minded a view of professional principles the public might soon become educated to a truer understanding of them.

FEMALE PILLS.

To the Editors of THE LANCET.

Enclosed a sheet of lavatory paper from the ladies' lavatory at Harbour Station, South-Eastern and Chatham Railway. It is interesting to know who is responsible for its selection and if they receive for doing so. I am, Sirs, yours faithfully,
M.D.

The paper enclosed bears the following inscription:—

LADIES.

TIME TAKES ALL THINGS BUT DR. JOHN HOOPER'S

FEMALE PILLS,

which were universally known in 1743 and still stands the Premier Remedy for all Female Complaints. A Coupon is placed round each box of the genuine Dr. John Hooper's Female Pills, and Bonuses will be given to the persons sending in the greatest number of these Coupons to Messrs. May, Roberts, and Co., 9, Clerkenwell-road, London, E.C., by the 30th June, as follows, viz.:—

£5 5s. for the person sending in the largest number.

£3 3s. for the person sending in the second largest number.

£2 2s. for the person sending in the third largest number.

I do not endorse the suggestion of our correspondent that anyone has been bribed to assist in the dissemination of quack circulars, but I think that the South-Eastern and Chatham Railway might supply passengers carrying papers free from nasty advertisements.—Ed. L.

"CHRISTIAN SCIENCE" AND MEDICINE.

The issue of the *Glasgow Herald* of April 19th appears a report of a lecture on "Christian Science" at which it is reported that "Dr. F. F. Wilding, Manchester," presided. Dr. Wilding is reported to have said "that 19 years of his life had been spent in the study of medicine." His daughter who had suffered from tubercular disease and who was regarded as incurable was healed when "Christian Science" was resorted to. Dr. Wilding's name does not appear in the current Medical Register. In THE LANCET of April 21st, 1904, page 1225, we mentioned that we had received a copy of the *Christian Science Journal* which contained an experience "of one who practised medicine for 12 years and then came to Christian Science." This gentleman was named Mr. W. F. Wilding, who then signed himself M.R.C.S., L.R.C.P. On referring to an old number of the Medical Directory we see that Mr. Wilding qualified in 1830. If this be so he either took an unconscionable time to get qualified or he has been studying medicine ever since he came to "Christian Science," or else how does he make up 19 years? It would be interesting to know whence Mr. Wilding derives his title of "Doctor."

BLACKFELLOW DOCTORS.

Dr. A. W. Howitt's "Native Tribes of South-East Australia," published in 1904, a most interesting account is given of the "medicine-men" or "blackfellow doctors" of Australian tribes, now fast becoming extinct. The medicine-men would seem to be the ancestor of the prototype rather of the medical scrooge than of the scientific medical man of post-Renaissance times. His powers are chiefly of the supernatural order. "He is every where believed to have received

his dreaded power from some supernatural source, or being" or from the spirits of ancestors. This power enables him to inject diseases, as it were, into people at a distance, as well as to cure disease by striking at its secret originator, who is usually a rival medicine-man in a neighbouring tribe. He can also preserve people from disease. He works with charms, and individual medicine-men, or each group of them, possess charms peculiar to themselves. In all cases the "blackfellow doctor" "is credited with being able to see men in their incorporeal state, either temporarily as a wraith, or permanently separated from their body as a ghost, which is invisible to other eyes. He can ascend to ghost-land beyond the sky, or can transport himself, or be transported by the ghosts, from one spot of earth to another at will, much after the manner of the Buddhist Arhat. He can, it is also thought, assume animal forms or control the elements." Savages all the world over, as Dr. Howitt further points out, have similar beliefs, which linger here and there, even among the most civilised peoples. Besides being magicians, medicine-men are often headmen of tribes, councillors, rain-makers, orators, or song-makers. Dr. Howitt does not believe them to be conscious quacks. Such imposture as they practise is usually the outcome of a desire to bolster up supernatural powers in which they believe. In this they resemble "Mr. Sludge" the medium, whose swindling was a form of *esprit de corps*. Whatever they may be, medicine-men undoubtedly are the clever people, the "intellectuals" of savage society, and as such they command sympathy and respect among their fellows.

THE MARINE BIOLOGICAL ASSOCIATION OF THE WEST OF SCOTLAND.

FOR some time past there has been a good deal of difference of opinion among those who take an interest in this association as regards the policy and objects of the association, and within the last few weeks a crisis has been reached in its affairs. The main objects of the association as carried out at the marine station at Millport are understood to be threefold—viz.: (a) the investigation of the marine fauna and flora of the Clyde sea area, which implies a systematic biological survey of the area involved; (b) educational work, in the way of encouraging the visits of scientific societies, holding classes at suitable times for teachers and others, and in every possible way encouraging and assisting amateur marine biologists; and (c) the maintenance of such features as may attract the general public, and these are represented at Millport by the Robertson Museum and the aquarium. At the annual general meeting of the association the committee of management was severely criticised on the ground that it was laying too much stress on the first part of the association's work and allowing the more popular sides to fall into abeyance to such an extent that the station would gradually tend to become more and more of interest to the expert and special worker in biology, while it would inevitably become of less help to the amateur marine biologist and of little interest to the general public. As an amendment to the report of the committee on the work of the association was carried by a small majority, the committee resigned and the meeting proceeded to elect a new committee. Some time must elapse before it can be seen on what lines the new committee intends to proceed, but it is to be hoped that it will be realised by those who have control of the association that to carry on successfully the Millport Marine Station and to conserve the interests of all subscribers the research, the educational, and popular sides must, if possible, be carried on *pari passu*.

A MODIFIED BINAURAL STETHOSCOPE.

To the Editors of THE LANCET.

SIRs,—Binaural stethoscopes of the usual pattern must have struck everyone as being somewhat awkward—at least, in appearance. There being no apparent reason why the conducting air column should be divided immediately at the chest-piece I have had made a stethoscope in which the division takes place as near as practicable to the ears. The distal ends of the metal tubes curve inward instead of outward and are connected to the metal "Y" tube forming the junction by short lengths of rubber tubing. The advantages claimed for this over the usual pattern are: (1) greater convenience in use, (2) a neater appearance; and (3) increased compactness when folded and the shorter length of rubber tubing required. The alterations mentioned have been most satisfactorily carried out by the Medical Supply Association, 223, Gray's Inn-road, London, W.C.

I am, Sirs, yours faithfully,

J. INMAN LANGLEY, M.R.C.S. Eng., L.R.C.P. Lond.

April 5th, 1907.

THE ATTITUDE OF JURIES TO MEDICAL EXPERT TESTIMONY.

THIS matter has recently been discussed at length in the New York Court of Appeal in the case of *Kelly v. Wells*. The facts were as follows:—A builder's labourer fell some 20 feet and was crushed by falling building material, so that his left leg was fractured in two places, his right ankle was fractured and dislocated, and his left side was severely bruised. 25 days later he died suddenly in hospital, the cause of death being given as embolism. When the case came into court a recognised medical expert said that in the absence of a necropsy the statement as to the cause of death was a mere conjecture; other medical witnesses supported this view. The jury being thus in doubt

were directed that it was not their function in such circumstances to determine the exact and definite cause of death with the scientific precision of a physician, for the medical evidence adduced was inconclusive; upon the evidence and falling any apparent intervening cause they might find that the death probably arose from the injury. In this way the jury declined to discuss how far the expert testimony should be regarded as medical fact and how far it should be recognised as medical opinion.

ODD MEDICAL TERMS.

To the Editors of THE LANCET.

SIRS,—One frequently meets with bizarre renderings of medical terms among the illiterate, but I fancy the following must be unique and worth preserving. A woman called to consult me the other day, and on my asking her what she complained of I was astounded by this information, "the Cossacks has been very unreg'lar lately!" The gentlemen in question have always been considered irregular in their habits, but this is the first time I have heard of them having been observed so far south of the equator.

I am, Sirs, yours faithfully,

P. L. TOWNLEY, B.A., M.B., Ch.B. M.D.

Gayndah, Queensland, March 13th, 1937.

THE JONES HOMES AT SANDGATE.

THE Sandgate urban district council recently prosecuted before the Elham county bench Mr. Percy Harold Jones who with his family are the proprietors of a certain number of houses in Sandgate called the Jones Homes. These are used for the reception of convalescent tuberculous patients. The prosecution was for committing an offence under the provisions of the Public Health Act by overcrowding at Ontario House and at Cambridge House. The case took two days to hear and as a result the justices came to the unanimous opinion that a nuisance existed and was likely to recur. They therefore made an order prohibiting the recurrence of the nuisance. This order was made with regard to both the houses. It will be remembered that we dealt at length with these homes in our issue of August 22nd, 1903, when they were under the management of Mr. J. J. Jones, father of Mr. P. H. Jones.

Veritas (R.A.M.C.).—It is impossible, from the information supplied, to say whether the prostatic abscess has burst into the urethra or into the bladder; but the point may sometimes be determined as follows. If, at the commencement of micturition, some unmixed pus is passed before any urine, then it is very probable that the abscess has burst into the urethra. If, on the other hand, the abscess has burst into the bladder the pus is intimately mixed with the urine. As the patient is improving rapidly it will be safe to let him sit up a little or even to take a little exercise in his room. He should not return to his work until the urine is clear, unless the cessation of the suppuration is very much delayed. Our correspondent does not say of what the "sediment" consists. Has it been examined microscopically? It would be as well to stain for gonococci.

S. G. B.—Moneylenders' circulars are a nuisance to us all. The one which our correspondent incloses is no more likely to catch the unwary than those issued by other members of the fraternity.

Blackpool.—Will our correspondent who has sent us an unsigned letter about a communication on heroin kindly send us his name?

M.R.C.S.—We think that in the circumstances described by our correspondent B would be within his rights to attend the patient.

M.B.—Our correspondent has omitted to enclose his name and address.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

An original and novel feature of "THE LANCET General Advertiser" is a Special Index to Advertisements on pages 2 and 4, which not only affords a ready means of finding any notice but is in itself an additional advertisement.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a receipt for the same.

Answers are now received at this Office, by special arrangement, to advertisements appearing in THE LANCET. The Manager cannot hold himself responsible for the return of testimonials, &c., sent to the Office in reply to advertisements; copies should be forwarded.

Cheque and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Office, 423, Strand, London, to whom all letters relating to Advertisements or Subscriptions should be addressed.

THE LANCET can be obtained at all Messrs. W. H. Smith and Son's and other Railway Bookstalls throughout the United Kingdom. Advertisements are also received by them and all other Advertising Agents.

ADVERTISING.
